

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

Lectures

ON

THE DIAGNOSIS OF INSANITY.

By THEO. B. HYSLOP, M.D.,

Lecturer on Mental Diseases to St. Mary's Hospital Medical School,
Assistant Physician to Bethlem Royal Hospital.

In these lectures I propose to deal with some of the practical and controversial aspects of insanity, and to submit for consideration some hints as to the method of approaching, with a certain degree of confidence, those who are alleged to be insane. Attention to these hints will save much trouble, not only in your examination and diagnosis of the nature of the mental malady, but also in your subsequent experiences should they ever extend to the law courts. My purpose, therefore, is to point out some of the dangers and difficulties which stand in your way in dealing with insane patients.

The first point of importance is that you should, before seeing the patient, obtain all the details of the case from the friends. Sometimes this is no easy task. The relatives of insane patients are only too fond of disguising, or of entirely withholding, the history of an insane inheritance. I have often been told in most emphatic terms that such a thing as insanity has never been known in the family; whereas, on investigation, the whole family for generations had suffered from some form of neurosis. The friends are also fond of attributing the illness of the patient to some fall, shock, overwork, religious meeting, or other cause which no one need be ashamed of, rather than admit the existence of a family taint or predisposition. The parents of idiots are especially prone to assign as the causes of their children's defects, some accidental circumstances which in reality have little or no value as factors.

Another difficulty with which one has to contend is, the informants themselves may be eccentric or even insane. One lady who applied for the admission of her sister to Bethlem, gave a connected and detailed account of her sister's delusions, moral perversions, and tendencies to impulsive violence. Subsequently, however, I was told that the informant herself was the victim of delusions as to her sister, and, moreover, she was actually under certificates at the time she made the application, the sister being perfectly sound. On another occasion a lady described very graphically the sufferings of a friend, who eventually turned out to be the lady herself.

These few notes of warning as to the relatives of insane persons ought to be borne in mind, and it is well to suspend all judgment until you have interviewed the patient, i.e., wait until you have fully inquired into both sides of the question. Over and over again, patients tell us that their friends are insane, and, curiously enough, the friends also not infrequently assert that the obvious lunatic is as sane as anyone. Quite recently one of our patients escaped on account of the stupidity of the police. Being allowed out on leave with an attendant in plain clothes he gave the attendant in charge as a wandering lunatic.

One word more as to the informants. They may be aiding a malingerer. On one occasion a patient was brought into our reception room without the usual admission papers. The friends were very mysterious, and appeared to be unduly anxious to impress me with the fact that the patient was suffering from the delusion that he had been poisoned. On interviewing the patient, the most noticeable feature was a constant attempt at restlessness. The forced expression of the face, and the evident desire to impress me with his insanity, were noteworthy. The friends had followed me into the room, and hastened to explain the nature of the symptoms. After obtaining silence I said to the patient, "What is the matter with you?" He made no reply, but redoubled his exertions, so I said, "Unless you can tell me what is the matter I must ask you to go elsewhere." He looked rather foolish at this, and ventured to glance at his friends for some advice on the matter. After a few moments of painful and perplexed silence, during which *all the voluntary facial contortions had ceased*, he stated that he had been poisoned. "By whom?" I asked. "By my enemies," he replied. "Who are your enemies?" I continued. "That's my business," he replied. "How do you know they poisoned you?" I asked. "Oh," he replied, "I saw them put it into my beer." "And yet you drank the beer all the same," I ventured to remark. At this the would-be patient, contrary to the usual custom of the insane, perceived the folly of his ways and lost his temper. After submitting to severe abuse from both friends and patient, and threats to make the matter public by means of the press, I suggested that since he had seen the poison put into the beer, and had voluntarily drunk it, the best thing he could do would be to go to St. Thomas's Hospital and get an emetic. Subsequently, I found that the would-be patient had endeavoured to avoid being summoned as a witness in an important matter then engaging the attention of the country.

This instance is of importance, and I may point out that insane patients do not argue in this way. Delusions as to poison are usually the result of many factors. Dyspepsia, or discomfort after food, is apt to be misinterpreted by the insane mind, and as a consequence some cause for the unpleasant sensations is sought, and poison is naturally suggested. The patient usually arrives at his fallacious conclusion from his own feelings, and it is not common to have such direct evidence brought forward. Moreover, the absurdity of the idea of a man voluntarily drinking a fluid containing poison was evident even to the patient himself.

To enter at length upon the question of feigned insanity would occupy too much of the time at my disposal. Ever since David "changed his behaviour and feigned himself mad, and scrambled on the doors of the gate, and let the spittle fall down upon his beard," there have arisen keen controversies as to whether apparent insanity is real or assumed. The presence of a motive, the history of the onset of the symptoms, and the inconsistency in the patient's conduct and statements, are the main points for your guidance. Sometimes absolute silence is maintained by the patient. Blandford says, "Comparing a true with a feigned case, I may say generally, that a real

lunatic, when approached by a stranger, appears at first rather better than worse, and more on his guard; he tries to bring his wits together and understand what is going on. But a sham lunatic when we go to him redoubles his efforts to seem insane; he is more energetically noisy, idiotic, and maniacal. Sham lunatics over act or under act their parts, and frequently declare themselves to be insane."

Epilepsy has been simulated, especially, by professional mendicants. The traditional use of a piece of soap to produce foaming at the mouth is of interest. One person, reported to have fits, when first aid was rendered, and the collar loosened, was found to have on his chest a placard stating, "Brandy always cures me."

Delusions are not uncommonly simulated, but it must also be remembered that the prolonged assumption of a delusion will sometimes end in actual insanity. This may come about in two ways. The malingerer may become exhausted through constant anxiety and forced attention to the *role* he assumes, or the constant repetition of his tale may result in a belief in its actual reality. Many of us, at times, imitate the mental aspect of the famous Bill Adams, who fought the Battle of Waterloo. We invent a yarn and improve upon it so often that ultimately we incorporate it as a part of our own actual experience. I do not, however, propose to push this argument too far.

Should I desire to assume the *role* of a certifiably insane patient, my first act would be to dissociate myself from others. I would allow my friends to discover for themselves some eccentricity of conduct or some strangeness of view, together with an attitude of melancholy and despondency. Having raised the element of expectant attention in those who are solicitous as to my welfare, the remainder would be easy. If I simulated an hallucination, I would let others discover it; if a delusion, I would be consistent about it, and teach people how to argue in a circle, and in spite of the evident fallacy in my reasoning, always return to the point from whence I started.

Attention to these matters will furnish any medical man with ample material for certification; but the certificate can be rendered more valid by some hint or attempt to commit suicide. In asylum practice, the worst cases with which we have to deal are those in which there is some confession as to suicide or homicide, and the element of risk adds to our desire to retain the patient under proper control.

Criminals not uncommonly plead forgetfulness of their crime, but it is often a difficult matter to decide. Many, however, have been hanged in spite of this plea, and from a practical point of view, it is far from being efficacious.

Being now fully aware of the possibility of deception on the part of friends and patients we will proceed to the examination of the patient. In the majority of instances it is advisable that you should be introduced to the patient as a medical man. Rarely is it necessary that deception need be resorted to. The relatives are only too apt to practice deception and to seek to introduce you as some old friend of one of the family, or as a man come to see about a dog, or some such frivolous pretext. Any system of deception seldom effects its purpose, and the patient will naturally resent being cross-questioned by a remote friend of the family or by a dog fancier. Moreover, if his suspicions be aroused, he is apt to refuse to submit to any examination whatsoever. It is, in my opinion, the wiser course to be strictly honest with all insane patients. You can effect more by means of a judicious consultation than by any other method.

I have been much impressed by the methods in which various members of the legal and of our own profession have first tackled patients. When the present Lunacy Act first came into force it was ordered

that either a magistrate, judge of county courts, or justice of the peace specially appointed under the Act, should, after seeing the medical certificates, sign an order for the admission of a patient to an asylum.

If not satisfied with the certificate these legal gentlemen had the right to personally examine the alleged lunatic. My first experience of one of these interviews was highly entertaining. The magistrate began by confessing to me that he knew nothing about lunacy, and had never seen a lunatic in his life. He was very anxious to know what he ought to do in order to test the patient, but I politely remarked that it would be presumption on my part to instruct him in his own business, so with many misgivings he entered upon his task. "Good morning," said the magistrate. The lady (who was remarkable for her serenity and capability of justly estimating men and matters) replied, "Good morning, Sir, but I have not the pleasure of knowing you." He at once proceeded to explain who he was, but she turned to me and said "perhaps you will tell me this gentleman's name." I did so, and the magistrate proceeded. "How are you, madam?" "Very well, thank you," she replied. "How are you?" "Oh, I'm all right," he said. "I shouldn't have thought so," she remarked. "you look peculiar about the eyes. Are you a male patient?" "No!" he replied. "I've come to inquire into your state of mind." "Look to yourself," she said, "and remember that I may excuse mere eccentricity, but I will not submit to impertinence." With that the magistrate flushed somewhat, but returned to the charge. "Madam, what I wish to know is, have you any delusions?" At this she rose and said, "Now I know you are neither eccentric nor rude. You are a poor ignorant man with little or no pretence even to common sense. Anyone could tell you that if I had any delusions, and knew they were delusions, they would no longer be delusions. Good morning to you." With that the interviews terminated.

I trust the magistrate has benefited by his experience. I have given this illustration because it represents a position in which you all may find yourselves unless you know how to set about eliciting facts. A patient should never perceive that you are searching for mental defects. We all naturally resent being cross-questioned as to our innermost thoughts by a perfect stranger. Therefore I submit that you ought first to play your part as medical men, inquiring into the conditions of bodily health, digestion, sleep, &c., then when you have convinced the patient that you really sympathise with his or her trouble, the road is easy to find out the mental interpretations of the disordered feelings.

There are three rules for the examination of patients, and unless you hold them ever before you, you will sooner or later find yourselves in the law courts with possibly the stigma of negligence attached to your action. These rules are as follows:—

1. *Test the Facts*, i.e., find out whether the statements of the patient are facts or not, and as part of this rule, you must decide whether the apparent mental perversion is the result of natural causes. In illustration of this point I may tell you some of my own experiences. One patient was admitted to Bethlem under a medical certificate to the effect that he was emotional, restless, crying bitterly, and that he stated that during the last week he had lost his father, mother, and sister. The medical man had actually neglected to test the statements. As a matter of fact, the statements were quite correct, and, moreover, the depression was but the natural reaction to such a series of losses. A man may suffer greatly at the loss of his relatives or become excited at the sudden acquisition of wealth. Did we not respond in some measure to ordinary influences our mental reactions would be defective.

A well-known specialist was lately consulted about an old gentleman who was apparently morbidly emotional and full of ideas of ruin. The patient declaimed bitterly that he was ruined, and that he had not a penny in the world. His wife on the other hand assured the specialist that this was far from being the case. "Indeed," she said "how could we keep up this large house and live as we do if we had not ample means?" In consideration of the ample means and the age of the patient it was decided to keep him at home under suitable nursing and supervision. The old man died in a few weeks and it was found that all his statements were correct. He had been living on trust money and his mental state was but a natural reaction after all.

And now, gentlemen, I wish to speak to you of a case which proved a very wholesome lesson to me. I admitted to Bethlem a male patient who had the following symptoms of insanity:—The patient left his home, came to London, went to a tabernacle, offered up a prayer, upon the sweetness of which he was complimented by various members of the congregation, immediately went to the Elephant and Castle, spoke to a woman of ill-fame and married her. Stated that his father was in the habit of committing unnatural offences, that he would set the Thames on fire, and that he had had communication with the dead. What with the patient's excited demeanour and attempts to do violence to all of us I did not hesitate in admitting him, and more especially upon such evidence as was given in the certificates.

When the excitement had somewhat subsided, however, he reasoned as follows:—

"All my life I have known that my father has committed unnatural offences, and of this you will have evidence from the authorities at Scotland Yard. At times I have been aware of sexual instincts in myself. Knowing that no decent girl would marry the son of such a father, and fearing lest I should give way to a morbid impulse which was ever before me in all its horrors, I determined that of two evils I would choose the lesser, and it was with this deliberate intention that I came to London, went to the Tabernacle to make my peace with God. Then I looked for the most suitable person, and (he said by way of an aside) I think you will agree that my wife is everything that could be desired."

On being questioned as to his state of excitement he replied, "How would you like to be shoved into a place like this the day after your marriage. Give a man credit for some show of energy." Again he continued, "What! I said I would set the Thames on fire, did I? Well, what of that? Have you never in your conceit thought you would set the Thames on fire? Perhaps you think I intended to light it with a match. You *must* be a fool if you take that in its literal sense." "But what about the communications with the dead?" said I. "My good sir," he replied, "if you're going to shut up everybody who believes that, what about all the members of my faith? I have been taught to believe that all my life, and it is no more than your own lot of *psychical research* people believe. How about them, with their *media*, and *telepathy*, and all that? Why don't you shut them all up?"

After a few days this patient was allowed to resume his honeymoon, and it was with great pleasure that I subsequently heard his marriage had proved far from being a failure. Although the episode occurred several years ago, up to the present time the loving couple have maintained a good standard of moral and mental rectitude.

The second point to which I would draw your attention is the

2. *Presence of Hallucinations or Delusions.*—In order to elicit the presence of either of these symptoms

it is absolutely necessary that you should proceed in a systematic way.

Just as you would first discuss the customary diet of a patient suffering from some abdominal complaint, so you ought to discuss the mental diet provided by the special senses in every form of mental disorder. The special senses provide the mind with food for reflection, and it is to their special consideration that I now propose to devote attention.

Unfortunately it is a common experience with us to have the whole nature of a case misrepresented, owing to neglect of the examination of the special senses. Many of the feeble certificates which we have, to do are owing to such neglect. Thus, patients have been described as preoccupied, inattentive, and morose, facts which are of little value in a law court, when a very little care might have elicited the presence of hallucinations of one or other senses, the mere presence of the hallucination itself giving a correct clue to the nature of the malady. As a matter of routine, I usually begin with the digestive organs and inquire about the functions of the whole length of the digestive tract. In many cases attention to this point will provide you with a true estimate of the case. Thus a patient may suffer from a foul taste in his mouth, difficulty in swallowing, pain after food, feelings of fulness, constipation, or other disorder. Having ascertained these facts, find out what the patient thinks of them. A foul taste may be the clue to ideas of poison and delusions of persecution. Difficulty in swallowing may be interpreted as due to the presence of organic disease, or there may be some other hypochondriacal interpretation. Pain after food may be attributed to the presence of cancer, snakes, or even the Devil. Fulness of the abdomen has been attributed to the presence of all sorts of abnormal influences, whilst constipation has furnished even some males with the idea that they were pregnant.

Attention to common sensation will reveal the existence of tinglings, twitchings, numbness, &c., and these very sensations are the clue to delusions as to electricity, and other influences thought to be at work. The paralytic who says he is in the habit of walking on air may receive the impression owing to anaesthesia of his feet. The woman who accuses those around her of persecuting her by batteries may have some feeling of pins and needles in her limbs. So it is with the sense of smell, sight, and hearing. Remember, however, it is with the interpretation of the actual sensations that you have to do.

In connection with this second rule I feel that I must tread upon ground which is of necessity mainly controversial. When we remember that our senses are very defective in many respects, and when we take into consideration the various illusions and hallucinations to which even the wisest of us are subject we must be generous and open-minded in our estimate of what is abnormal in others. Abnormal conditions of perception occur in the sane, in intermediate states between sanity and insanity, and in the insane. A false perception is technically called an illusion, and it must be borne in mind that the process is often largely the same in a false perception as in a true one. Some authors would seek the explanation of the fallacy in an illusion by taking into account the action of the senses only, and they would assume the mental interpretation of the false sensory impression to be the abstract result of a fallacy of the senses.

In the sane person there is a constant liability to errors of perception, illusions are common to us all. Our discriminating power is necessarily limited and defective. Thus the study of sensory perversions belong both to the psychologist and to the mental pathologist. There is no sudden break between the illusions of the sane and those of the insane, and there is often great difficulty in distinguishing between them. Our judgments are liable to be distorted at any time,

and our sensory discriminations may be at variance. Any emotional disturbance, any state of exhaustion, inattention, expectancy, or mental preparedness, may favour the development of some false sensory perception. The transition from sane to insane perceptions is often difficult to demonstrate.

In the *intermediate* conditions, half-way conditions between sanity and insanity, we have many examples of sensory disturbances. Thus, in some dream states, night-mare, religious fanaticism, and many excessive emotional states, we have perversions which are suggestive of a neurosis rather than true nerve health. In hysterical temperaments, especially, do we find illusory morbid conditions. In the sane the illusory percepts may be due to defective knowledge; or the illusory nature of the percepts may be recognised by the individuals in whom they occur as the results of defective energisation. In the intermediate states there is often failure to recognise the true nature of the illusory phenomena at the time of their occurrence, but this knowledge may be gained at some subsequent period.

In the *insane* there is not only a failure to recognise the true nature of the phenomena, but also a belief in their objective reality, and, as a consequence, there is a tendency on the part of the individual in whom they occur to act upon the false evidence presented to the mind by way of the senses.

In order to fully appreciate the influence of the various senses and their perversions of functions in the production of morbid perceptual processes, we ought to devote our attention more particularly to the consideration of the special senses themselves in their morbid objects. Time, however, will not permit this so I now pass to the consideration of actual delusions.

The imperfection of judgments formed by any individual may be due to

1. Imperfect observation.
2. Defective conditions of memory.
3. Imperfect use and conception of words.
4. The presence of emotional disturbances.
5. Traditions, i.e., attending to the notions of others.
6. Rapidity of formation.

Judgments may be correct or otherwise in respect of their mode of formation, but, if, when formed, they are persistent, they may become advantageous or the reverse. Thus, in every branch of science and literature we note the obstinacy with which erroneous judgments are adhered to, and the obstacles which they thus present to the advance of knowledge. A distinction has been made between *instinctive* and *reasoned* judgments. Professor James says a savage is often as tactful and astute socially as a trained diplomatist. Women's intuitions, so fine in the sphere of social or personal relations, are seldom good at mechanics. Most boys teach themselves how a clock goes; few girls. Whateley says woman is an unreasoning animal, and pokes the fire from on top.

In diseased states, the delusions of women, arrived at by intuitional processes, are seldom capable of correction by logical reasoning. The evolution of the mind in man differs essentially from that in woman. The woman at twenty has often formed her mental character in nearly all its essentials, and this remains through life, or, perchance, begins to develop from the reasoning side at the close of the reproductive period; whereas in the youth of twenty the reasoning faculty is undergoing active evolution, the mind is developing and endeavouring to assume a shape, is easily moulded, and deals little with intuitions as compared with reasoning.

The evolution of the mind of woman at the characteristic period I commend to your notice. It is from the ranks of such unfortunate sufferers that we obtain some deluded, but so-called strong-minded, individuals. They become platform orators, seek to redress their

grievances, subdue that reptile man, and, perchance, reform the empire generally.

As we have already seen, delusional states are often associated with illusions and hallucinations, but the presence of delusions does not necessarily imply a condition of mental weakness. Such patients are often shrewd and intelligent, memory good, volition strong, and they are able to keep their emotions well under control. In the sane we see every variety of delusion, arising in some instances from false sense-impressions or illusory phenomena, in others from the propagation of false intellectual beliefs, as in the various psychopathic epidemics, and as the result of ignorance. In the half-way conditions delusions vary from the effects of dreams or nightmare, to superstitious and false beliefs. Hysterical people are subject to temporary delusions, which are the outcome of emotions or loss of control. An insane delusion is usually defined as a belief in something that would be incredible to sane people of the same class, education, or race as the person who expresses it; this resulting from diseased working of the brain convolutions. An insane delusion affects the conduct of life, and is not due to ignorance.

In examining every case it is well to remember that delusions may arise—

- (1) In regard to an individual's self-consciousness. He may become exalted or depressed.
- (2) They may relate to the individual's physical organism, as the outcome of sensory disturbances.
- (3) They may relate to any part of the physical or social environment.

(4) Not only may a man feel that he has lost himself, and that he is someone else, but there may be an alternating condition, in which he believes he is at one time one individual, and at other times another. Or he may believe that he is two persons at once.

Now you will ask yourselves, what are the practical points for your guidance in recording the presence of delusions in your certificates? I would advise you to avoid such statements as the following:—

"Patient says I am a fool."

"Patient says he does not believe in the marriage ceremony."

"Patient says he feels depressed," &c.

As a matter of fact, practitioners who believe in life everlasting hesitate not in certifying a man who believes he will live for ever, and conversely, the believer in dust to dust consigns to an asylum the unfortunate being who says he is going to die. When a man accepts the declamations of his pastor and is at last convinced that his soul is lost he has only to mention his conviction to furnish the most common of all the certified facts indicating insanity.

We must be generous in our estimation of the feelings and beliefs of others, and I would caution you upon accepting their creeds as evidences of insanity. It is done daily, but, sooner or later, trouble will arise, and you may find yourselves in a ridiculous position in a law court, and figuring as a would-be judge upon matters which transcend the knowledge of even the most enlightened theologians.

One more caution I would give you.

The fact that hallucinations are exceedingly common in insane people is no argument that they are necessarily always insane symptoms. On the contrary, some hallucinations may be perfectly compatible with sanity. Who shall define the limits of interpretation of what appears to the mind? The materialist assumes the existence of a molecular causation to account for the origin of all objects of perception, whereas the spiritualist believes in spiritual factors. Who shall decide the issue and prove the sanity or insanity of these combatants? Until we are able to solve these ultimate problems, we must, as presumably sane individuals, be generous in the limits we assign to the interpretation which others give to their own experiences.

Unfortunately, many men define mental health from a purely objective standpoint. They make of it an objective description and not a subjective appreciation. The objective manifestations of the sensibilities, aims, beliefs, and characteristics of others, they regard from their own subjective standpoint. Their own functions, which they regard as sound, are compared with the objective manifestations of others, and any departure from their own standpoint is regarded as psychopathic, and not to be tolerated.

Of late years we have had a superabundance of literature upon the decay and degeneration of the human race. Were we to resort to the *argumentum ad hominem* we might see that these advocates of degeneracy are in reality degenerate advocates. They themselves adopt that weapon of rhetoricians and demagogues, the *argumentum ad populum*, in that they address themselves to the masses at large, and seek to excite their feelings by arrogant and insulting biographical details, which tend to prevent the formation of a dispassionate judgment upon the matter in hand.

Max Nordau might, from his writings, be described as a degenerate. He is not, however, an example of the genius who is degenerate, but of the gifted man who suffers from auto-hypnotism, and who appears to exhibit a condition of monoideism, which has been developed at the expense of his sense of justice and practical reason. I agree with Professor James that the real lesson of the books upon degeneration and genius is that we should welcome susceptibilities, impulses, obsessions, if we have them, so long as by their means the field of our experience grows deeper, and we contribute the better to the race's stores; that we should broaden our notion of health instead of narrowing it; that we should regard no single element of weakness as fatal—in short, that we should not be afraid of life.

In another place (a) I have sought to condemn much of the farcical writing upon the subject of degeneration, and I there pointed out my belief that such writings were due to—

1. Want of true breadth of culture—i.e., a sympathy with art pursuits, literature, science, and religion, derived from something more than a mere superficial examination of the evidence thereof.
2. The difficulty of forming an opinion of the general question from any one standpoint, and under the light of any one set of traditions.
3. The fact that the causes and sources which are most vital can often only with reluctance be disclosed to a nerveless and unsympathetic public opinion.
4. Materialistic bias, and the consequent lack of healthy sociological determination of the will, seeing that the belief in the supernatural has always been almost universal.

And now, gentlemen, it only remains for me to mention the third rule for your guidance in the estimation of a case of insanity. The law requires that not only must a person think abnormally but there must also be some perversion of the conduct which renders the individual unsafe towards himself or to his fellow-beings, and thereby makes him a proper person for care and control. The third point, therefore, is to note the practical outcome of the mental perversion and how the patient's conduct is affected. At present the law is loth to recognise that a person may be insane in his conduct without at the same time having any actual discoverable mental defect. This, however, is a controversial matter which we cannot devote attention to at present. We have more to do with morbid conditions of action as we find them associated with mental perversions.

(a) "Mental Physiology."

Clinically, we have to note the following types of morbid impulse:—

1. General impulsiveness, or the tendency to react immediately to all sorts of external or internal stimuli. Patients of this type break windows, strike others, and are continually getting into mischief.
2. Epileptiform impulses which are unconscious in character, or in which, at any rate, the patient is unable to recall the reasons for, or the nature of, the impulsive act.
3. Sexual impulses, which include the excessive tendencies towards sexual intercourse, onanism, bestiality, &c.
4. Morbid appetites, in which patients are unable to resist eating and drinking all sorts of filth.
5. Homicidal or suicidal impulses.
6. Dipsomania, kleptomania, hyromania.
7. Impulsive conditions, which alternate with forms of intellectual or moral insanity.

These clinical varieties do not, however, include some of the most difficult cases with which you may have to deal. I refer to those cases in which the tendency to act out of conformity with our notions of social and moral rectitude is the result of the evolution of socialistic and other modes of reasoning. In dealing with such cases as these, my test is, and I venture to believe that you agree with me, to put the patient in the light of a sister, and then to decide whether you will sanction the meditated departure from the moral laws which civilisation has imposed upon us. It is needless to say I refer to an instance now engaging the attention of the public, in which the marriage laws are defied as being at variance with social freedom.

In subsequent lectures I purpose dealing in detail with the more important points in diagnosis, and in order to do so with some degree of completeness, considerable attention will be given to the various sensory illusions and hallucinations met with in the insane, and also to the mental perversions associated with defective memory, false conception, and disordered feelings.

THE EFFECTS PRODUCED IN THE RABBIT AND PIGEON BY THE EXTRACTION OF THE STAPES OR OF THE COLUMELLA, AND THE EXPERIMENTAL DESTRUCTION OF THE MEMBRANOUS VESTIBULE.

By PROF. GARNAULT, M.D.

[FROM OUR FRENCH CORRESPONDENT.]

A COMMUNICATION WAS read on the above subject at the last meeting of the Académie des Sciences, by Dr. Garnault.

In 1893 the author attempted extraction of the stapes in dogs and of the columella in pigeons. He took very incomplete antiseptic precautions, but suppuration occurred in only one case, and in that the animal made as good a recovery as the others. No reaction of any kind was manifested, and no complications, temporary or permanent, occurred.

The hearing of animals operated upon on both sides was notably diminished during about a fortnight, but at the end of two or three months it was difficult to distinguish animals experimented upon from those intact.

He destroyed also the tympanic membrane and cauterised it with nitrate of silver, so that it was not again repaired.

Having confirmed the previous experiments of Kessel and Botey, M. Garnault felt justified in practising on men extraction of the stapes, and he communicated to the Congress of Rome, 1894, three operations of the kind.

In a new series of experiments which he has made M. Garnault put on one side—only noting it incidentally—

the return of hearing, on which subject his experiments, as well as those of Kessel, Botey, and Straaten, left no doubt. He wished to take special note by personal observation of the effects upon the pigeon and rabbit of the operation which he wished to perform upon man, in which there is the danger of opening the membranous labyrinth. When the integrity of the auditory nerve has been proved by Rinne's test; and when it has been determined by examination by means of the probe, and particularly by centripetal pressure, that the stapes is fixed by bony ankylosis to the walls of its cell, indications for its removal exist; for it is known by experiments on animals that in extraction practised on man in comparable cases—that is, the auditory nerve being unaffected, but where there does not exist bony ankylosis of the stapes—membranous occlusion after operation of the fenestrum ovale, and the return of a high degree of hearing power is certain. Unfortunately, in these cases, the branches of the stapes become broken, when it is extracted by means of a hook; and it cannot otherwise be withdrawn without danger of opening the membranous labyrinth.

M. Garnault resolved to produce more severe lesions of this kind in animals. In pigeons he opened the membranous labyrinth by introduction of an elevator through the fenestrum ovale. In one pigeon he repeated the operation twice at intervals of three weeks. He did the same operation on rabbits, in which he extracted the stapes, dislocating and breaking it by means of a sharp elevator. When the labyrinth was opened in pigeons and rabbits the operation was never followed by serious or lasting effects on powers of standing, locomotion, or flight, nor was the general health affected. All the creatures thus operated on got well as soon as those from which the stapes alone had been removed. In pigeons the sense of hearing was re-established also in these conditions. It is extremely difficult to judge of the acuteness of the sense of hearing in the rabbit. The wounds healed just as well when no antiseptic precautions were taken as when these were observed.

In view of the important results to be derived from the operation, M. Garnault considers that his experiments justify extraction of the ankylosed stapes in the human subject when the rest of the necessary auditory apparatus is intact. Of course, the operation would be done with strict antiseptic precautions, and lesions of the membranous labyrinth, of which there is danger, could not possibly approach in gravity such as M. Garnault made experimentally on animals which, nevertheless, invariably recovered.

M. Garnault promises in a later paper fully to describe the structure of the membrane which closes the fenestrum ovale.

REAPPEARANCE OF MALARIAL AFFECTIONS IN DUBLIN: A WARNING.

By W. FRAZER, F.R.C.S.I., M.R.I.A.,

MALARIAL diseases were formerly known to occur in many parts of Ireland, and were reckoned among the common maladies that might be expected. I do not speak of the so-called "Malignant Fevers" termed by Gerard Boate, in 1652, "Irish Agues," some of which were possibly due to other forms of fever, and some also, it is probable, to malaria, as his description appears to show. He also distinctly mentions agues, for he states: "As for the tertian ague—some years since, I know not through what secret changes, it hath found access into the island, so that at this time some are taken with it." Certain it is that it continued in some damp districts, as for instance near Dublin at Swords,

along the banks of the river Liffey, at Island Bridge, at Bantry, and at the rere of Phoenix Park, where there was a wide extent of land saturated with water, first drained about forty years ago. The milder form of malarial disease, known as "Brow Ague," common in the city of Cork, and of late years, more frequent in parts of Dublin than it used to be, has never left us, but for a considerable time past, ague in any form would be thought more than rare.

I regret to say that an unmistakable example of summer-autumnal remittent fever, as witnessed in the South of Europe, came this autumn under my care, succeeded in its decline by symptoms of ordinary ague, and I have heard of another remittent attack, both patients living in Dublin. Possibly, if watched for, more of these unpleasant affections may be recognised. My case occurring in private practice, it is needless to give the detailed course of the malady. It was seen in constant consultation with another physician, and as the patient was unable to take quinine in any form, other treatment had to be employed. The remittent fever nearly lasted three weeks, then came a lull of about ten days. Subsequent to this marked attacks of ague set in. The patient is now convalescent.

PERFORATION IN ENTERIC FEVER ITS SURGICAL TREATMENT.

By FREDERICK HOLME WIGGIN, M.D.,

Visiting Surgeon, New York City Hospital.

THERE is no complication of enteric fever more dreaded by the physician than perforation. It occurs in about two per cent. of all cases. Its most frequent causes are improper diet, distension of the bowel from any cause, or too early and sudden movements of the patient. It is present as often in mild cases as in those which are severe and is most frequently met with in young adult males. As is well known, its recognition is not difficult. Its occurrence is announced by the advent in the course of the fever of sudden severe pain in the right iliac region, accompanied by symptoms of collapse, this being soon followed by the symptoms of peritonitis, and almost invariably on the second or third day the case terminates fatally. The site of the perforation is generally found to be in the last twelve inches of the ileum.

The late Prof. Loomis, in the course of the discussion on Dr. Reeve's paper on typhoid fever, read before the Association of American Physicians in 1890 said: "I do not remember to have seen a single recovery after there were unmistakable evidences of intestinal perforation. Recovery from a localised peritonitis, complicating typhoid fever, is not uncommon, but when characteristic symptoms of intestinal perforation are present, in my experience a fatal issue soon follows." With such evidence and our own individual experience of the hopelessness of the patient's condition when reliance is placed on Nature's efforts at repair (spontaneous recovery resulting less frequently in this than in other forms of perforation, on account of the central location of the injury), it is not to be wondered at that with the constant reports of successful operations for the relief of perforation from other causes and in other locations, the physician should turn toward the surgeon, asking if among the good tidings modern surgery is proclaiming to many sufferers there is not some message of hope for the unfortunates whose condition we are considering, who seem at present to be condemned to an untimely death, and by whose bed-sides he has so often stood with folded hands, helpless to aid them. Dr. Bontecou, of Troy, who was the first in the United States to operate for this form of perforation, claimed that "when this mortal accident occurs,

laparotomy cannot impair, but may improve the patient's chance of recovery." Dr. Van Hook, in his admirable paper reporting the first successful case of operation for perforation occurring in the course of a closely diagnosed case of enteric fever, remarked: "It is strange, nevertheless, that a question involving the only promise of help for five and seven-tenths per cent. of all those dying of typhoid fever should not have excited even more interest and discussion." Dr. Robert Abbe, (a) in a recent report of a case, also successfully operated upon, said: "Why one class of cases should be left to die, while we operate on all appendicitis cases, when perforation can be recognised, does not appear." Again, Prof. Kussmaul, of Strasburg, some time since, said: "Granted that the chance of a successful issue is heavily against you, that the patient is in the midst or at the end of a long sickness, that his tissues are in the worst state to stand the injuries of the surgeon's knife, that the lesions of the gut may be extensive, that the vital forces are at the lowest ebb, no one yet has hesitated to perform tracheotomy in the laryngeal complications of enteric fever which require it to save life, for these reasons."

With this testimony and much more that could be offered in favour of operation, one cannot help being surprised in looking over the literature of this subject, to find on record only twenty-four cases, of which six recovered. If those cases are rejected in which there is doubt of the diagnosis, we find only seventeen cases where an attempt has been made to relieve the patient's desperate strait by surgical means. Of these three recovered. Allusion has already been made to the first and third, and the second recovery belongs to Dr. Netschajau, of St. Petersburg. The writer's opinion, formed after a careful study of the subject, and from a considerable experience in abdominal operations when the patients were septic and consequently in bad condition, is that the physician on taking charge of a case of enteric fever should prepare himself to act with promptness on the occurrence of perforation. It is well to remember that while there should be the least delay possible these patients rarely die in the first state of collapse, and that this condition is not one favourable for operation. The patient as soon as the diagnosis is made should be stimulated by means of strychnia and morphia. If the patient rallies then the operation should be performed without loss of time, and under favourable conditions there is a fair chance of success, especially in those cases in which the course of the fever has been mild or where the perforation has occurred during convalescence. Of course, if the patient refused to respond to the stimulation the operation would be useless. Dr. Abbe, in the paper previously alluded to, said: "Very essential do I consider it that the surgeon should never be so hasty in getting at his work that he enters upon it handicapped by poor assistance, poor light, or poor arrangements for irrigation." While the patient is being stimulated the necessary arrangements for the operation can be made. The writer's experience has shown him that a laparotomy, although the personal care and trouble is greater, can be even more safely performed in a farmhouse with good surroundings than in a city hospital. All that is requisite is a clean light room, without carpet or furniture, except two or three wooden tables, an abundant supply of hot and cold soft spring water which has been sterilised by boiling, and a dozen towels.

Patients of this class do not bear anaesthesia well, and, in fact, the great danger comes from this source. With a closed inhaler of the Clover type, or Dawbarn's modification, which the writer has used with satisfaction for some years, patients can be readily anaesthetised and kept unconscious for an hour with four ounces of ether. The incision should usually be in the median line between the umbilicus and the pubes,

rather than over the site of the pain, true as this guide generally is to the point of perforation, for from this point one has the abdominal and pelvic contents under command. Search should first be made in the pelvis because collapsed small gut and extravasated matter tend to fall into this cavity, as has been pointed out by Bland Sutton (a). If the inflamed and perforated intestine is not found here the caecum should be sought, and the last foot of ileum is then easily located and looked over. When the injured point is found, the perforation should be closed if possible by Lambert's or Halsted's mattress sutures and should then be covered by an omental graft. The sutures for closing the abdominal wound should now be placed, all the layers of this wall being included. These sutures should be of silk worm gut. When this has been accomplished the abdominal cavity should be freely irrigated with a hot saline solution (half a drachm to the pint), about two gallons being used, the temperature of the water being from one hundred and ten to one hundred and fifteen degrees Fahrenheit, according to the degree of shock the patient is suffering from and in most cases the abdominal cavity should be left filled with the irrigating fluid, and the sutures already passed should be drawn and tied. If effort has been made by nature to shut off the perforated point by adhesions before they are disturbed the general cavity should be shut off by sponges or gauze. In some cases all that would be advisable to do would be to draw the perforated intestine into the wound, and after free irrigation of the abdominal cavity it should be stitched to the wound or surrounded by gauze, further procedure being delayed till a future occasion. In a still more desperate case, one occurring earlier, when the fever was at its height, or in which the fever had run a severer course, one might with the aid of cocaine anaesthesia rapidly open the abdominal cavity over the site of greatest pain, and after irrigating, surround the perforated intestine by gauze, thus shutting off the general cavity, favouring the formation of adhesions and securing drainage, as has been suggested by my friend, Dr. E. D. Ferguson. In one of the successful cases previously alluded to, Netschajau, a portion of the perforated intestine was excised, and now that an anastomosis by means of the Murphy button can be easily effected in five minutes, it may in favourable cases, especially in those in which a number of ulcers are near together and in a dangerous condition, be quicker and wiser to excise the diseased intestine. The decision as to the best procedure must be determined by the circumstances of each case and by each operator for himself. It is here that skill and experience count for the most. Personally, I favour closing the abdominal wound after free irrigation, leaving the abdominal cavity full of the hot fluid, as I know from many past experiences how much this procedure does to lessen shock and to prevent the danger of septic infection of the peritoneum. If at this time shock were still great, it would be wise to follow Dr. Abbe's advice to administer an enema of black coffee and whiskey on the operating table.

In conclusion, may we not all agree that in many cases of perforation occurring in the course of enteric fever an attempt should be made to save the patient by operation. The patient should be freely stimulated on the occurrence of this accident and careful preparation ought at once to be made for the operation. Time should not be purchased at the expense of experience, light or competent assistance. The smallest possible amount of ether should be used. The surgical procedure should be the least that offers hope of recovery to the patient. We must remember that the chance of a successful termination of our work increases with every drachm of ether and every minute saved. Finally, the physician must realise more fully that the surgeon

(a) *Medical Record*, January 6th, 1896.(a) "*Clinical Society Reports*," London, March 9th, 1894.

is his assistant and not his rival and must give him as well as the patient a fighting chance by calling him early and not after several days of hesitation which has too often been the case in this and other forms of intra-abdominal disease.

Under favourable conditions I am convinced that modern surgery has a remedy to offer these patients and that in the near future the mortality from perforation occurring in the course of enteric fever will be markedly lessened.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

MEETING HELD FRIDAY, DEC. 6TH.

The President, Sir THORNLEY STOKER, in the Chair.

THE SECRETARY, Mr. KENDAL FRANKS, asked if Mr. R. H. Woods would favour the Section with details of the very interesting case he had shown previous to the meeting, and upon the successful treatment of which he wished to congratulate Mr. Woods.

Mr. WOODS gave an account of the case of the man, *æt.* 28, upon whom he operated for extra-dural abscess in the cerebellar fossa on the left side, complicated by thrombosis of the lateral sinus, following middle ear disease. Two days later he again trephined him and evacuated an abscess in the left temporo-sphenoidal lobe. The man made an uninterrupted recovery.

Mr. WHEELER asked several questions about the case, to which Mr. Woods replied.

Mr. Woods then read a paper on

EXCISION OF HALF THE LARYNX.

The case described, said to be the first of its kind in Ireland, was one of malignant disease of the larynx in a man, *æt.* 32, whose dominant symptom was great pain in swallowing. There was no previous illness or history of syphilis; his father died of cancer of the neck. There was a tumour occupying the right half of the larynx and growing through the ala of the thyroid cartilage, so as to present externally. The glands were secondarily engaged; a piece of the tumour torn off proved to be a squamous epithelioma. Preliminary tracheotomy was performed and the right half of the larynx then raised. All the tissues from the great cornu of the hyoid bone to the arytenoid cartilage, inclusive, were removed. Two chains of glands were dissected out, a stomach tube was tied in, and the cavity plugged with iodoform gauze. The following day the temperature was 100.8° F., from whence it steadily fell to normal. The tracheotomy tube was dispensed with on the third day; on the 28th day the patient swallowed. After four months recurrence took place in a gland behind the clavicle. Its removal was attempted but without success, owing to air entering the veins. The patient died of pneumonia shortly afterwards, nearly five months after the excision.

Mr. CROLY thought that filling the wound with water was the best way of preventing canalisation. The difficulty of having oxygen always at hand was very much against its use in cases of emergency, such as of air entering a vein. He was rather sceptical as to the value of oxygen in such cases. He (Mr. Croly) desired to put three questions to Dr. Woods:—1. Why he did not remove the whole larynx? 2. Why he did not use water to prevent canalisation? 3. Why he did not ligate the jugular vein before proceeding to remove the glands adherent to its walls?

Mr. KENDAL FRANKS said Mr. Woods deserved to be congratulated on having described in a very interesting manner the details of an exceptionally brilliant operation. Unfortunately, the result was fatal, but death could not be ascribed to excision of the larynx; it was due to an extension of the disease, for the removal of which the operation had been undertaken. He believed he was right in describing Mr. Woods' case as the first undertaken in this country for the partial removal of the larynx. He had seen, in such a case, ether administered by the rectum,

but the patient died within forty-eight hours from colliquative diarrhoea, and the *post-mortem* showed acute inflammation of the whole of the large intestine. The administration of chloroform by means of Trendelenburg's apparatus through an opening in the trachea, as performed by Mr. Woods, was far better. He entirely disagreed with Mr. Croly's view that the whole larynx should have been excised. It made a great difference to the patient whether he lost his whole larynx or only half. Recurrence did not take place in the healthy side, but in the cicatrix, or in the glands of the neck of the affected side. Moreover, partial excision was far from being as dangerous as complete excision. Mr. Franks asked why Mr. Woods, in the second operation, did not tie the vein above and below, and remove the included portion with the adherent implicated glands.

Mr. WHEELER said that the rectal method of administering anaesthetics was not to be recommended. In one case that he had ether thus administered, the intestines became distended, pressed on the diaphragm, and considerably embarrassed breathing.

Professor BENNETT thought that a great source of danger in the administration of ether by the rectum was that the ether was apt to accumulate in the intestines, and therefore the quantity given was not easily controlled.

Mr. Woods, in reply to Mr. Croly, said that his finger introduced into the wound completely controlled the vein, and prevented the further entrance of air, and was much more rapidly effectual than filling the wound with water. The immediate improvement in the condition of the patient after the administration of oxygen, suggested oxygen as perhaps the best remedy for canalisation. The implicated glands were adherent not only to the internal jugular, but also to the subclavian and innominate veins, and the condition of the patient would not permit of such a serious proceeding as ligature and excision of these veins would involve.

A DISCUSSION OF SOME OF THE METHODS OF INTESTINAL ANASTOMOSIS.

Mr. MYLES in his communication described at length, and illustrated by a series of preparations, the methods introduced by Senn, Murphy, Mayo-Robson, &c. He discussed the merits and demerits of these various methods at some length, pointing out the special circumstances which seemed to him to be factors in determining the choice of any one method in any given case. His general conclusions were that simple suture alone, where possible, was the best method for end to end anastomosis. That for gastro-enterostomy, Senn's plates, fortified by a peripheral row of Lambert's sutures, seemed most promising; that the Murphy button was the readiest method of lateral anastomosis in the small intestine, and with care might be used for end to end anastomosis in the same situation, but that especial attention should be given to the turned-in portion of the mesentery when used for this purpose; that it should not be used for the large intestine at all, owing to the contents of the bowel being solid there. The operator should take great care to use a button not large enough to stretch the wall of the gut.

Mr. MYLES pointed out that all the methods now in use produced as a substitute for the contractile bowel an inert tube of cicatricial tissue at the point of junction.

The PRESIDENT said that one of the great questions as yet unsettled in surgery was whether we should prefer end to end or lateral anastomosis. For lateral anastomosis he was in favour of Senn's plates. He would not care to use Murphy's button to procure anastomosis above the ileocaecal valve. The button made of aluminium he considered superior to others. In a case in which he used Murphy's button in the colon, the patient died of septic peritonitis, which the *post-mortem* showed was due to sloughing of the intestine, extending both upwards and downwards, from the place where the button was inserted.

Mr. M'ARDLE believed that by far the best method of intestinal anastomosis was by the use of Murphy's button. The statistics which he had received from Mr. Murphy himself proved this. In 76 cases treated by methods other than Murphy's, 41 died. In 12 cases that were operated on for gangrenous hernia, and where Murphy's button was used, only two deaths occurred; and in 14 cases of internal strangulation its adoption was followed

by only one death. Taking 78 consecutive cases, we find there were only 10 deaths, although the list included many of great gravity. Mr. Murphy lays great stress on the necessity for closing the little triangular wound at the mesenteric border. By this means puckering is lessened and leakage prevented. A single case of stricture of the bowel following Murphy's method has not been recorded. Mr. Murphy insists on the button fitting easily into the lumen of the intestine. It should not, he says, be more than 15-16ths of an inch in diameter for small intestine. In his opinion Senn's plates were far inferior to Murphy's button. In returning the bowels into the abdomen the bowels should be placed in parallel rows, and the end containing the button should be placed most superficial.

Mr. KENDAL FRANKS said that end to end anastomosis by a continuous suture was the ideal method of treatment, and should be employed in all cases where urgency was not extreme. He did not attach much importance to the material of which the sutures were made, nor to the peculiar method of suture employed; but what he thought most important was, that the sutures should be made to pass through healthy tissue. Leakage was nearly always due to placing sutures in unhealthy bowel. A large amount of intestine—three, four, or five feet—could be safely removed if necessary, and it was better to take too much than too little. In cases of urgency, where the suture might take too long and might endanger the patient's life, he thought Murphy's button was the most useful contrivance, and deserved the place it occupied in surgery.

Mr. CROLY was favourably impressed by the small experience he had of Murphy's button.

Mr. MYLES having replied,
The Section adjourned.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD WEDNESDAY, DECEMBER 18TH.

Dr. W. CRAIG, Vice-President, in the Chair.

THIS meeting was devoted entirely to the exhibition of patients and specimens.

CASES.

Dr. ALLAN JAMIESON showed a girl, *æt.* 3, with Xeroderma pigmentosa. He explained that this was the second case of this disease reported from Scotland. The disease commenced in this child with some itchininess of the face followed by freckling. At present the skin of the face was much pigmented, with, in some parts, atrophic spots and warty growths. These warts were a special characteristic of the disease, and later on, became epitheliomatous, sometimes sarcomatous. In this case the face alone was affected.

Dr. MCGILLIVRAY showed: 1. A girl, *æt.* 7, in whom he had excised the condyles of the humerus for dislocation and fracture. 2. A lad, after thyrotomy for papillomata of the larynx. He generally performed a preliminary tracheotomy, and left the tube in for twenty-four hours after the other operation. The growths on the cords were easily removed, but those that sprang from the pouch between the cords presented much more difficulty. The bases of the warts were touched with fuming nitric acid.

Mr. J. M. COTTERILL showed—1. A girl on whom he had operated for a cyst of the pancreas. She had been ill for twelve weeks and exhibited a large swelling in the left hypochondrium about the size of a hand. Aspiration removed fluid. Following Mr. Cathcart he had operated from behind, making an incision just outside the erector spinae, and below the renal vessels. The cyst had thick fibrous walls. The patient was now quite well, for after three months drainage of the cyst, the wound had closed up very satisfactorily. 2. A boy, *æt.* 4, with a swelling in the sacral region which disappeared on pressure. The finger could be inserted into a hole in the posterior aspect of the sacrum, and, if introduced into the rectum could be felt passing through a large patency in the bone near where the swelling projected. Examination of the fluid drawn off from the swelling proved it to possess the characters of cerebro-spinal fluid. The boy was in other

ways deformed, in fact he was a museum in himself, for he had a clubfoot, a congenital inguinal hernia, ill-developed ears, some cardiac lesion, and an abnormally flexible elbow-joint, probably the result of an old fracture. 3. A woman who had come to him with a swelling of the cheek commencing in front of the ear. The presence of pus was diagnosed and evacuated. Later on granulations appeared at the mouth of the wound which on examination were found to contain the fungus of actino-mycoosis. The swelling had subsided to a great extent, but the question was, what was the correct treatment in the future?

Mr. CAIRD also showed three patients—1. A lad in whom a part of the humerus had been wanting owing to acute myelitis, and on whom he had operated successfully. 2. A boy, *æt.* 14, whose skull he had trephined for supposed meningitis over Broca's convolution on the left side. The patient had had a mastoid abscess which had been opened, and later on symptoms of meningitis set in. Nothing was found at the operation, but the boy became perfectly well a short time afterwards. 3. A lad on whom he had operated for dilated stomach. The pylorus was one inch in length and of the thickness of a slate pencil. The stomach held 80 oz. A longitudinal incision was made in the pylorus and stitched transversely together, while the stomach was made smaller by the stitching together of its reduplicated walls. The patient had been benefited by the operation.

Dr. J. THOMSON showed a case of Neuritis following measles, and one of Elephantiasis of the face, scalp, and neck.

Mr. WALLACE showed a patient who had made a perfect recovery after the evacuation of a large cerebral abscess involving the left temporo-sphenoidal lobe. The abscess had followed suppuration in the mastoid cells.

Mr. STILES show three patients; 1. A child with complete arrest of development of both ears. 2. A child with a cervical rib. 3. A child with symmetrical tubercular lesions, namely, osseous tubercles of the floor of the orbit.

Mr. ALEXIS THOMSON showed two men in whom he had excised portions of the fifth nerve for neuralgia. In one he had performed Rose's operation and called attention to the small amount of deformity resulting.

Dr. NORMAN WALKER showed four cases of lichen planus, one of leucoderma, and one of lupus vulgaris.

SPECIMENS.

Dr. BURN MURDOCH showed a piece of raw rhubarb which had caused intestinal obstruction in a child, and a specimen of caries of the stilo-axoid articulation.

Dr. A. JAMIESON showed the two parasites of ringworm under the microscope.

Dr. MACKENZIE JOHNSTON showed a boot button which had formed the centre of a rhinolith.

Dr. WALLACE: 1. Epithelioma of larynx, after complete laryngectomy. 2. Malignant double stricture of the oesophagus.

Dr. LEITH: Specimens illustrating a case of coincident simple perforating ulcer of the stomach, and primary colloid cancer of cæcum. 2. Two cases of malignant disease of the terminations of the common bile duct.

EXHIBITS.

Mr. CAIRD exhibited a portable steriliser for instruments.

Mr. STILES an improved tonsillotome (Mathieu).

LIVERPOOL MEDICAL SOCIETY

MEETING HELD FRIDAY, DECEMBER 12TH.

MR. CHAUNCEY PUZEY in the Chair.

THROAT CASES.

MR. BARK showed two patients after endo-laryngeal removal of Singer's nodule. They were both professional voice users. The first, a "star comique," had completely lost his singing voice. The growth had been removed in 1892, by another specialist, but recurred in about a year. He presented himself in July, 1893, and the growth was completely removed by means of Grant's guarded laryngeal forceps. Two weeks after the operation he fulfilled an engagement at Brighton, and wrote "that his voice had

never been better." Two years have elapsed without recurrence. The second patient, a choir-master, had suffered from hoarseness and loss of singing voice for over two years. The growth in this case also was removed by Grant's forceps, on the 29th June, 1894. His voice had been good ever since. Mr. Bark also showed a papilloma removed from the anterior commissure of the larynx by means of Gibb's snare, and a patient suffering from trachoma of the larynx.

Dr. STEEVES read a short note on

A RESPONSIBILITY TO THE LYING-IN PATIENT FROM A SANITARY POINT OF VIEW.

Puerperal fever now being a "notifiable disease" we no longer question the nomenclature from a public health standpoint, so long as the practitioner and sanitary authority do their duty under the Act: remarks confined to that variety of puerperal fever which exists as the result of defective sanitation. Dr. Steeves referred to instances where puerperal septicæmia existed as the result of atmospheric infection by sewer-gas. He touched on the result of removal of patients suffering from puerperal fever to healthy surroundings. In the city of Liverpool, one-third of the cases of puerperal fever reported occurred in houses which came under the category of insanitary. The prevalence of puerperal fever is no necessary index of the amount of zymotic disease. In Liverpool, in 1893, 82 cases of puerperal fever; in 1874, 68 cases. But there were many more cases of zymotic disease in 1894. A total of nearly 1,000 more in the latter year. The medical attendant when engaged to attend confinements rarely proceeds to the premises of the patient to investigate the sanitary conditions likely to affect the case ultimately. He pointed out the necessity where the owner refuses to abate a nuisance, of the physician calling the attention of the sanitary authority. Where the physician is without experience in sanitary detail, he should not hesitate to obtain a skilled opinion, a protracted period of ill-health, often conveniently passed as "general debility" frequently results after a confinement, the victim suffering from chronic sewer gas-poisoning, only got rid of by change of residence or alteration of sanitary arrangements. He then moved the following resolution, viz.: "That in the opinion of the members of the Liverpool Medical Institution, it is the duty of every medical practitioner when engaged to attend a confinement to forthwith inspect, or cause to be inspected, the premises of the patient, with a view of having any sanitary defects which may exist corrected, and so further the stamping out of puerperal septicæmia by the methods of preventive medicine."

SPINAL LOCALISATION.

Prof. SHERRINGTON, in a paper on this subject, drew attention to the localisation of function in the spinal cord, as illustrated by the distribution to the skin of the sensory spinal nerve pairs arising from the cord. He pointed out that experiments show the field of skin supplied by each sensory spinal nerve-root to be a large area of somewhat simple configuration. Where simplest, *e.g.*, in the trunk and neck the segmental skin-fluid is band-like, wrapping transversely round one lateral half of the body. In the limbs the spinal skin-fields are distorted from the simple band-like type. Further, in the limbs the spinal skin-fields are disconnected from attachment to the median line of the body, although in the trunk and neck each of the special skin-fields always extends from the mid-dorsal line to the mid-ventral line. In the regions of the limbs the mid-dorsal line of the body may be said to extend laterally in a side-branch forming a secondary axis almost at right angles to the main axis; upon this secondary axis, which may be called the limb-axis, the spinal skin fields are ranged, as though upon folded portions of the axial lines of the trunk itself. Each spinal skin-field spreads out to a marked extent into neighbouring spinal skin-fields. Each spinal skin-field has in this way an overlap into the next field in front and into that next behind. There is, therefore, no area of skin which is supplied by one spinal nerve above, and the supply is from two roots, in some places, *e.g.*, the palm (from three spinal roots, although in a plexus each sensory spinal root gives separate contributions to many nerve trunks, the cutaneous distribution of the root composes a field not of discrete or disjointed patches, but of

patches so-joined that the distribution of the entire root forms one continuous field.

Prof. PATERSON described the distribution of special nerves to the skin and muscles of the trunk and limbs of man. He pointed out that while superficially segmental in origin, the spinal nerves are truly segmental in distribution only to the muscles of the thoracic wall; and that where the segmental elements forming muscles have combined, the segmental nerves combine also, forming plexuses. With regard to cutaneous innervation it was certain that a certain overlapping takes place in the distribution of the simplest type of the nerve, so that it was possible to affirm that no spot of skin and no muscle (except the intercostal muscle) is supplied by a single spinal nerve. With this qualification the cutaneous innervation of the trunk between the limbs is zonular; continuous belts of skin are supplied from back to front by the branches of the third to the twelfth thoracic nerves. The nipple lies in the track of the fourth, the umbilicus in that of the tenth, nerve. The growth of the head and limbs causes the adjacent nerves to be drawn out of their primitive positions, so that the back of the head is innervated by C. 2 and 3; the buttock receives nerves from T 12 and L₁; and the buttock and back of the thigh nerves from S. 2 and 3. In the limbs lines (dorsal and ventral axial lines of Sherrington) could be drawn from the middle line of the body down the limbs, and indicated the meeting place of widely separated nerves. In the area the dorsal line separates the area supplied by third and fourth cervical from that supplied by second and third thoracic. The central line extends to the wrist, and separates the areas of distribution of C 3, 4, 5, 6. from those of 7, 8, and it is only at the ends of these lines that a continuity of distribution appears, and the seventh cervical nerve takes its proper place in cutaneous innervation. In the lower limb the dorsal line traceable over the buttock to the head of the fibula separates L 1, 2, 3. from S 1, 2, 3. The ventral line extends from the penis (supplied by L 1. and S 2, 3.) to the inner ankle and separate from above down, the areas in the front of the limb supplied by L 1, 2, 3, 4. from those on the back supplied by S 3, 2, 1. At the ends of these lines as in the arm the intervening nerves L. 4 and 5 or L. 5 make their appearance, and cause regular continuity of innervation of the leg and foot. It is seen in the limbs that in spite of the apparent complexity due to the combination of the spinal nerve in the plexuses and in the nerves of distribution, a definite arrangement exists by which the skin and muscles are supplied by a gradually descending series of spinal nerves proceeding from the preaxial to the postaxial borders of the limbs.

LARYNGOLOGICAL SOCIETY OF LONDON.

ORDINARY MEETING, WEDNESDAY, DEC. 11TH.

The President, Dr. FELIX SIMON, in the Chair.

CASES.

MR. C. BABER gave a further report of the case of papilloma of the nose shown before the Society last April. It had been thoroughly removed, and up to Nov. 29th had showed no sign of recurrence. Microscopical examination showed the growth to be a true papilloma.

Dr. J. B. BALL showed a case of soft fibroma of the left vocal cord.

Dr. CLIFFORD BEALE showed two pathological specimens of tubercular infiltration of the pharynx and tongue.

Dr. BENNETT showed a microscopical section of a round-celled sarcoma of the thyroid.

Mr. L. LAWRENCE showed a case of naso-pharyngeal polypus with nasal polypi.

Mr. DE SANTI suggested splitting the soft palate, and thus removing the growth.

Mr. C. Baber, Mr. Spencer, Dr. Dundas Grant, Dr. Permewan, Mr. Waggett, and Dr. Scanes Spicer all considered this a simple case of mucous polyp capable of being removed by the snare or polypus forceps.

Mr. DE SANTI showed two pathological specimens of tubercular ulceration of the trachea, larynx, and pharynx.

Dr. SIMON brought forward a case of a gentleman sent

from Australia, who had some ulcerative process in the larynx.

Dr. SCANES SPICER thought it was syphilitic.

Dr. W. HILL did not think it was either tubercular or syphilitic, and suggested it might be a kind of ulcerative laryngitis seen in some parts of Europe.

Dr. SIMON, in reply, said he had not yet made up his mind what it was.

Mr. W. G. SPENCER showed a case of stenosis of the larynx caused by a chronic inflammatory thickening.

A discussion arose as to whether the chronic inflammatory condition was caused by the nasal obstruction existing. Dr. De Havilland Hall and Dr. Scanes Spicer thought this was the case, but the President, Mr. Baber, Dr. Permevan, Dr. HILL, and Dr. Dundas Grant were of the opposite opinion.

Mr. STABB again brought forward the case of enlarged thyroid shown at the last meeting of the Society, the tumour had been removed, and the lad was doing well.

MR. W. R. W. STEWART showed a man, between 50 and 60, who had suffered from a very large tumour of the nose for twenty-five years. Last May, after an endeavour had been made to remove the growth by the ecraseur, Mr. Macready turned by the upper jaw performing a slightly modified Mansell Moullin operation. The tumour was found to be growing from the nasal septum, and on removal was found to measure 4 in. \times 2½ in. \times 1½ in. Microscopical examination showed it to be a true fibroma. It is by far the largest tumour of the kind on record.

The PRESIDENT suggested that a woodcut should be obtained for insertion in the Society's proceedings as the case was evidently unique.

Mr. J. SYMONDS gave a further report of two cases of lesion of the septum shown at the October meeting.

Mr. C. B. WAGGETT brought forward a case for diagnosis, a woman, *æt.* 54, giving a history of impacted fish bone with symptoms persisting for fourteen months.

Dr. W. A. WILLS showed a case of inspiratory spasm of the vocal cords.

was very great, and also in cases of grave septicæmia. M. Terrier thought that it was immaterial to make injections into the veins or cellular tissue, and recognised their efficacy.

TUBERCULOUS PERITONITIS.

M. Rendu communicated to the Medical Society a case of tuberculous peritonitis with ascites, in a lad of 17, in whom all bad symptoms had disappeared after tapping, followed by washing out the peritoneal cavity with eight quarts of hot sterilised water.

M. Sireday had a similar case in a girl, which he was going to treat by injections of camphorated naphthol as recommended by his colleague, M. Rendu, but remembering the remarks recently made by M. Netter, on the danger of this treatment, he put it off for some days, and in the meanwhile, to his great surprise, the symptoms began to disappear, and finally the patient left the hospital entirely well, without any interference.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, Dec. 27th.

At the Society for Nervous Diseases Hr. Brasch showed preparations of

EARLY SYPHILITIC DISEASE OF THE CENTRAL NERVOUS SYSTEM

taken from a man, *æt.* 47. The man was a gilder, and worked a good deal in lead. In his family there had been both mental disease and phthisis. The wife and children were healthy. He became infected in 1891. After three to four weeks a sore formed, which was of a phagedænic kind. He had acute stomatitis after a course of inunction, and the course had to be interrupted. Six weeks after inunction the patient had facial paralysis, which showed a severe reaction of degeneration. There was no lead line. In the beginning of November he complained of headache and giddiness. His appearance was bad, and he became still more cachectic. The paralysis showed no tendency to disappear. Transient contractions and Westphal's sign were observed. The paralysis was at first thought to be rheumatic, but when later auditory disturbances set in the suspicion of brain mischief arose. The patient had taken potass. iodidi. Small doses of mercury were now given internally. As the headache and giddiness got worse he was admitted into hospital. The disease affected the labyrinth, and was more on the right than on the left side. In about two months time he was discharged free from trouble, but in a fortnight the headache and giddiness returned. Inunction and pot. iodidi were ordered, and whilst these were being given left hemiplegia came on. The patient finally died with bulbar symptoms.

The autopsy was a surprise. Basilar meningitis and disease of the vessels were expected, but were not present, but instead, a purely vascular form of cerebral syphilis. The right pons was smaller than the left, the central ganglia normal. All the basilar arteries were greatly changed. There was secondary degeneration in the pyramidal tract, from the cervical medulla to the pons, but not passing beyond this. The peripheral nerves also showed changes. The period of the commencement of the disease was of special interest. The division into the three stages of the disease was not justifiable. The chief form of cerebral syphilis was the vascular and meningitic, and this

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, Dec. 28.

SEPTICÆMIA.

At the meeting of the Surgical Society, M. Pozzi read a paper from a colleague at Nice, on a case of septicæmia, treated successfully by intravenous injections of serum. A lady, on whom hysterectomy had been performed per vaginam, was seized on the third day with the gravest symptoms: enlarged abdomen, dyspnoea, intense low temperature, and vomiting. On the following day, the death agony seemed to have set in, when the surgeon made an injection of twenty ounces of serum prepared according to the formula of M. Hayem, and soon afterwards, another of thirty ounces. The patient for a short time was in a critical condition as a consequence of the injections, but soon rallied, and eventually made a good recovery.

M. Segond said that for a long time he was in the habit of improving the general condition of his patients who lost a good deal of blood from operations, by intravenous or subcutaneous injections of artificial serum. For the last four years, he did not perform any great operation without having recourse to these injections. He had injected as much as forty ounces of serum into the subcutaneous cellular tissue, and resuscitated in this manner many patients who would have otherwise succumbed.

M. Monod observed that he saw his house surgeon, last year, inject from twenty to forty ounces of serum with excellent results and without causing any accidents.

M. Michaux had frequently had recourse to intravenous injections in operations for fibroma when the loss of blood

was an early form. The infiltrations that formed at the base of the brain might later on thicken into gummatous formation. In other respects also we were not justified in distinguishing a secondary from a tertiary syphilis. In conclusion, the speaker formulated the following:—

1. Disease of the central nervous system is possible in every stage of syphilis.

2. This appears so much the earlier, as the treatment has been insufficient and attention to bodily wants defective.

3. As regarded disease of the nervous system there was no distinction between early and late periods.

At the Dermatological Society (Dec. 3rd) Hr. Litten showed a case of

DIFFUSE INTERSTITIAL SYPHILITIC HEPATITIS.

The speaker remarked that syphilis of the internal organs rarely came before the syphiologist, it generally went to the physician. Syphilitic disease of the liver was the common form of internal syphilitic disease, the easiest to examine, and the safest to diagnose.

Four forms of liver syphilis could be distinguished:—

1) Perihepatic syphilis, (2) the amyloid form of syphilitic disease of the liver, (3) syphilitic cirrhosis of the liver, and (4) diffuse interstitial syphilitic hepatitis. This latter form was first described by Wagner. The speaker had seen three cases. Anatomically there was diffuse growth of the connective tissue, which gradually pressed upon and took the place of the liver tissue. The newly-formed connective tissue had no tendency to shrink.

The consistence of the liver was that of a shoe sole (Trousseau) or that of a hearthstone (Gabler). He (the speaker) would describe it as polished ivory. This form developed for years without symptoms. Jaundice might or might not be present. Retrogression of the enlarged liver would take at least years. He had never proved that it took place. The patient shown acquired syphilis in 1870. Two years ago a relapse took place in the throat: the patient had then been under treatment eight weeks. He had felt the hardness in his abdomen for years. He had been treated by sublimate injection. Objectively, no change had been observed in the liver.

THE IMPERIAL HEALTH OFFICE.

In the Reichsgesundheitsamt the work to be done has increased so much that it is already beyond the powers of the present ordinary members. In addition to the duties already undertaken, experimental investigations have to be made into toxicological, pharmacological, and physiologico-chemical matters. Inquiries have to be made as to injurious consequences to health of certain industries, and in the preparation of certain foods and articles of consumption, and the skilled examination of drugs, with the view to another pharmacopoeia-medical-statistics, also require attention. Next year, another member, making the ninth, will be appointed, with a salary of 4,500 marks. The whole cost of the office for the year 1896-7 will be 277,550 marks, or 11,115 more than the year now ending.

THE SALE OF DIPHTHERIA SERUM AND THE GOVERNMENT.

The Minister for Medical Affairs has made the public announcement that after conferring with the principal manufacturers of diphtheria-curative serum, the Höchst Company and the Chemische Fabrik serum of higher strength than was formerly made may now be procured at the apothecaries. That for serum containing 300 units

per cubic centimetre, the price is 1.35 m. per centimetre; for that containing 400 units, the price is 2.40 m.; and for that containing 500 units, the price is 4 marks. It is not expected that the price will be reduced at present, even for charitable institutions.

LOCOMOTION OF GONOCOCCI.

At the Medical Society (Dec. 11th) Hr. Merre, of Chile, showed some microscopic preparation of pus cells containing gonococci. The latter showed an active movement independent of the current under the cover-glass. He made the observation that gonococci possessed independent movement in Hr. Lassar's klinik.

Hr. Hirschfeld gave an address on the

DIAGNOSIS AND COURSE OF DIABETES.

He did not distinguish the easily curable and the incurable form as two distinct groups of the disease, but only recognised one form in which variations for the better or worse were observed. Many intercurrent diseases increased the excretion of sugar, furunculosis, for example, whilst others, such as phthisis, diminished the proportion of sugar in the urine. Therapeutically, great individualisation was necessary, as the therapeutic factor acted differently in different individuals. A diminution of the excretion of sugar always followed the withdrawal of carbohydrates, but this result followed quickly in some cases and later in others. This diminished glycouria, however, was not at the same time an improvement of the condition, for many patients with an almost exclusive meat diet had serious attacks, especially coma. Over-feeding acted in the same way as under-feeding, i.e., unequally upon patients, and it was the same with muscular movement. The speaker then passed on to discuss drug treatment, and showed how uncertain this was also.

Austria.

[FROM OUR OWN CORRESPONDENT.]

Vienna, Dec. 27th.

EXTIRPATION OF THE UTERUS WITH PARAMETRIA.

At the Gesellschaft der Aerzte, Latzko exhibited a woman from whom he had removed the uterus with the adnexa. The patient had suffered from epithelioma of the portio which he determined to remove by a method which he claims to be his own. The principle on which he rests the claim of operation is the removal of the parametria which he believes to be the residual centre of a new outbreak of the cancerous condition, as the poison is carried to the lymphatics where new deposits are formed. For the perfect execution of the operation laparotomy is essential. When cutting round the ureters the sound should be used for their protection, the bladder dissected from behind, and the folds of ligament carefully removed from the ureter; the peritoneal covering of the posterior wall of the pelvis may then be carefully stripped, with the glands from the large blood vessels extending from the iliac down to the mouth of the ureters, while the broad ligament should be followed to its insertion in the walls and closely removed. The operation may be termed a general surgical one, recognised in removing a neoplasm, as the greatest care is necessary in taking away all probable centres of future origin. [He

considers it impossible to remove as thoroughly as should be, per vaginam, the whole extension of carcinoma as poisonous centres are sure to be left in the broad ligament.

Vertheim in criticising Letzko's operation said he could see very little novelty in the method as he thought Rumpf of Berlin had long since practised this form of removal. For the application of the sound in the ureter he could see little advantage of this as a careful dissection of the ureter can be easily performed without this difficult procedure. Again, he objected to laparotomy being combined with the vaginal method if no infiltration of the parametria existed. The opening of the abdomen was too serious an experiment to carry out on mere supposition. In seven of the cases thus treated by Schauta in his clinic, only two recovered and five died. It is even possible to remove by the vagina inflammatory or carcinomatous infiltrated parametria. Again, total extirpation by this operation will not secure immunity. A radical operation must include resection of the ureters which is not likely to be removed.

SUBPHRENIC ABSCESS.

At the *Doktoren Kollegium* Hermann Schlesinger traced the history of this morbid condition from the time of Barlan, 1845, to the present. He pointed out the difficulty of diagnosis and the necessity of confirmation by post-mortem. Leyden had put on record many useful observations, while France, in 1880, had added more difficulty by applying the term of false pneumothorax. The best monograph on the subject to-day is Maydl's. In the diagnosis there was no true point in auscultation or percussion to be relied on as the disease might arise from neighbouring organs lying in the vicinity of the diaphragm, such as the liver, pancreas, kidneys, retro-pharyngeal lymphatics, while the spleen is not to be neglected. On the upper side of the diaphragm the lungs, pleura, pericardium, and heart may be the starting-point of subphrenic abscesses. More remote causes may be found in the vermiform process or female organs—perforating injuries or metastatic causes. Winteritz showed a patient, on whom Maydl had operated on five years ago for subphrenic abscess. In July, 1890, she came to him with the phenomena of muscular rheumatism and left-sided pleuritis. The temperature was 38 degrees. Upon auscultation there was catarrhal vesicular breathing, with snoring and whistling râles; posteriorly there was a hand-breadth of dulness; the fever increased while pain continued. The persistence of the dulness, and the continuance of fever with asthenic pulse, and the absence of tubercle bacilli in the sputa, negated the diagnosis of phthisis; neither did the bacilli lend any confidence to the diagnosis of the latter. By exclusion the subphrenic process was diagnosed, but whether the morbid condition had its origin above or below the diaphragm was not so clear. Aspiration under the twelfth rib gave exit to a purulent discharge; a free incision was afterwards made. Washing applications of iodoform and glycerine with drainage brought about a good result.

The Operating Theatres.

ST. THOMAS'S HOSPITAL.

OPERATION FOR SUPPURATIVE PERITONITIS, SHOWING THE ADVANTAGES OF PROMPT SURGICAL INTERFERENCE.—MR. BATTLE operated on a young man, *æt.* about 21, who had been admitted a few hours before with symptoms of acute

abdominal mischief. He stated that three days before he had been opening a door and had struck himself a blow over his hip, which caused him to sit down rather suddenly on the ground. Soon afterwards he felt pain in the abdomen, which had since increased in severity, so that for two days he had been obliged to keep in bed. His bowels had acted and there had been no vomiting. When seen by the doctor he complained of the above symptoms, and was sent to the hospital, as the medical man told the patient he did not quite understand the nature of the case. On arrival in the wards he lay on his back, with his knees drawn up, complaining of pain in the abdomen, which was subject to marked exacerbations, during which he threw his head backwards and held his breath; he had a look of anxiety, and respiration was entirely thoracic, though fairly regular. The tongue and mouth were dry, pulse quick, and temperature 102.4; the abdomen looked normal, not being distended; the walls were rigid, and he complained of excessive tenderness, so that it was hardly possible to touch him. Light percussion was possible, however, and showed an area of dulness extending from the pubes outwards to about the middle of Poupart's ligament on the right side. This dulness was about an inch and a half wide above the spine of the pubes, gradually diminishing to the right. These symptoms were considered to be due to an early stage of suppurative peritonitis and operation was advised. The patient readily consented, so a median incision was made above the pubes in the middle line, the peritoneum opened and a quantity of pus about equal to half a pint evacuated; this occupied the pelvis and extended into the right iliac fossa, but was not shut off by adhesions from the general peritoneal cavity. The source of the mischief could not be demonstrated, but it was supposed that it was in the appendix vermiformis. The abdomen was washed out with sterilised water and a glass drainage tube put in. Mr. Battle remarked that this patient had been submitted to operation at an earlier period than was usually the case in suppurative peritonitis, as it was the custom for the physician to wait until the classical signs, including vomiting, had unmistakably proved the presence of peritonitis, when the patient was therefore exhausted, and unable to stand the necessary surgical procedures, when also considerable changes had taken place on the surface of the peritoneum; when the suppuration was widely diffused throughout the serous membrane, and it was difficult to disinfect the large surface affected, and the patient was suffering from the effects of absorption from such an extensive area. Many physicians would probably not consent to operation before vomiting had declared itself, but this case proved, he thought, the value of a combination of symptoms indicating suppurative peritonitis, which, taken together, form an urgent call for operation; this latter can alone save the patient, whose chances are greatly increased by promptitude in carrying out the necessary procedures. Only the week before he had, he said, been called upon to see a case of suppurative peritonitis while the symptoms were undoubted, but the patient, a boy, *æt.* 14, was so exhausted that he died twelve hours after a simple incision through the abdominal wall. In this latter case there had been two days' severe abdominal pain and then vomiting, which, at the time the boy was seen by Mr. Battle, was one of several symptoms which, while they indicated without doubt the nature of the case, showed also the extremely bad condition of the patient. This state is one, he thought, with which surgeons are only too familiar.

TREPHINING FOR COMPOUND COMMINUTED AND DEPRESSED FRACTURE OF THE SKULL.—The same surgeon operated on a boy, *æt.* 10, who had been kicked on the forehead by a horse an hour or two before. The hoof of the horse had struck him in the upper part of the frontal region, causing a transverse wound of the scalp, at the bottom of which a gutter-shaped fracture about three inches long and an inch and a half wide in its centre was visible. After the patient had been placed under chloroform the head was shaved and the wound and adjacent parts rendered as aseptic as possible. An incision was made at right angles to the wound and flaps reflected on each side above the fracture. A small trephine was then applied to the right of the middle line, and through the opening made by it an elevator was passed and the fragments of the bone elevated and removed. The inner table was especially comminuted. When the fragments were removed they were placed in warm solution of boracic acid. The removal of one fragment to the right of the middle line permitted free bleeding from a laceration in a large vein which was entering the superior longitudinal sinus; this was temporarily arrested by pressure and permanently by passing a suture round it so as to close the hole in the dura mater. The edges were smoothed with Hoffman's forceps, several fragments of bone, including the trephine crown, replaced, and the wound closed without drainage. Mr. Battle said that this was apparently another example of the ill results attending the pursuit of a game which was, so far as he knew, confined to Lambeth, and of which he had seen three previous examples, each of which might be described by the account given above of this patient; the game consists in striking a tethered horse on the hind quarters with a piece of rope or a stick and escaping before the animal has time to kick the striker. This proves the attraction which a game involving a considerable spice of danger has for the British urchin. All these boys, he said, ultimately recovered.

It is interesting to record, with regard to the case just described, that implantation of the bone was unsuccessful as the wound became septic, and a week after operation the boy developed symptoms of serious intra-cranial pressure, unconsciousness, dilated pupils, loss of power, especially on the left side, and lateral deviation of the eyes to the left with nystagmus; he was again taken to the operating theatre and the brain explored on both sides of the middle line. A small trochar and cannula was used; this was passed in all directions with a negative result. The former opening in the dura mater was then enlarged and a searcher passed between the dura mater and the brain; again the result was negative. The boy next day showed marked improvement and is at present convalescent.

By the appointment of Dr. David Nicholson as visitor of lunatics by the Lord Chancellor, the important appointment of medical superintendent of the Broadmoor Criminal Lunatic Asylum will become vacant. We congratulate Dr. Nicholson and the Lord Chancellor on the appointment.

DR. BERTRAM HUNT, of Harrow-on-the-Hill, committed suicide last week while in bed by severing the femoral artery. Dr. Hunt was staying at Christchurch, at the residence of a medical man, and he was suffering from depression.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 1, 1896.

EXTRA-GENITAL SYPHILIS.

THERE appears to be a very general impression that the consequences of syphilis contracted elsewhere than on the genital organs are graver than after the usual method of inoculation. The question has been very fully dealt with by Dr. Fournier, in a recent article, published in *La Semaine Médicale*, from which it would appear that extra-genital chancres do not involve a degree of severity or duration greater than in the ordinary form. Statistics show that the proportion of extra-genital to genital chancres is about seven per cent., that is to say, of a hundred cases of chancre of every description, the lesion is located on the genitals in ninety-three, and at some other spot, in six or seven. It would not be surprising if extra-genital chancres did really give rise to severer manifestations than those following lesions on the genitals where their appearance is sure to attract attention with a view to recognition and treatment. Owing to their unusual situation and other circumstances, it is a fact that extra-genital chancres often remain unrecognised, and, therefore, untreated, much longer than would be the case under ordinary circumstances. Syphilis from vaccination is universally in bad repute, and the history and the

mortality of certain epidemics which have occurred in France tend to support this view. On examination, however, we find that it is the age and condition of the little patients that are responsible for their mortality, plus of course the fact that in the earlier cases no treatment was instituted for a long time, simply because the disease was not identified. Digital infection in medical men has furnished a harrowing list of untoward results, but here too there are circumstances independent of the method of inoculation which may serve to explain why it is that digital syphilis sometimes paves the way to unusually severe tertiary symptoms. First of all a medical man is invariably a bad patient. He either has not treatment enough or he has too much, to which must be added the profound mental depression which the discovery can hardly fail to produce in one who is fully cognisant of the far-reaching possibilities of the disease. Then, too, it is highly probable that the generally received opinion has been built up on a few striking instances. The only way to settle the question was evidently to collect a sufficiently large number of figures and proceed to make a reliable comparison. The method selected by Dr. Fournier consisted in collecting a large number of cases of syphilis of all kinds at the tertiary stage, in which the symptoms were grave, and ascertaining how many of extra-genital origin. Now, of 1,200 cases with tertiary symptoms, 1,125 were due to genital syphilis, and only 75 to extra-genital chancre. This gives a proportion of 6.25 per cent. of extra-genital chancres; in other words, the proportion of patients suffering from tertiary symptoms is almost exactly the same as that of its occurrence, on an estimate based on some 10,000 cases. Just as there are six or seven extra-genital chancres among a hundred cases of chancre of every description, so in every 6 or 7 per cent. of every hundred cases of syphilis, the disease runs its course to the tertiary stage. Had the ratio of tertiary symptoms occurring in persons whose chancres were extra-genital been higher than the ratio of their initial proportion, then there would have been some ground for supposing that this form of infection was more disastrous, but this has been shown not to be the case. The gravity of syphilis in a given case is manifested in two ways, either by the premature outbreak at an early date of tertiary, usually multiple, symptoms, supervening immediately, or within a short time, after the appearance of the chancre, or by the supervention at a later date of tertiary phenomena, which are serious in that they attack one or other of the vital organs. Of 242 cases of prematurely grave syphilis Dr. Fournier found that the disease originated in the genital organs in 223 cases, and in only 19 instances in some other part of the body. Extra-genital syphilis thus comes out at 7.8 per cent., a result not materially different from that of the comparative frequency of the two methods of inoculation. Still another test is available in respect of the proportion of syphilitics who suffer from syphilis of the brain. Collecting all the cases of cerebral syphilis in which the situation of the primary chancre was known the author found that of 707 cases 31 were of extra-genital

origin, that is to say, 5 per cent. It appears, therefore, that the proportion of cases of cerebral syphilis following extra-genital chancre is less than it should be if its gravity were even equal to that of ordinary syphilis. Dr. Fournier is careful to observe that he does not express any opinion that there is no difference between genital and extra-genital infection, but he points out that though the two varieties of infection are strictly alike in symptomatology and prognosis, certain special cases of extra-genital syphilis do not follow the usual course. This peculiarity, however, in no wise depends on the localisation of the initial chancre, but upon the greater or less facility of diagnosing the condition and treating it. From this point of view tonsillary chancre is particularly dangerous, but the observation is also applicable in a less degree in respect of mammary and digital chancres. Dr. Fournier concludes that unquestionably syphilis of extra-genital origin does in some cases assume an unusually grave character, but taking them altogether the prognosis is not more gloomy than that of syphilis of any origin. When such cases prove unusually grave the exceptional gravity is due not so much to the extra-genital localisation of the primary chancre as to variable conditions under which the sufferer happens to be placed in respect of age, predisposition, individual power of resistance, soil and surroundings.

THE GIANT STRIDE OF SCIENCE.

ONE of the most striking characteristics of the present age is the rapidity with which mankind adopts new ideas and discoveries. The scientific toy or marvel of to-day becomes the established necessity of to-morrow, and is exploited by a thousand speculators in a keen commercial world. Although of late years men of science undoubtedly secure a larger portion of the wealth they are the means of creating, yet in the majority of instances it is still true that the lion's share falls to the mere manufacturer and distributor of their scientific wares. The latter fact has been over and over again illustrated in the history of inventions. To take a single instance, a few months since the death of the inventor of lucifer matches was reported from Saint-Lothaire, in Jura. This benefactor of his species was a poor country doctor, named Sauria, who, when a student at the College of Dôle, conceived the idea of making matches with chlorate of potash, sulphur, and phosphorus. He was, however, unable to raise the 1,500 francs necessary to patent his discovery. His researches became known to M. Nicolet, Professor of Physics at the college, who afterwards lectured upon the subject in Germany. The Germans developed the idea and ultimately imported matches into France, where they were called *allemandes*. It would be difficult to hazard a conjecture as to the enormous sums of money that have been made out of this invention. But the discoverer of the gold mine died in poverty at the age of 84. When an old and worn-out man he obtained from M. Grévy, at that time President of the French Republic, a government appointment as the keeper of a tobacco shop. It would nowadays be hard

to imagine a civilised world without matches, yet, if we may accept the foregoing account as true, it is sixty-four years only since the time of their first production by Dr. Sauria. Nor is the present generation much further removed from the birth of another marvellous invention, namely, the steam engine, which has probably had more to do with the giant stride of modern science and civilisation than any other single product of the human brain. Yet it was only last summer that the death of the driver of the first "locomotive" in England was commented upon in the public newspapers. It would take a large volume to describe even briefly the wonderful inventions in machinery of all kinds that have been issued in a steady stream of upward evolution since the days of the primitive engine "Puffing Billy," which is still preserved as a sacred landmark and relic among the national treasures at South Kensington. Curiously enough, the date of the first meeting of the British Association coincides with the year assigned for the discovery of lucifer matches. The progress of scientific knowledge during the ninety odd years that have since elapsed has been simply phenomenal. This attractive topic furnished the theme of the address by Sir Douglas Galton, President of the Norwich meeting in 1895. He pointed out that the Association early recognised the importance of uniformity in the record of scientific facts, as well as the necessity for an easy method of comparing standards and of correcting differences between individual observers. Indeed, the provision of accurate standards, not only of length, but of weight, capacity, temperature, force, and energy, are amongst the foundations of scientific investigation. In a former presidential address, speaking on this point, Lord Kelvin said, "Nearly all the grandest discoveries of science have been but the rewards of accurate measurement and patient, long-continued labour in the sifting of numerical results." It is not our intention to review, or even to enumerate, the chief scientific discoveries of the century that is now drawing to a close. The world is utilitarian, and men of science, by the very nature of their pursuits, dwell in the future rather than in the past. Sir Douglas Galton, in his Norwich Address, hinted at the lines of further physical research in the following eloquent passage: 'Who, at the foundation of the Association, would have believed some far-seeing philosopher if he had foretold that the spectroscope would analyse the constituents of the sun and measure the movements of the stars; that we should liquefy air and utilise temperatures approaching to the absolute zero for experimental research; that, like the magician of the 'Arabian Nights,' we should annihilate distance by means of the electric telegraph and the telephone; that we should illuminate our largest buildings instantaneously, with the clearness of day, by means of the electric current; that by the electric transmission of power we should be able to utilise the Falls of Niagara to work factories at distant places; that we should extract metals from the crust of the earth by the same electri-

cal agency to which, in some cases, their deposition has been attributed? These discoveries have been brought to their present condition by the researches of a long line of scientific explorers, such as Dalton, Joale, Maxwell, Helmholtz, Herz, Kelvin and Rayleigh, aided by vast strides made in mechanical skill. But what will our successors be discussing sixty years hence? How little do we yet know of the vibrations which communicate light and heat! Far as we have advanced in the application of electricity to the uses of life, we know but little even yet as to its real nature. We are only on the threshold of the knowledge of molecular action, or of the constitution of the all-pervading æther." This confession of humility and ignorance made by a veteran scientist may well find an echo in the schools of medicine. Although marvellous advances have been made during the past generation towards the goal of full and adequate knowledge, yet it may be doubted whether the pioneers of the medical profession have done more than catch the far-off glimpses of a glorious dawn.

THE DIRECT REPRESENTATION OF IRELAND IN THE GENERAL MEDICAL COUNCIL.

THE contest for the position vacated by the death of Dr. Kidd is likely to be very acute. The *status quo*, plainly stated, is as follows. The Dublin vote is, to a great extent, concentrated upon Mr. Thomson, who is in intimate relation with the College of Physicians and with the Trinity College Medical School, by virtue of his position as Secretary of the Royal Academy of Medicine, and he has, also, the sympathy of the same parties in the Council of the College of Surgeons. He is supported by these parties with additional enthusiasm, because he is believed to be the most dangerous opponent of Dr. Jacob, whom they desire, by all means, to defeat because he has striven to secure fair and honourable treatment for the Apothecaries' Hall in the recent controversy between that Body and the General Medical Council, in which dispute the College of Physicians has been the prosecutor. Mr. Thomson, being a Queen's University graduate, an *alumnus* of Galway College, and a Senator of the Royal University, had calculated upon receiving the solid vote of the Queen's College party in Belfast, Cork, and Galway, but his hopes have been to a great extent frustrated by the starting of Professor Cuming, of Belfast, who probably will carry off, from every candidate, the section of voters who are officially interested in the Queen's Colleges. Dr. Thomson has also such following throughout the country as can be picked up by the personal canvass of his friends.

Dr. Archibald Jacob will have in Dublin the following only of those who are disposed to give their vote apart from collegiate or school interests, and who are willing to believe that, rightly or wrongly, he has honestly tried to advocate what he thought best for the profession and just to all concerned. His chief dependence is upon the provincialists, whose battles he has been fighting for the past thirty years, and if he obtains their united support he will beat Mr. Thomson.

The desire that the direct representative should be one of the rank and file of the profession is represented by three candidates, Professor Cuming, of Belfast, Mr. Hercules MacDonnell, of Dundalk, and Dr. Greene, an esteemed practitioner at Ferns, and County Councillor in the Irish Medical Association, of whose candidature we were not aware when we last wrote. Professor Cuming may be eliminated from the category of representatives of the Irish country doctors. As a thoughtful, experienced teacher and practitioner, and a genial gentleman, no one could be fitter for the General Medical Council, but his past record presents no evidence that he has anything in common with the working practitioner. If the Belfast, Galway, and Cork Colleges can bring about his election they will have done an excellent stroke of business for themselves, and the Medical Council will be enriched by the accession of a member creditable to it as a collegiate representative. The other provincialist candidates are Dr. MacDonnell, of Dundalk, and Dr. Greene, of Ferns, of whom the only remark that need be made is that neither of them are likely to succeed, whatever their merits may be. We hope we shall not be mistaken when we make this observation. It must always be difficult to find a candidate outside the great teaching centres who will be *au courant* with the subjects of education, examination, and qualification with which the Medical Council is chiefly employed, and, at the same time well-informed and sympathetic with reference to the wants and wishes of the working practitioner; but if such a combination can be found in any competitor, and that a reasonable chance of success exists for such candidate, we think the aspiration of the provincialists to have a man of their own sort is very commendable. If, therefore, there is any way of concentrating the country votes of Mr. Thomson, Dr. Jacob, Professor Cuming, and Dr. Greene upon Dr. MacDonnell, or *vice versa*, we do not doubt that such candidate will win. Failing such means of concentration, it seems to us that the provincialists, by dividing their suffrages between four candidates, are simply making a present of the Direct Representation to a Dublin Collegiate nominee.

Notes on Current Topics.

Hydrophobia near London.

ALTHOUGH no deaths have occurred from hydrophobia in the Metropolitan district, yet it is reported that 40 rabid dogs have been killed therein as against 12 in 1894, and 8 in 1893. These figures must be received with a certain amount of caution, as it is a common thing to pronounce a dog mad if he bite anyone and to kill the unfortunate animal forthwith. There can be no doubt, however, when a human being dies from so strongly marked and terrible a malady as hydrophobia. Last week, a case of the kind formed the subject of an inquest at Croydon. A City solicitor living at that place was bitten on October 27th last, by his own fox terrier. He recovered from the wound and did well until five days before his death, when he

suddenly became unable to drink. His medical attendant recognised the malady as hydrophobia, a diagnosis which was confirmed by Professor Ferrier. The same terrier bit other dogs and also several persons, of whom one, a girl, has been sent to Paris for treatment. A number of cases of rabies have been reported at Willesden, and a panic prevails amongst the inhabitants of the place. Up till the present time, no muzzling order has been issued in the County of London, although it is being enforced in the boroughs of Kingston, Richmond and Guildford, and in the counties of Middlesex and Surrey.

The London Asylums Board and Its Fever Accommodation.

At length the Metropolitan Asylums Board has made some practical effort to accommodate the fever-stricken poor of London. This winter there is very little small-pox, and the Board has for months past been urged to throw open the Gore Farm (small-pox) Hospital for Convalescents to ordinary fever patients. It was decided, however, a month ago, not to adopt that course. But further reflection has brought wisdom to the counsels of the members, and on Saturday last they determined, by a majority of 38 to 8, to admit scarlatina and diphtheria patients to Gore Farm. As the institution in question has permanent accommodation for 1,000 patients, its opening will materially reduce the immediate pressure. At the end of last week the Board reported 3,502 patients in the district hospitals, 2,786 of whom were suffering from scarlet fever, and 564 from diphtheria.

The Scientific Administration of Chloroform.

THE cause of those who advocate the careful and accurate administration of chloroform has received a lift at the hands of the Society of Anæsthetists, where the subject was recently discussed very fully on a paper read by Dr. Carter, of Weymouth, whose thoughtful contributions on this subject our readers have on various occasions had opportunities of considering. The question is really so very simple that it is a matter for some surprise that it should still be necessary to discuss it. Are we to go on administering a powerful and lethal drug such as chloroform in a haphazard way, trusting to the patient to give us due warning of an impending catastrophe, or is the anæsthetist to calculate the quantity required to bring about narcosis by means of a suitable apparatus? The fact that chloroform is given in thousands of instances by the rough and ready methods so frequently employed without a fatal result is not *per se* any reason why advantage should not be taken of the ingenious and convenient apparatus at our disposal, which allows of our controlling effectually and certainly the output of the vapour. Once again it must be repeated as a cardinal principle that death from chloroform means that the patient has succumbed to an overdose. In some cases, the overdose is singularly small in point of quantity, but that is, if anything, an additional reason for displaying the greatest possible care. Dr. Carter's paper was well received by the Society, and virtually received the

assent of nearly all present. We do not wish to tie anyone down to a particular procedure. It is rather the principle of accurate dosage that we are contending for, and in such a matter common sense ought, if necessary, to override special experience. A bad method in expert hands may give better results than a good method in careless or unskilled hands, but these considerations are *ultra vires* in discussing the principles that should underlie the administration of an anæsthetic. The fact, too, that the quantity of chloroform required to induce and maintain anæsthesia with a regulating inhaler is vastly less than by ordinary means, is of importance, for it is evident that *cæteris paribus*, the less chloroform absorbed by the patient the greater will be the freedom from risk and the various uncomfortable sequelæ.

The Registrarship of the London University.

THE Registrarship of the University of London will shortly be declared vacant by the retirement of Dr. Milman who has filled the office with great satisfaction to the authorities, the examiners, and all with whom he was brought in contact for many years past. The vacancy is likely to create a considerable amount of competition as there are naturally many privileges connected with such an appointment, added to which is the salary of £800, increasing to £1,000 per annum. The new Registrar will enter on his duties on May 1st, 1896, full particulars of which will be furnished by the present Registrar.

"Powders" for Cerebral Vomiting.

SOME curious facts were disclosed at an inquest held last week by a London Coroner. A lad, aged ten, entered into a competition with some playmates as to which of them could stand longest on his head. He subsequently grew dull and heavy and vomited. His parents procured some powders from the chemist to stay the sickness, but they had not the desired effect, and the child died soon afterwards. Medical evidence was given to the effect that the cause of death was serous apoplexy. The case is certainly an unusual one, and probably death might have been averted by prompt medical treatment. It illustrates the absurd faith pinned by ignorant folk to the prescribing powers of the dispensing chemist. For our own part we hold that a chemist like the above who gives medicines to treat serious specific conditions is deserving of short shrift and condign punishment. The coroner pointed out that the death could hardly be called accidental, while it certainly was not a natural one.

How Fever is Spread.

AN extraordinary state of affairs was brought to light a few days since before a metropolitan coroner. The object of the inquest was to inquire into the death of a child five months old. The mother said that all her children had been taken ill one after the other—the first about three weeks since, that they had come out in a rash, and had been about the whole time. Her baby seemed poorly, so she called in a doctor, who said the children were suffering from

scarlet fever. The father had been going to work, and the mother asserted she did not know the nature of the disease until the doctor was called. It is tolerably certain that this family must have spread the fever broadcast over a considerable area. In the face of such a revelation the labours of preventive medicine may well appear Sisyphean and hopeless. But the preventive machinery itself is at fault, for even after the discovery of this nest of infection there appears to have been the usual doubt as to their removal to an infectious hospital. A doctor present in court stated that he had two or three cases where he was unable to get the authorities to remove fever-stricken patients from one-room tenements. It would be more reassuring to the general public if the asylums board issued circulars dealing definitely with public statements of this nature.

Malaria.

OF late, the subject of malaria has been attracting a good deal of attention. The recent experiences of the French in Madagascar emphasise the havoc that this pestilential malady can work among troops that have not become acclimatised to its poisonous influence. It remains to be seen how our British soldiers will pass through a similar ordeal in their march of many miles through the heart of a tropical forest. Fortunately, the home authorities are alive to the necessity of fighting King Fever as well as the King of Ashanti. They have sent forward native bearers to prepare camps at stated intervals along the forest route. In every case the soldiers will be provided with huts, where they can sleep at a distance of at least two feet from the ground. Malaria is almost invariably contracted at night, but it would be clearly impossible to prevent the occasional exposure of men to night duty. Of course, the value of quinine taken as a routine prophylactic is well recognised. Eucalyptus is also recommended by some authorities for a similar purpose. News comes of a new remedy for malaria which has been brought before the notice of the French Academy of Medicine in Paris. It is an extract called Pombotano-Midi, obtained from a Mexican plant. Fortunately malaria, as a disease, is fairly tractable to treatment. Our War Office may reasonably hope for a minimum sacrifice of life from climatic causes. It has selected picked men and supplied them with the best of material for comfort and safety in camp, on the march, and in the field. With good food, suitable clothing, dry camps, proper pumps, and sterilising filters, we may hope for an instructive object lesson in the advances of modern military hygiene. The Indian sanitary authorities will do well to follow closely the history and experiences of the Ashanti expedition.

An Anti-vaccinationist Theory.

THE physician to a well-known London hospital for diseases of the skin vouches for the truth of the following incident:—A girl, of about seventeen years of age, was brought to him to be treated for irritation of the scalp of long standing. The friends of the patient declared that the condition first appeared after vaccination; that up to that time the girl had been perfectly

healthy, but that she had been ailing ever since. On examination the scalp was found to be in a shocking condition, covered with numerous ulcers and decomposing *débris*, and simply swarming with *pediculi capitis*. There could be little doubt that the parasites were the real *fons et origo mali*, and had kept up the trouble, which by its constant pain, irritation and discharges had considerably impaired the health of the unfortunate sufferer. This view of the case was presented to the patient's friends, but they refused to abandon their vaccination theory. Their story had been told so often and for so long a period, and had become so deeply rooted in their convictions, that it was not to be gainsaid by the simple statement of a hospital physician. Their theory amounts to the transmission of *pediculi capitis* or their ova in vaccine matter. In any case, it is not much more absurd than much of the evidence advanced by anti-vaccinationists. Unfortunately it is a fact that some rashes, for the most part fleeting and harmless, accompany or follow vaccination. There can be no doubt that the observance of strict aseptic precautions before, during, and after vaccination would do much to lessen these little complications, and to restore the confidence of that small but mischievous section of the community that constitutes the schismatic camp of the anti-vaccinationists.

Ladies as Hospital Managers.

A MOVEMENT is on foot in Edinburgh, and one which will, no doubt, give rise to a great deal of opposition on the part of those members of the profession who are anti-feminine in everything, to nominate a lady for the one vacancy on the board of the Edinburgh Royal Infirmary. The vacancy is among those elected by the contributors, Mr. R. A. Lockhart's term of office having expired. Miss F. Stevenson, who has already done excellent work on the School Board, has, we believe, consented to be nominated, and there is no doubt that, if elected, she would make an admirable member of the board. It is reported that the present members of the board do not relish the idea of having a lady colleague. The infirmary board has long and justly been celebrated for the splendid manner in which the affairs of this huge charity have been conducted by them, but it is no disparagement to them to suggest that, in some matters, feminine advice would prove of great value. It might be so in connection with the laundry, with the nurses, and perhaps with the cooking arrangements. The Board has hitherto left purely medical questions in a large measure to be settled by the medical managers, and this would probably continue to be the case in the future, so that the election of a lady on the board should not concern or affect the susceptibilities of the staff to any great extent. A lady manager will be an innovation, and it, maybe, will prove a blessing, but in order to preserve the infirmary from a ladies' committee independent of the regular board, such a timely concession will be of value.

Medical Certificates and the School Boards.

THE granting of medical certificates of inability to attend school where the facts of the case do not warrant any such certification must surely be an exceptional occurrence. This alleged practice, however, has formed the subject of a discussion in the public newspapers, and as usual several medical men have been found ready to rush into the breach. The Chairman of the Attendance Committee of the London School Board admits that it is only in rare cases that medical certificates are signed without due care, and he is careful to say he does not impute a want of confidence, skill, or good faith on the part of the profession generally. At the same time he brings forward the specific case of a certificate granted by a duly qualified practitioner, which was produced before a magistrate as evidence of the inability of a child to attend school. After prolonged inquiry, the School Board officer ascertained from the doctor himself that he had not seen the child, and that he gave the certificate on the strength of the mother's assertions. As might be expected, this statement of affairs drew a strong expression of opinion from the magistrate at the adjourned hearing, as to the worthlessness of such testimony. Now that attention has been drawn to the point it will be well in future for all medical practitioners to be most careful how they grant certificates dealing with the health of school children. In the hurry of practice the busy doctor is often inclined to accept his patients' statements without putting them to further proof. Such a disclosure as the one above mentioned, however, not only brings discredit to the profession generally, but is also likely to involve the individual practitioner in a regular whirlpool of worry and annoyance.

Professional Ethics and the British Gynæcological Society.

THIS society is now established on so firm a basis that it doubtless feels itself strong enough to promulgate a code of honour for its Fellows which it might be well perhaps for certain other societies to imitate. We understand that at the annual meeting to be held on Thursday in next week, the following resolutions of Council (dated February 28th and April 4th, 1895, respectively) will be submitted to the Fellows, with a view to their being added to the bye-laws of the Society:—1. That it is undesirable that any member of the medical profession practising homœopathy should be proposed as a Fellow of the Society. 2. That it is contrary to the ethics of the British Gynæcological Society that any of its Fellows should advertise their publications, or otherwise bring themselves before the notice of the public by advertising in any way through the medium of the lay papers. That circulars of the nature of an advertisement sent even to members of the medical profession generally would be regarded with disapprobation by the Council. Doubtless, the discussion of such "burning questions" will attract a very full attendance.

The Oyster Scare.

At a meeting of the Health Committee of the Glasgow Town Council held last week, Dr. Chalmers, one of the medical officers of health for the city, submitted a report containing his investigations into the cause of the outbreak of typhoid fever which followed the Stirling County Ball. He considered that no reasonable grounds exist for supposing that the oysters which were supplied at the ball, or any other article of diet which was consumed at it, had been contaminated before being sent to Stirling. It might be presumed that whatever had been the cause of the outbreak had been infected in that town by sewage gas or other foul air, and had thus led to the outbreak of fever. This report is only in part reassuring. The original cause has not been discovered, and the good name of the oyster is still left under a cloud.

The Army Medical Service.

OWING to the recent death of four retired medical officers no less than seven honours or rewards have been distributed in the Army Medical Service. One of the good service rewards of £100 has been divided between two retired Quartermasters of the Army Medical Staff—Honorary Major L. Gorman and Honorary Captain E. Enright. Two other rewards of £100 each go to Surgeon-General J. O'Nial, C.B., retired pay; and Surgeon-Major-General J. Warren, Principal Medical Officer, Bombay. The appointment of Honorary Physician to the Queen, vacant by the death of Surgeon-General J. Irvine, goes to Deputy Inspector-General R. Domenichetti, late Army Medical Department; and the two vacancies for Honorary Surgeons to her Majesty, in succession to the late Director-General Sir T. Crawford and the late Surgeon-General Sir T. Longmore, go to Surgeon-Major-General C. D. Madden, and Surgeon-General H. T. Reade, V.C., C.B., late Medical Staff.

Exit the Andrew Clark Memorial.

THE unhappy attempt to promote a memorial on behalf of the late Sir Andrew Clark, to which we referred some weeks ago, has now become a matter of history. The Committee of the Memorial have closed the Fund, and have handed the amount of £2,500, raised by subscriptions, to the Governors of the London Hospital to be funded for the present, as the nucleus of a sum for the provision of a new isolation block at the above hospital. The cost of this new block will be upwards of £12,000, so that there does not appear to be any likelihood of the undertaking being carried out for some time to come. A good deal of satisfaction will probably be felt at this result, and that the busy bodies who interested themselves to perpetuate Sir Andrew Clark's memory by inveighing contributions for such a purpose have failed in their attempt, for, obviously, to apply for subscriptions for a memorial to the late President of the College of Physicians, who was admittedly not a universal genius, seemed to be unnecessary, and a step which savoured more of too severely taxing the living for the dead than anything else. Sir Andrew Clark had his

reward in this life, which, we are quite prepared to admit, he thoroughly deserved. But he was only, after all, one of many who in their various spheres of life have simply done their duty. The principle of taxing the living for the dead is undeniably a bad one, and we trust that the failure, conspicuous as it has been in this instance, to promote a memorial object, will, from the publicity which it has obtained, act as a corrective on future occasions of the kind.

The Next Annual Meeting of the British Medical Association.

A SPECIAL meeting of the Council of the British Medical Association was held in London last week, at which it was decided that the Annual Meeting of the Association should be held at Carlisle on the 28th, 29th, 30th, and 31st July next, and the Council approved of the nomination of the Border Counties branch that Dr. Barnes, of Carlisle, be the President of the Association next year. It is proposed to have nine sections in Carlisle, and Dr. Barnes, Dr. Helm, and Dr. Maclaren, representing the local arrangements committee, have secured from the Carlisle School Board the use of the Lowther Street Board Schools for the occasion. They have also obtained from the governors of the Grammar School permission to use a portion of that commodious building.

Royalty and Continental Hospitals.

THE hospitals in Berlin were especially favoured during the season of Christmas just passed. The Empress Frederic, according to her annual custom, paid a round of visits to them and other charitable institutions. At the Emperor and Empress Frederic's Children's Hospital her Majesty was present at the distribution of the Christmas gifts. One hundred and fifty-six children received their presents from the Empress Frederic's own hands, and these included for each little patient a complete outfit of new clothes. After the ceremony Professor Virchow gave a brief account of the results achieved in the hospital with the antitoxin serum in the treatment of diphtheria. In the period from April to November, out of 335 children who suffered from diphtheria 305 had been cured. The mortality, which had formerly amounted to 43 per cent., had fallen to 9½ per cent. This testimony of the efficacy of the new treatment, coming from so high an authority, is noteworthy, and should be borne in mind by those who are disposed to question the results which have so far been published in this regard.

THE Metropolitan Asylums Board have decided to open the Gore Farm Small-pox Hospital to convalescent fever patients.

THE life of public officers is not all smiles and harmony. Dr. E. O. Pryce, of Bangor, last week resigned his medical officership of the workhouse, owing to "the worry and petty annoyances he had to put up with, which he had neither time nor patience to endure." It is a pity that our *confrère* did not postpone his resignation till after the soothing influence of Christmastide had been tried.

The New Factory Bill.

TO-DAY, January 1st, 1896, the new Factory and Workshops Act will come into operation. The introduction of this measure, it will be remembered, was one of the last introduced by the late Government under the auspices of Mr. Asquith, the then Home Secretary. The new Act is far more stringent and far-reaching than any that have yet been in operation in this or in any other country. The important principle of a cubic space allowance for workmen has been adopted for the first time. The main points of this fresh and important departure in modern factory legislation will be discussed at length in an early issue.

The Case of Surgeon-Major Clarence Smith.

THE Commission that has been sitting to deal with the case of Surgeon-Major Clarence Smith has concluded its inquiry, and the verdict will now be awaited with much interest. Although the hearing was *in camera*, it is possible that a report of the proceedings may eventually be published.

A COMMITTEE will assemble in Calcutta this month to revise the present Army cholera rules. The Committee will be composed of the Quartermaster-General in India, the Principal Medical Officer with Her Majesty's Forces in India, and the Sanitary Commissioner with the Government of India, associated with Mr. Hankin, the bacteriologist.

THE Local Government Board has assented to the proposal of the Chelsea Board of Guardians to appoint a second assistant medical officer at a salary of £70 a year and the usual emoluments, and that females be eligible as well as males for the post.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

1895 IN EDINBURGH.

THE past year has been marked in Edinburgh by great variations both in the death-rate and the weather. A severe epidemic of influenza in the Spring, commencing during a period of intense cold, caused the mortality, especially in the month of March, to rise to a very unusual height, while the amount of sickness in the city was enormous. In the latter months of the year, notwithstanding a widespread epidemic of scarlet fever of a mild type, the mortality was very low and the health of the inhabitants excellent. For several weeks the death-rate varied between 14 and 16 per thousand, and in the last week of the year was as low as 14 per thousand, a very low rate for the time of year. Little of importance occurred in connection with the hospitals of the city except the opening of the new buildings for the Royal Hospital for Sick Children. The Infirmary managers decided in the course of the year to proceed with the extension of the present buildings, thanks to some munificent legacies received by them, and in doing so determined that the special departments, at present much cramped for want of space, should be first attended to. The Town Council purchased ground for a new fever hospital in the southern suburbs of the city, and

propose to build a large hospital on it. In connection with the Medical School of Edinburgh, the various extramural lecturers combined to form under the aegis of the Royal Colleges a single corporation. It has not been a very successful year in the matter of students; the numbers, perhaps, have not fallen from those of the year before, but are much below high-water mark. The profession has lost several well-known members, among whom may be mentioned Dr. Brakenridge, Dr. T. A. G. Balfour, and Dr. Bruce Bremner.

DESTRUCTION OF THE EDINBURGH SMALL-POX HOSPITAL.—The temporary building—a wooden structure—in the Queen's Park, which for a long time past has been used as an isolation hospital for small-pox patients, was destroyed by the fire brigade on Thursday last by order of the Public Health Committee. The woodwork was saturated with paraffin oil, and a large quantity of shavings was laid down beneath the flooring at the east end of the two pavilions. Shortly after midnight, when the neighbourhood was quiet, a match was applied to the shavings, and in a few minutes the buildings were ablaze. The flames, in incredibly short time, travelled along the buildings, the wind being from the east; a lurid glare was cast upon the sky, and the general impression was that a disastrous fire had occurred. Many set out in the direction from which the blaze proceeded; and to them it was somewhat of a disappointment when the precise state of matters was explained.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

PROPOSED MEDICAL TITLES BILL.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Your correspondent "H. S.," in the last number of your valuable journal, makes a statement which is certainly not borne out by facts. He asserts that "at present there is nothing whatever to prevent an unqualified quack from assuming the title of doctor and adding M.D. to his name." I can only state that many successful prosecutions for this offence under the Medical Act have been conducted by the Medical Defence Union each year for many years, and that, in fact, we have never lost a single case. With reference to the appeal now pending, he also, with singular want of judgment, refers to, as it is, however, at present "sub judice," I will not follow his example, but await the result with equanimity. The Medical Act properly used is a valuable weapon, and our success with it up to the present time certainly does not cause us to regard it in the same light as your correspondent.

I am, Sir, yours, &c.,

A. G. BATEMAN, M.B.,
Gen. Sec. Medical Defence Union.

Dec. 24, 1895.

THE GENERAL MEDICAL COUNCIL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—On reading in your columns the remarks of Sir Richard Quain, as to the disabilities of the legal profession, I could not see that there was any reason for our being content with the present constitution of our Council. Some of us from Lancashire and Cheshire, who were present at its session in May last, certainly were not favourably impressed with what we witnessed. Had we been shareholders in an undertaking having in its employment or government 32,000 hands, we should not have felt satisfied in leaving it in the hands and under the control of such a body of men, neither should we have felt content that even the affairs of a city would be effectually managed with a similar body of men in its Council. We certainly

do hope that those members of our profession who can visit the Council Chamber during the session will avail themselves of the opportunity, *for the public have free access*, as they will then see how and by whom the business of the government of our profession in these realms is conducted. Surely there ought to be some limit as to age when elected. At our Manchester Royal Infirmary the limit for holding appointments is sixty. Is there any reason why some such restriction should not be adopted in our governing body? Surely hundreds of capable and reliable men can be found in the country under that age who have the necessary energy and ability which would command the respect and confidence of every man.

As to Sir Richard's remarks about the direct representatives many of us in this part of the country are of opinion that, if we had had more, we should have had a far more practical outcome of the investigation in reference to Medical Aid Associations than we can find in their report on that question.

One effectual means of bringing the medical officers of such trading institutions into line would be to have an annual registration, as in the legal profession that the president referred to. If the amount of the fee were five shillings, the Council would have an additional income of about £8,000. This would provide us with ten additional direct representatives, and leave a large balance to be applied to some other useful purpose for the benefit of the profession at large.

It is not necessary to dwell at length on the advantages that would be derived from an annual registration, but this one might be stated, that such men that I have mentioned would at once begin seriously to reflect that it would be absolutely necessary to put their houses in order. For the first year or two, there might have to be a prolonged session of the Council or its executive to inquire into the reasons why certain men should not be again licensed to practice, or whether their licences should be endorsed, both as a record and a warning, as is done by the magistrates in certain other licences. But as time went on and better discipline resulted, the extra sessions would become small matters, for members would always feel that they were under the direct control and supervision of the General Medical Council.

Yours faithfully,

G. H. BROADBENT.

Manchester, December 17th, 1895.

[Our correspondent appends to his letter, the names and approximate ages of the various members of the Council, varying from 35 to 76 years, but as this must necessarily be guess work, we have deleted this portion.—ED.]

THE NOTIFICATION OF DISEASES ACT— MASON v. HADDEN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The particulars of this action at law, in which a medical man was sued for damages in consequence of his having notified a case, under the Infectious Diseases (Notification) Act, which he had reasonable grounds for regarding as one of small-pox, will be within your recollection, also that a jury awarded damages to the plaintiff, but that on appeal, the verdict was reversed by the full court.

We were previously advised that any public discussion of the matter by the medical profession would be undesirable, fearing that doing so might in any way prejudice the case.

The judgment of the full court justifies Dr. Hadden and relieves him from any imputation whatever. In addition to the anxiety and trouble necessarily caused to him while the action was pending, the question of expense has to be considered. Dr. Hadden has already incurred a large pecuniary liability, and as he has fought this case on professional and public, as well as on private grounds, we feel that he should not be allowed to suffer any loss. Therefore, we readily ask our professional brethren to join in a subscription to meet any such expense.

The issues raised have had an interest far beyond an individual one, and have induced Dr. Hadden to contest the case on broad public grounds, for had the contention

of the plaintiff in this matter remained unchallenged, a blow would have been struck at public safety, as well as at the independence of medical men. If a physician is to be proceeded against for the discharge of a duty cast on him by an Act of Parliament passed for the protection of the public at large, it would seriously interfere with the profession in carrying out the law and in protecting the public as they are bound to do.

We feel that both the moral and substantial support of his profession should be accorded to Dr. Hadden in the trying position in which he has been placed. The Act referred to is already unpopular enough with many persons, and if a new terror in the shape of actions for damages against medical men for carrying out the duties cast on them, and for which they are made legally liable, be introduced, it is to be feared that many might be deterred from obeying the law to its full extent.

Subscriptions, limited to one guinea, will be received and acknowledged by James Craig, M.D., 35 York Street, Dublin, who has consented to act as Hon. Treasurer.

Signed,—

THOS. W. GRIMSHAW, President R.C.P.I.
THORNLEY STOKER, Kt., President R.C.S.I.
JAMES LITTLE, President Roy. Acad. of Med. Irel.
ASTIN MELDON, President Irish Med. Assoc.
HENRY R. SWANZY, President Dub. Branch, B.M.A.
E. H. BENNETT, Professor of Surgery, Dub. Univ.
WM. THOMSON, Senator R.U.I.

Obituary.

DR. GEORGE HUGH KIDD.

WITHIN the past week the profession in Ireland has lost one of its most notable men by the death of Dr. George Hugh Kidd, its Direct Representative in the General Medical Council. He was born in Armagh in the year 1824, the descendant of a family of Scotch settlers. He first entered on the medical stage as a student of the College of Surgeons and Trinity College Schools in Dublin, afterwards at Edinburgh University, where he took his M.D., obtaining a gold medal as the reward of his intelligence and exceptional diligence. On his return to Dublin he was at once appointed to be a Demonstrator in the Park Street Schools, where he lectured on Anatomy and Physiology until, in 1849, he was translated to the Peter Street School of Medicine, with which institution he maintained his connection as a lecturer for eight years. During this period of his career as a teacher he was rapidly building up the reputation as a practitioner and operator in obstetrics, which eventually developed into a European celebrity. Having been attached for some time to the Coombe Lying-in Hospital as Obstetric Surgeon, he became its Master in 1876, and held that office until 1883, with such satisfaction to those connected with the Hospital that, if the law had permitted, he would have been re-elected to the Mastership for a further term. The roll of the distinctions which he received at the hands of the profession and of scientific institutions is almost too long for the space at our disposal. He filled the office of President of both the Royal College of Surgeons and the Royal Academy of Medicine, and, in 1883, was "capped" by the University of Dublin with the degree of Master in Obstetric Surgery (*hon. caus.*). His pre-eminent quality as a diagnostician, and his unrivalled experience as an obstetric surgeon, secured for him the position of Consulting Obstetrician to several of the Dublin hospitals, and the appreciation of his attainments by bodies outside Great Britain was manifested by the co-option of him as corresponding Member of the Obstetric Societies of Boston, Washington, Berlin, and Edinburgh. Finally, the rank and file of his working brethren in Ireland testified their respect and confidence in him by electing him their Direct Representative in the General Medical Council in 1886, when that office was first created. Dr. Kidd's contribution to the knowledge of his speciality presents a remarkable record of originality of conception, expert judgment, and earnest work. He may be designated,

with truth, the originator of puerperal antiseptics; he was the most successful operator of his time for vesico-vaginal fistula, having scored a series of 17 successive successful cases with a single operation. He was the pioneer in Ireland of the use of the laminaria digitalis for dilatation of the os uteri, and also of lumbar colotomy, and he also introduced the use of nitric acid for intra-uterine medication. Dr. Kidd was one of a type of Irishmen who make their mark wherever they go. He had many of the characteristics of Sir Dominic Corrigan, being strong-headed and strong-minded, not very regardful of obstacles, but very determined to overcome them. He resided in the house formerly occupied by Dan O'Connell, and might have been a close relative of the Liberator, for he evinced much of the same capacity for governing men. He will be long remembered by his professional brethren and by the public in Dublin, in Ireland, and even throughout Great Britain.

MR. JAMES ROUSE, F.R.C.S.

We regret to announce the death, at the comparatively early age of sixty-six, of this gentleman at his residence in London, 2 Wilton Street, Grosvenor Place. He was senior surgeon of St. George's Hospital, and consulting surgeon to the Royal Westminster Ophthalmic Hospital. He received his medical education at the school of St. George's Hospital, was admitted a member of the Royal College of Surgeons, England, in 1851, and elected a Fellow by examination in 1863. He was a member of the Pathological and Clinical Societies of London. Beside the foregoing hospital appointments, he held the post of ophthalmic surgeon to the Eastern Counties Asylum for Idiots, consulting surgeon to the Hospital of St. Elizabeth and St. John, to the St. Anne's Royal Asylum, and to the School for the Indigent Blind. He was the author of papers on Rheumatic Iritis, and Acute Orchitis in the St. George's Hospital Reports, and of various other contributions to the medical journals. Deceased has not been in robust health for some time past, and much of his time had to be passed at his seaside residence near Worthing.

MR. JOHN CHIPPENDALE, F.R.C.S.

By the death last week of this gentleman one of the oldest, if not the oldest, member in the profession has passed away at the age of ninety. Deceased became a Member of the Royal College of Surgeons of England so far back as 1835, and in 1843, the Honorary Fellowship was bestowed on him. He received his medical education at University College and Paris, and after taking his M.R.C.S. he served for seven years as Surgeon in the Royal West Indian and Brazil Mail Steamship Company, on returning from which he settled down to practise in London. Mr. Chippendale was the first annual President of the Medical Society of University College, London; was for seventeen years surgeon to the Farringdon General Dispensary, and for six years lecturer on Anatomy and Physiology at the Hunterian School of Medicine. During the last few years he had retired from the practice of his profession to Upper Phillimore Place, Kensington, where he did full of years and much respected.

Literature.

SACH'S NERVOUS DISEASES OF CHILDREN. (a)

We have been attracted from the outset by this work. It is a conception on a fairly large scale of what is known and what ought to be taught regarding the nervous diseases of children. The author is evidently well up in his subject, and takes a comprehensive, masterly view of it, so that much of the best that has been contributed by writers at home and abroad is here referred to. Functional and organic diseases are arranged separately. Anatomy without cumbering the book, is made to elucidate the text by graphic diagrams and a not too elaborate text. The author rightly enlarges on the best method of examining children, on the scheme of examination to be adopted, and lays down rules. He wisely treats of diseases rare as well as frequent, merely to keep in view their possibility

(a) "Nervous Diseases of Children," by B. Sachs, M.D. London: Bell, Tindall, and Cox. 1895. Price 12s.

when questions of differential diagnosis arise. Works of this kind are frequently overloaded with anatomical and physiological descriptions, which are mostly transpositions and are not brought into coherent relationship with the rest of the subject. Here we have a chapter on the anatomy, physiology, and pathology of the brain, which is remarkably interesting and more instructive than usual, because of the author's beautiful arrangement of diagrams. Localisation of functions, of strands of nerve fibres, of nerve paths, and vascular supply are rendered comparatively easy. If we might take exception to anything in this portion of the book, it would be the reproduction of Schäfer's illustration of the "Distribution of Blood Supply at Base," which is rather perplexing alongside of Thane and Charcot's illustration on the opposite page. We looked for a larger exposition of the subject of tubercular meningitis, but on further consideration it seems that the author has given the salient points of the subject. The treatment of the nature and varieties of idiocy and imbecility ought certainly to have been more fully entered upon in a work of this kind, for these diseases belong very largely to the group comprised in the author's title. These objections apart, we must acknowledge that this work is one of considerable merit and originality, and one especially adapted to be readable and serviceable in the hands of busy practitioners.

Medical News.

Vital Statistics.

THE deaths registered last week in thirty-three great towns of England and Wales corresponded to an annual rate of 18.6 per 1,000 of their aggregate population, which is estimated at 10,591,530 persons in the middle of this year. The deaths registered in each of the last four weeks in the several towns, alphabetically arranged, corresponded to the following annual rates per 1,000:—

Birkenhead 17, Birmingham 23, Blackburn 16, Bolton 19, Bradford 18, Brighton 11, Bristol 13, Burnley 16, Cardiff 15, Croydon 13, Derby 13, Dublin 20, Edinburgh 16, Glasgow 19, Gateshead 14, Halifax 15, Huddersfield 15, Hull 15, Leeds 18, Leicester 19, Liverpool 27, London 18, Manchester 19, Newcastle-on-Tyne 19, Norwich 21, Nottingham 18, Oldham 21, Plymouth 16, Portsmouth 12, Preston 20, Salford 24, Sheffield 18, Sunderland 20, Swansea 17, West Ham 15, Wolverhampton 23. The highest annual death-rates per 1,000 living, as measured by last week's mortality were:—From measles, 2.4 in Birmingham and in Liverpool, 2.9 in Norwich and in Blackburn, and 5.5 in Salford; from scarlet fever, 1.3 in Salford; from whooping-cough, 1.5 in Birkenhead, and 1.6 in Leeds; and from "fever," 1.0 in Salford 1.5 in Norwich and in Sunderland, and 2.4 in Birkenhead. The death-rate from diarrhoea did not reach 1.0 per 1,000 in any of the large towns. The 105 deaths from diphtheria included 82 in London, 6 in Birmingham, 5 in Edinburgh, 5 in Liverpool, 4 in Manchester and in Newcastle-on-Tyne, and 3 in Sheffield. No death from small-pox was registered in any part of the Kingdom.

PASS LISTS.

Royal College of Surgeons of England.

THE following gentlemen having passed the necessary examinations have been admitted Fellows of the College. The names are arranged in order of seniority as Members of the College:—

- | | |
|--|---|
| Ferrand, Edward (I.M.S.), M.D. Durh. | Randall, Mart'n, M.D., L.R.C.P. Sutcliffe, William G., L.R.C.P. |
| Foulerton, Alex. G. R., L.R.C.P. Lond. | Barnard, Harold L., L.R.C.P.Lond. |
| Tanner, Herbert, L.R.C.P.Lond. | Smith, T. B. H., M.B.Camb. |
| Pisani, Lionel John, L.S.A. | Turner, William, M.B., L.R.C.P. |
| Ridley, Nicholas Charles, M.B. | Elworthy, Henry S., L.R.C.P. Lond. |
| Lace, Frederick, L.R.C.P.Lond. | Arnold, Gilbert J., L.R.C.P.Lond. |
| Leaf, Cecil H., M.B., B.C.Camb. | Dickson, H. A. D., L.R.C.P.Lond. |
| Curtis, Henry J., L.R.C.P.Lond. | Colby, Francis E. A., M.B.Camb. |
| Addison, Christopher, L.R.C.P. | Brown, Ralph C., M.B., Ch.B. Melb. |
| Ballance, Hamilton A., M.D. | Brodie, William Haig M.D.Ed. |
| Hainworth, E. M., M.B., B.S. | |

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ORIGINAL ARTICLES or **LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

LOCAL REPORTS AND NEWS—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

REPRINTS—Authors of papers requiring reprints in pamphlet form after they have appeared in these columns can have them at half the usual cost, on application to the printers before type is broken up.

READING CASES—Cloth board cases, gilt-lettered, containing twenty-six strings for holding the numbers of THE MEDICAL PRESS AND CIRCULAR, may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

DR. JAS. SHAW is thanked for his cases illustrating "The Localising Value or the Prominent Symptoms of Encephalic Disease," which will appear in an early number.

ANTITOXIN AND DIPHTHERIA.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The following extract has been made from the "Monthly Analysis of Sickness and Mortality Statistics in London" with a view to compare the mortality from diphtheria before and after the introduction of antitoxin treatment:—

Months.	1893.		Deaths.	Per cent.
	Notified Cases of Diphtheria.			
Sept. ..	1,528	..	308	.. 20.1
Oct. ..	1,698	..	319	.. 19.9
Nov. ..	1,770	..	455	.. 24.5
1895.				
Sept. ..	1,082	..	185	.. 17.6
Oct. ..	1,572	..	307	.. 19.5
Nov. ..	1,283	..	265	.. 21.4

I am, Sir, yours, &c.,
M. ALTDORFER, M.D.

St. Ann's Hill, Dec. 28th, 1895.

DR. MURRELL.—We hope to have space for your paper on "The Pharmacological Action of Purgatives" in our next.

MR. C. B. S. is thanked for the information which we hope to be in a position to supplement next week.

DR. B. A. L.—The facts appear to us to be unquestionable, but we shall be glad of verification to avoid the possibility of a mistake.

CURIOUS IF TRUE.

AN eminent West End physician at the other evening kindly gave a lecture of a professional though popular character in a poor neighbourhood, where wholesome medical advice might be deemed acceptable. For lack of other accommodation the lecture was given in a chapel. As some of the physician's patients and friends had got word of the lecture, a number of them drove down to hear it. The audience was sprinkled with fashionable people, and there was so much money in the "house" that the cupid of the deacon who had to move a vote of thanks to the lecturer could not be restrained. Here were sheep to be shorn for the good of the cause, and he was the man to do it. Accordingly, the worthy deacon unblushingly announced that he thought, as so many of their friends were present, they would like to help the cause, and to give them an opportunity of doing so a collection would be made. Up rose the physician in a state of fiery indignation to inform the audience that when he consented to deliver the lecture it was on the condition that it was to be free in every respect. Slapping his pocket with his hand, he added he did not intend to give one penny, and he hoped no one else would do so. Of course this outburst was received with cheers, and another deacon was put up to apologise to the lecturer and to withdraw the obnoxious proposal of his brother.—*The Birmingham Gazette*.

Meetings of the Societies

FRIDAY, JAN. 3RD.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, West London Hospital, W.—8.30 p.m. Dr. McCann: Diagnosis of Gonorrhoeal Inflammations (with lime-light demonstration). Dr. Cremon: the Treatment of Enterocolitis in Infants.

vacancies.

City of Dublin Hospital.—Housekeeper. Applications before January 15th, 1896, to the Secretary at the Hospital. (See advert.)

City of London Union Infirmary.—Dispenser. Salary £100 per annum and dinner daily. Application forms and further particulars of the duties of F. W. Craze, Clerk to the Guardians, 61 Bartholomew Close, London, E.C.

Cootehill Union, Drumm Dispensary.—Medical Officer. Salary £100 per annum, and £30 per annum as Sanitary Officer, with fees. Election January 6th, 1896. (See advert.)

County Asylum, Prestwich, near Manchester.—Assistant Medical Officer (unmarried). Salary commencing at £100 a year, increasing to £200, with board, attendance, and washing. Applications to the Superintendent.

County Asylum, Rainhill, near Liverpool.—Assistant Medical Officer. Salary commences at £100, with an annual rise of £25 up to £200, with board, attendance, and washing. Full particulars of the Medical Superintendent.

Hospital for Women, Soho Square, London.—Registrar. Honorarium 35 guineas. Full particulars of David Cannon, Secretary.

King's College, London.—Demonstratorship in the Bacteriological Laboratory. For conditions of appointment apply to Walter Smith, Secretary.

North London Hospital for Consumption, Hampstead.—Resident Medical Officer. Honorarium £40 per annum, with board, lodging, &c., in the hospital. Applications to the Secretary before Jan. 6th at 41 Fitzroy Square.

Owens College, Manchester.—Junior Demonstratorship in Physiology and Histology. Salary £100. Applications before January 4th to the Registrar, who will furnish further information.

Poplar Hospital for Accidents, Blackwall.—Resident Assistant House Surgeon. Salary £80 per annum, with board and lodging. Applications to the Secretary before Jan 8th.

University of London.—The Registrarship.—Candidates for the appointment must send in their applications not later than Jan. 25th. Salary commences at £300, and rises by annual increments to £1,000 per annum. Further information may be obtained of Arthur Milman, M.A., LL.D., Registrar, University of London, Burlington Gardens, W.

Victoria Hospital for Sick Children, Chelsea.—House Surgeon. Salary £50 per annum, with board and lodging. There is also a vacancy for House Physician on same terms. Applications before Jan. 11th to the Secretary at the hospital.

Appointments

CAMERON, R. D., L.R.C.P., L.R.C.S., Edin., Medical Officer for the Walsington Sanitary District of the Howden Union.

CHESTWOOD-AIKIN, K.C., M.B. Aberd., House Surgeon to the Central London Ophthalmic Hospital.

CHRISTON, H., M.B., B.S., Durh., Resident House Surgeon to the Ingham Infirmary, South Shields.

COOK, W. H., M.D. Brux., M.R.C.S., L.R.C.P., L.S.A., Resident Medical Officer to the Royal United Hospital, Bath.

CROSS, E. J., L.R.C.P., Lond., M.R.C.S., D.P.H., Camb. Medical Officer for the Second Sanitary District of the St. Neots Union.

DAWAR, T. F., M.D., Aberd., C.M., B.Sc. (Pub. Health), Medical Officer for the Burgh of Monifieth, N.B.

ELLIOTT, THOS., M.D. Dub., L.M., L.R.C.S., Medical Officer for the No. 1 Sanitary District of the Tonbridge Union.

HAWORTH, J. J., L.R.C.P. Edin., L.R.C.S., L.F.P.S. Glasg. Medical Officer for the Filey Sanitary District of the Scarborough Union.

HUNTON, Fred., M.D., B.S. Durh., Medical Officer of Health for the Stockton Sanitary District and the Workhouse of the Stockton Union.

JONES, JAS. H., M.B., M.S. Edin., Medical Officer of Health for the Newport (Mon.) Port Sanitary Authority.

MILLER, WALTER, F., M.B., Durh., L.R.C.P., M.R.C.S., Medical Officer for the Alwinton Sanitary District of the Rothbury Union.

OLIVER, WILLIAM, M.B., M.S. Edin., District Medical Officer for the Saddleworth Union.

PEPPER, H. M., M.R.C.S., L.R.C.P., Lond., Resident Assistant Medical Officer to the Royal Berkshire Hospital, Reading.

SMITH, RAGINALD, M.R.C.S., L.S.O.P., House Surgeon to the West Norfolk and Lynn Hospital, King's Lynn.

Births.

JOLLY—Dec. 25th, at Godstone House, Sydenham, the wife of S. Blake Jolly, M.B. Cantab., M.R.C.S., of a daughter.

Marriages.

BORRETT—STEWART.—On Dec. 19th, at All Saint's Baywater, George G. Borrett, Surgeon, Royal Navy, eldest son of the late Rev. George K. Borrett, of Hastings, to Grace Gwendoline Haldane, only child of the late James Stewart Powis Square, Baywater.

PILLING—TOPHAM.—Dec. 28th, at the Parish Church, Matlock, Charles Ernest Pilling, of Norwich, solicitor, son of the late Rev. J. R. Pilling, Rector of Wells, Norfolk, to Emma, daughter of Herbert Topham, M.R.C.S. Lond., of Tor House, Matlock B. & A.

Deaths.

CHIPPENDALE.—Dec. 23rd, John Chippendale, F.R.C.S., of Upper Phillimore Place, Kensington, aged 91.

FREHSEN.—Nov. 23, at Sea Point, Cape Colony, O. G. de Wet Fehrsen, M.D., only surviving son of Captain A. Fehrsen, H.M. 21st Light Dragoons, aged 80.

GROVE.—Christmas Eve, at St. Ives, Huntingdonshire, William Richard Grove, M.D., aged 57.

HARRIS.—Dec. 21st, at his residence, Trengweth, Redruth, Cornwall, Henry Harris, F.R.C.S., in the 86th year of his age.

KIDD.—Dec. 26th, at 38 Merrion Square, Dublin, George Hugh Kidd, M.D., Past President Royal College of Surgeons, Ireland, and Royal Irish Academy of Medicine, aged 71.

WILMOT.—Dec. 19th, at 8 Richmond Hill, Bath, Philip Mann Wilmot, M.D., aged 90.

NOTICE—Announcements of Births, Marriages, and Deaths in the families of Subscribers to this Journal are inserted free, and must reach the publishers not later than the Monday preceding publication.

Original Communications.

THE PHARMACOLOGICAL ACTION OF PURGATIVES.

By WILLIAM MURRELL, M.D., F.R.C.P.,

Lecturer on Pharmacology and Therapeutics at Westminster Hospital.

THERE is much difference of opinion respecting the mode of action of purgatives, and especially of the group—the latest addition to our list—which includes the natural aperient mineral waters.

One thing is perfectly clear, and that is that the majority of purgatives derived from the vegetable kingdom belong to the class of cutaneous irritants. The irritative effects of such drugs as croton oil, gamboge, and elaterium when applied to the skin is well known. Croton oil irritates the skin, not only when applied topically, but even when taken internally. Elaterium is such a powerful cutaneous irritant that people engaged in handling the drug suffer severely from ulceration of the nails and adjacent tissues. Colocynth, although less distinctly an irritant, produces persistent sneezing when inhaled, accompanied in the case of many people by attacks of dyspnoea resembling those of asthma. A similar condition results from inhaling powdered ipecacuanha, which is a common constituent of most of the ordinary aperient pills. This irritative effect leads, when the drug is taken internally, to increased peristaltic movement and to a rapid evacuation of the intestinal contents. The stimulation may be exerted on the mucous membrane itself or on the motor ganglia which preside over the contractions of the intestines. If it is irregular or intermittent it is apt to cause the patient much discomfort.

From a purely pharmacological point of view, any cutaneous irritants, with the exception of those which, by their general action produce symptoms of poisoning, might be employed as purgatives, provided only that they were not absorbed by the stomach and reached the intestines in safety.

Saline purgatives have an enormous advantage over purgatives of vegetable origin in not being irritants. It is probable that most of them act simply in virtue of their bitterness. The intensely bitter taste, both of sulphate of magnesium and of sulphate of sodium is well known, and is readily appreciated even in very dilute solutions. Bitters excite the secretions both of the stomach and of the intestines. Familiar examples are afforded by the action of such drugs as gentian, quassia, calumba, and angustura administered immediately before meals in improving the appetite and stimulating the powers of digestion. These drugs fail to act as purgatives for two reasons: first, because many of them contain astringent principles, and, secondly, because they are commonly taken in small doses mixed with sherry or gin, or some other form of alcohol which, by dilating the blood-vessels of the mucous membrane of the stomach, facilitates absorption.

Bucheim and other observers, both in France and in Germany, at one time maintained that the action of

saline purgatives was due solely to increased peristalsis, and even went so far as to suggest that the watery evacuation was the result, not of increased secretion from the intestinal mucous membrane, but was simply the fluid in which the salt was administered or with which it came in contact in the alimentary canal. This theory is now exploded. It is true that purgative salts do not produce catharsis when given in a concentrated form to animals fed for some days previously on absolutely dry food, but this is due not to the absence of water in the alimentary canal but to its deficiency in the blood.

Every clinical observer is aware of the fact that the natural purgative waters fail to exert their characteristic action when the patient is confined to bed, and from his recumbent position is less favourably placed for the passage of the fluid into the intestines than when he is following his ordinary avocations. It is also a common experience that in these cases the action of the aperient is materially assisted by massage of the abdomen, which facilitates the passage of the fluid through the pyloric orifice. At Carlsbad and other places, where aperient waters are drunk, the patient is instructed to walk so many hundred yards after each cup of the beverage, and this undoubtedly greatly assists the progress of the fluid down the intestinal tract.

There is no doubt that the effect exerted by bitter waters on the stomach is beneficial quite apart from the purgative action, and it is a common experience that patients whose breakfast ordinarily consists of a cup of tea and a piece of dry toast find that they can eat a good meal and digest it after a glass of Hunyadi Janos water sipped slowly whilst dressing.

With regard to the purgative effect the bitterness of the water is responsible for its excito-secretory action, whilst its low diffusibility impedes the re-absorption of the fluid. As a joint result of the stimulated secretion and the diminished absorption there is a largely increased accumulation of fluid in the intestinal tract, which partly from the effects of gravity and partly from a gentle stimulation of the peristaltic movement excited by distension reaches the rectum and produces a copious and comfortable evacuation.

Some saline purgatives affect the peristaltic movements so slightly that they are powerless to give the secreted fluid the necessary impetus downwards, the result being that there is a risk of re-absorption with the attendant dangers of griping and discomfort. It is rarely expedient to employ a single member of this group, it being found by experience that much better results are obtained by judicious combinations, such as occur in the natural purgative waters.

The mode of employment of an aperient water materially influences its action. In the case of Hunyadi Janos water, the member of this group which I most commonly prescribe, I direct the patient to dilute half a tumblerful with an equal quantity of boiling water, and to sip it slowly whilst dressing in the morning. The result is that there is one copious and easy evacuation immediately after breakfast, and no further trouble during the day. The dose can be regulated to a nicety, and it can be taken day after day and month after month without the slightest risk of exciting a catarrhal condition of the intestines.

Lectures

ON

THE DIAGNOSIS OF INSANITY.

By THEO. B. HYSLOP, M.D.,

Lecturer on Mental Diseases to St. Mary's Hospital Medical School,
Assistant Physician to Bethlem Royal Hospital.

LECTURE II.

In my first lecture I mentioned several sources of fallacy in our estimation of the influence of heredity. I now propose to treat somewhat more in detail those factors which are regarded as giving rise to morbid mental states in the life history of a family. The mental tendency or disposition to think, feel, or act in some particular way, is usually the result of a transmitted tendency gained by ancestral experience. This tendency is termed an "inherited disposition." A complete account of all the factors which form the data for a theory of development and heredity would include the facts of embryology, and this would also necessitate an account of the relationship between the more or less isolated germinal cells and the development of new individuals. It is not part of our object, however, to conjecture as to how the potentia activities of the germinal cells are derived. It must suffice to state that it appears highly probable that the germinal substance does contain certain specific characters which manifest themselves in the offspring.

Evolutionists assert that the psychical development of the individual is mainly conditioned by that of the race—i.e., owing to the principle of hereditary transmission, the nerve centres and the corresponding psychical activities tend to unfold in the individual in the order in which they have been developed in the history of the race. They also maintain that in the evolution or progressive development of the race any improvement of faculty or capability tends to transmit itself as a fundamental capacity or inherited disposition. In studying every case of mental disease it is essential that we take account of all the internal and external factors which tend to give rise to or favour the development of abnormal mentation. These factors may be grouped as follows:—

(1) *Internal.*

- (a) The variations or inequalities of the individual's original capacities.
- (b) The influence of heredity.

(2) *External.*

- (a) Variations in the social environment.
- (b) Variations in the physical environment.

Original capacities are not to be explained entirely as mere results of growth and adaptation to external surroundings. The physical organism does appear to possess certain fundamental capacities which predetermine its adaptability to external conditions, and as I have stated elsewhere, (a) mental development must start from some inherent state differing in character from any bodily state, and the operation of the mental causes and influences of the development is often only to be estimated by observing those mental laws, facilities, or prohibitions, which do not directly depend upon what we know of the physical successions. Mental development is undoubtedly dependent upon physical development in its ultimate aspects, and, arrest or interference with the latter will arrest or modify the former. Other things being equal, however, the mind possesses within itself certain fundamental attributes, which, so far as we know, cannot be explained in physiological terms, and which manifest themselves throughout the process of development apart from adaptive reactions of the physical organism to any environment. That

the mind itself really possesses fundamental intellectual functions of discrimination and assimilation, also primary capacities of feeling and willing, which manifest themselves out of all proportion to any apparent physical development, is evidenced over and over again in the moulding of genius. A full inquiry into the life histories of geniuses, and of some forms of abnormal mentation would apparently lead to the conclusions that ancestral experiences or acquisitions made in the life history of the race do not necessarily always enter into consideration as factors; nor do the conditionings of such mental developments invariably follow what we imagine to be the proper laws of organic and nervous development. It is also important to remember that these capabilities need not necessarily manifest themselves at the early periods of an individual's life; nor are they entirely dependent upon the environment which acts upon the mind through the nervous structures. An investigation of the original capacities of an insane patient not infrequently gives a clue to the whole nature of the case. Thus, for example, it is not uncommon to meet with an individual who at the period of puberty or of adolescence has broken down mentally, overwork being assigned as the cause. The friends inform you that, as a child, the patient was precocious and possessed a marvellous memory. This excessive physiological retentiveness has in reality been the leading factor in causing the breakdown. The parents, in their emulation at the possession of such an apparently intelligent child, have not only sanctioned, but even applauded, an undue amount of mental cramming, with the unfortunate result that the whole brain and mind have suddenly become a wreck. In the educational question there is no point of more importance than that of distinguishing between mental growth and development. Mind is said to grow when it increases its stock of materials; when it assimilates its materials, it develops. With abnormal growth, true development is apt to be impeded—e.g., in preparing for examinations the excessive growth of the bulk of retentions may, for a time, impede true mental development, just as an excessive amount of nutrition may produce fatness, while, at the same time, rendering the physiological activities more sluggish, i.e., with physical corpulence we have lessened bodily activity, and with mental agglomeration we have diminished power of thought. The possession of abnormal retentiveness of memory may serve to explain the early victories (as students) and later failures (as men) of numerous individuals. Many a so-called genius may be likened unto a well-ballasted barge, whose bulk of retention necessitates slowness of movement. In true genius there ought to be a just proportion between growth and development, otherwise the genius is apt to end in degeneration.

(b) *Inherited Dispositions.*—Much stress is laid upon the hereditary factors in insanity, but an imperfect conception as to what constitutes an hereditary predisposition gives rise to much inaccuracy and confusion. These causes of confusion I have already stated to be due either to a too narrow notion as to the neurotic factors in the ancestry, or, on the other hand, to a too wide notion which includes hereditary factors which, in reality are of little practical significance. The transmission of abnormal or diseased modes of thought is a subject which, in its theoretical aspects, is too wide for our consideration; we have merely to do with the data as we find them. In speaking of hereditary influences, we limit the influences to those which primarily affect the nervous system and are termed neuroses, and to such diseases as are intimately associated with neuroses or which affect the life history by developing a tendency to the production of neuroses.

During the five years 1889 to 1894, inclusive, the yearly average number of insane patients admitted to asylums in England and Wales was 8,058 males and 8,557 females. Hereditary influence was ascertained

to be present in 1,699 males and 2,171 females, or in the proportion of 21.1 and 25.4 per cent. respectively. Congenital defect was found in 470 males and 351 females, or in the proportion of 5.8 per cent. males and of 4.1 per cent. females (a). Of the 1,167 males and 281 female general paralytics, 186 males and 54 females (15.9 per cent. and 19.2 per cent. respectively) were found to have some hereditary influence. Of patients with suicidal propensity the yearly average was 1,818 and 2,433 females, and of these, 481 males (26.5 per cent.) and 734 females (30.2 per cent.) had a neurotic family history. These figures appear to demonstrate that heredity enters as a possible factor of causation in more than 20 per cent. of all cases of insanity, and, inasmuch as the hereditary factor sometimes considerably modifies the nature and course of the morbid mental state it is essential that this factor should be fully investigated and duly appreciated, otherwise our diagnosis is apt to be astray.

Speaking generally, the offspring tends to inherit the characteristics of both parents. In some instances, however, there may be a preponderance of the characteristics of one or other parent, or there may be a combination of some of the parents' qualities, which manifest themselves coincidentally or alternately during the lifetime of the offspring. Defect in the germ or sperm may result in abnormality of structure or energy, or both. As yet we know little of the conditions which render the germ and sperm suitable to each other. There are several practical points to be noted in the consideration of heredity. (1) An individual may develop or acquire a neurosis which affects his own life or the life history of his family. (2) The neurosis may increase or diminish in strength from generation to generation, or it may skip a generation. (3) The neurosis may appear at a later period of life in the offspring than in the ancestors. (4) The forms of the neurosis may alternate in the life history of the individual or in that of the family. (5) The type of neurosis may be determined by one or other parent with or without transmission of identical tendencies. (6) The inheritance of a slight neurosis connotes a ready breakdown but rapid recovery. (7) A strong neurotic tendency connotes either early and complete breakdown or perpetual instability. (8) An inherited neurosis often manifests itself as epilepsy, comparatively infrequently in general paralysis.

Some observers believe that general paralysis of the insane is not commonly attributable to a neurotic inheritance. This opinion is not confirmed by the statistics of England and Wales, although the proportion is somewhat less in general paralysis than in insanity generally. Revington believes that some cases point strongly to the theory that, while both hereditary and acquired neuroses, if strong, tend to the development of general paralysis at an early age, the tendency of the former is to protract, and that of the latter to shorten the duration of the disease. One fact is certain, namely, that the offspring of general paralytics are liable to suffer from all sorts of neuroses, and more especially epilepsy.

The other factors which tend to determine neuroses in the offspring are, phthisis, scrofula, gout, rheumatism, syphilis, alcohol, paralysis, spasmodic asthma, and diabetes. Undoubtedly, insanity, epilepsy, and other nervous disorders do occur in the offspring of phthisical persons, but whether it is comparatively more common for an insane inheritance to lead to phthisis, I am unable to say. The strumous diathesis is a most important factor in the production of idiocy and imbecility; gout and rheumatism are regarded as liable to start a neurotic diathesis. Syphilis is apt to predispose the offspring to the occurrence of minor nervous disorders, convulsions, epilepsy, and even insanity during childhood. Such children may be de-

fective intellectually and morally. Sometimes only these mental features are noticeable. In other cases, however, early blindness or deafness may lead to complete idiocy by deprivation of the senses. Epilepsy may lead to complete fatuity, or definite paralysis may result from local lesions in the brain structures. Some cases resemble general paralysis in their main symptoms inasmuch as there is progressive mental degeneration associated with the steady development of generalised paralysis with emaciation.

The consequences of alcoholism are not only impairment of the parents' own mental faculties but also in the offspring a tendency to drink, epilepsy, insanity, neuroses, idiocy or imbecility, and in a word, extinction of the race. From the social point of view, mortality is increased, births diminished, moral energies decreased, and development of intelligence retarded; in fact, weakness of the vital and intellectual energies of the race. A predisposition to alcoholism may be suspected under the following circumstances:— (a) When alcoholic symptoms appear too readily; (b) when there is a tendency to drink at an early age; (c) when the mental condition during drunkenness reveals the inheritance of ideas or tendencies which normally were kept in subjection; (d) when the mental symptoms are characterised by impulsiveness and the tendency to commit rash acts; (e) when delirium tremens, transitory mania, and even epileptiform convulsions manifest themselves with extreme readiness; (f) when, in addition to susceptibility to alcohol, mental perversions are caused suddenly by exciting agents other than alcohol; (g) when alcohol determines an inherited psychosis; (h) when the salient features of the case are misinterpretations of sensory impressions; (i) when the mental states or ideas are changeable and constantly interrupted by lucid intervals.

Some observers attach much importance to the existence of suicidal tendencies. Legrain gives four varieties of the special predisposition to suicide in these cases, viz., (1) Instead of having the form of genuine alcoholic suicide (an accidental act, or caused by fright in consequence of special hallucinations), the tendency is logically connected with the melancholic idea as expressed by the patient; (2) sometimes those who relapse in delirium tremens attempt suicide at each attack; (3) in the course of one and the same attack of delirium tremens, several attempts may be made; (4) in the ancestors of drinkers who become melancholiacs and commit suicide during an act of delirium tremens, a special predisposition to melancholia exists. It is of importance to remember that in a predisposed individual it is not uncommon to meet with maniacal conditions of an ambitious or an exalted kind. Delirium tremens occurring in such a predisposed person lasts longer and is more apt to be followed by another psychosis than in the case of one who has not the predisposition.

There are other functional and organic diseases of the nervous system which appear to be the result of ancestral taint, and which alternate or interchange in the life history of the individual or of the race. Briefly enumerated these are:—

1. Eccentricities, longings, cravings, morbid impulsive tendencies.
2. Suicide, crime, moral depravities.
3. Hysteria, trance, somnambulism.
4. Neuralgia, angina, megrim, tic douloureux.
5. Occupation spasms, stuttering, chorea, epilepsy.
6. Premature baldness, greyness, and senility.
7. Asthma, diabetes, goitre, deaf-mutism, paralyses.
8. Excitability, want of control, intemperance in love and religion.

Some inherited neurotic tendencies do not manifest themselves unless the individual is subjected to exciting causes. Such individuals are excitable, eccentric, very susceptible to shock, passionate, and easily affected by alcohol or by injury to the head. Others are readily

(a) Forty-ninth Report of the Commissioners in Lunacy.

affected by migraine, neuralgia, headache, sensory epilepsy, spasmodic asthma, neurasthenia, phrenasthenia, and other neurotic manifestations. Most of the cases with a family history of diabetes are of the melancholic or hypochondriacal type, and this is especially apt to develop at the periods of adolescence or at the climacterium.

These preliminary data are essential to the just estimation of every case of insanity, and failure to appreciate the family relationships may result in complete failure in diagnosis. Moreover, it must not be forgotten that, although an insane person may suffer from a diseased brain which requires medical treatment, the diseased brain is not the only object for study. Insanity is a disorder of the individual; and, in order to grasp the full significance of the disorder, the individual must be studied not only physically but mentally, and this involves a far reaching estimate of all the sociological and environmental relations which tend to modify the development and experience of the individual.

Vienna Clinical Lecture.

MORBUS MÉNIÈREI.

By PROF. J. GRUBER,

Otological Clinic, Vienna University.

[FROM OUR AUSTRIAN CORRESPONDENT.]

GENTLEMEN,—From the recent interest excited by Frankl-Hochwart in this disease of Ménière it appears to me opportune to review the latest opinions expressed on the subject. A large number of specialists have devoted much time and attention to the differentiation of the disease with a view to more correctly diagnosing and forming a better prognosis of different cases coming under treatment. Since the time that Charcot propounded his test drug quinine for the disease, we have become clearly convinced that there is a Ménière disease pure and simple; but we have also a symptomatic disease with Ménière's phenomena possessing all the trias—vertigo, subjective hyper-sensation, and deafness, any one of which were considered to be the true symbol of Ménière's disease. We are now satisfied that these symptoms are associated with other morbid conditions of the ear. Aurists have therefore an important duty to perform in distinguishing between the diseases of Ménière's phenomena and genuine morbus Ménièrei, which is now acknowledged by all practical aurists. My own opinion is that a clear notion should be formed and the terms properly defined "Ménière's Phenomena" and "Morbus Ménièrei." This I conceive would better express the opinion of Ménière himself in locating the site of the disease. It is well known that his attention was directed towards this subject by the laboratory experiments of Flourens who discovered the symptoms after cutting the semi-circular canals in rabbits. The origin of the vertigo long lay in obscurity after this time from the doubts expressed in the phenomena. Ménière, at a later period, obtained the same phenomena when the middle ear was affected, which probably in a secondary manner affects the labyrinth. At a later period still it was proved that the same phenomena could be produced by disease in the external ear which even now cannot be impugned. From recent physiological examinations it has now been conclusively shown that any pressure on the ampullæ or semi-circular canals will produce this feeling of vertigo, which may be easily conducted from any morbid changes in the middle or outer ear. Our duty therefore in diagnosis seems clear. We must determine exactly in every case with such symptoms whether the morbid change is located in the ear itself; whether it is a labyrinth affection pure and

simple, or a disease following another; whether it is a morbid condition of the middle ear or complicated with a primary labyrinth affection. The latter portion of the diagnosis is now an easy matter for aurists, as the objective examination with our improved methods of diagnosis will soon determine with precision the possibility of the origin and the probable changes that have occurred. By careful examination of every case where the so-called Ménière's phenomena are present we are more able to locate the morbid changes in the auditory organ and designate the disease by the changes or complications to the primary disease.

Having now diagnosed a case of Ménière's disease, we have next to inquire in to the nature of the primary morbid change in the labyrinth; whether it has originated from hæmorrhage or, what I consider more common, a secretory exudative process. I am of opinion that hæmorrhage of the labyrinth is a very rare lesion in the production of Ménière's disease. I admit that we do meet with slight hæmic extravasations in the labyrinth after death, as everyone at the post-mortem table can convince himself. We also find in ampullæ, the cochlea, or the semi-circular canals, a sufficient amount of pigment to attract attention, which has been extravasated from the blood in the first place, but the most convincing fact that this foreign body is an innocent factor is the fact, that every individual so examined will have been found during life to have been perfectly free from vertigo, hyper-sensation, or deafness. Large extravasations, however, occur after severe accidents, such as fracture of the skull, or in cases where men are engaged in spaces under high atmospheric pressure, such as divers. A case of the latter came under my observation in the person of a worker who had been confined in a "caisson" for a short time and was suddenly attacked with Ménière's affection. Although he was confined to hospital for several months, and in spite of all our efforts, he was dismissed unrelieved.

I have next to dispose of the secretory and exudative processes which I consider the more common cause. It has been already noticed that the principal point of diagnosis turns on the different parts of the labyrinth, viz., the ampullæ, semi-circular canals, and the cochlea. Along with these different portions of the internal ear the adnexa of the labyrinth may be noted, such as communicating ducts which have recently been shown in anatomy to be of physiological interest. The recessus cotugni of the dura mater is a cistern or reservoir which is connected with the aqueductus vestibuli. I have taken the trouble on my own account to examine more than one hundred temporal bones to satisfy myself of the importance of this saccus cotugni, which has convinced me that it is a connection of the highest importance in this disease. In different subjects, according to nutrition and age, we find this saccus cotugni of different sizes and conditions. In some adults, when carefully examined, a small hole that might admit a hemp seed will be found in every case; in other bones the same recess will admit an ordinary-sized bean. Here is a preparation where the saccus cotugni is obliterated and the aqueductus connecting therewith is filled with a solid column of dura mater. In another preparation you will find the coverings of the sac soldered together as if some morbid change had taken place. In the aqueductus vestibuli we have great variations and anomalies. I have met with bones when macerated where no opening at the end of the canal could be found, and no reduction of the endolymph could take place.

From what has been said with respect to the adnexa of the labyrinth, we might easily picture to ourselves with out much strain of the imagination how the morbid changes could be brought about in the ampullæ and the semi-circular canals with the foregoing phenomena. If the flow of endolymph by the closure of the aqueductus vestibuli, is affected by the adhesions in the saccus

cotagni or the obliteration of Rüdinger's discharge canals of the saccus cotagni, an accumulation of endo-lymph will take place, causing a great amount of pressure and probably tearing of the finer structures with extravasations of blood which would produce all the phenomena necessary for morbus Ménière; this condition usually takes place after injury to the organ. Another form of considerable importance in the production of the disease may arise from a too liberal use of alcoholic drinks, giving rise to congestion and increased endo-lymph which may be denied easy discharge owing to the closure of the canals, and thus produce the same symptoms. We cannot, therefore, dispose of the subject without faithfully considering many of these contingencies that are probably active in Ménière's disease.

There is another condition in the form of inflammatory exudations which is now placed beyond doubt by the recent investigations of Voltolini that may be very fruitful in the production of the disease and which he has termed labyrinthitis. From the various hypotheses advanced, it may be easily understood that Ménière's phenomena will accompany different morbid changes in the auditory organ, but in the future we must recognise morbus Ménièrei as a primary labyrinthine morbid process having all the trias-vertigo, with fainting and vomiting, the subjective hyper-sensory hearing and difficulty of hearing or even deafness. The labyrinthitis may easily be distinguished from the other morbid processes producing Ménière's disease by the preceding or associating febrile condition. The apoplectic form may be further separated as the secretory category, while a remaining number of the cases will still be unable to be diagnosed during life and retain the name though the lesion may be hypothetical.

Transactions of Societies.

THE OBSTETRICAL SOCIETY OF LONDON.

MEETING HELD WEDNESDAY, JANUARY 1ST, 1896.

The President, Dr. CHAMPNEYS, F.R.C.P., in the Chair.

ON THE INFLUENCE OF THE REMOVAL OF THE OVARIES ON METABOLISM IN ITS BEARING ON OSTEO-MALACIA.

PROFESSOR CURATULA (Rome), represented by Dr. Griffiths, contributed a paper embodying the result of his researches in connection with the treatment of osteo-malacia by the removal of the ovaries. Proceeding on what he described as "the now ascertained fact," that patients suffering from osteo-malacia may be cured by castration, he had studied the changes which take place in the metabolism the healthy animal after castration, with the object of ascertaining the ultimate changes in the metabolic activity of respiration and the composition of the urine after castration. In the communication made by him, through Dr. Barbour, to the Edinburgh Obstetrical Society, it was stated that after removal of the ovaries the quantity of phosphoric anhydride excreted in the urine was greatly diminished, and this for a considerable time, while the quantity of nitrogen remained unaltered. The diminution of phosphates began about the seventh day and continued for three or four months. This he had attributed to a diminished oxidation of phosphorus existing as an organic compound in the tissues presumably combined with calcium and magnesium and stored in the bones. He supposed that the ovaries, like other glands of the animal economy according to the general doctrine of Brown-Séquard had some internal secretion thus pouring constantly into the blood a product of which the chemical composition was still unknown, capable of facilitating the oxidation of the phosphorylated organic substances which supply the material for forming the salts of the bones. On this assumption the removal of the ovaries would entail a larger retention of organic phosphorus, and consequently a greater accumulation of earthy salts in the form of phosphates until the skeleton finally resumed

its normal solidity. Experiments performed since that date had proved this hypothesis to be correct. In bitches in which after castration the excretion of phosphorus in the urine had considerably diminished, the subcutaneous injection of from 10 to 40 c.c. of ovarian-glycerine juice immediately increased the elimination of phosphorus. The injection of larger quantities of the ovarian juice was followed by an even more remarkable augmentation of phosphates. The same results were obtained in experiments on dogs. In support of the view that the sexual glands had a moderating influence on the development of the skeleton, he mentioned the fact that all giants reported on by anatomists had been found to have atrophied testicles, and, on the other hand, the eunuch-shorters at the Sixtine Chapel all possessed a remarkably well-developed skeleton. The experiments in respect of the metabolic activity of respiration were carried out on mice, using an ingenious apparatus invented by Prof. Luciani. He had found that the quantity of carbonic anhydride eliminated after the removal of the ovaries was diminished and this diminution might, he suggested assist them in explaining the abnormal accumulation of fat in the system, which always follows castration. It was probable, indeed, that a similar influence was exerted by the ovaries in respect of the oxidation of adipose substances. The question arose whether this diminution in the elimination of carbonic anhydride was due to the non-introduction into the blood of a secretive product capable of promoting the oxidation of fat, or whether it was due to the fact that after castration animals became comparatively quiet and calm. According to Petrone's theory osteo-malacia was due to a modification of the system caused by the *fermentum nitricum*. He had injected into dogs pure cultures of one of the micro-organisms proved by Winogradsky to bring about the nitrification of the soil, but, so far, with negative results.

Mr. BLAND SUTTON regretted that the details of the experiments alluded to by the author had not been given in greater detail, the more so, seeing that such investigations notoriously involved great technical difficulty. Judging from his own experience osteo-malacia was a very rare disease in this country. He pointed out that patients with osteo-malacia usually suffered excruciating pains, which he formerly believed to be due to pressure on the nerve roots brought about by changes in the vertebrae, but if, as was stated, these pains disappeared within a few hours of the injections, it was evident that this pressure could not be the cause of the pain. It had been stated that in castrated domestic animals the skeleton was bigger than usual, but he would point out that such animals had been attened for a special purpose, which might explain the extreme development of the bones. He had, moreover, noted that in animals kept in confinement, as in the Zoological Gardens, there was often very marked development of the skeleton, in fact, he had, on inspecting the skeletons of lions and tigers, been enabled to say at once that they had been kept in captivity simply from the size of the bones, yet, he remarked, one did not venture to castrate lions.

Dr. A. ROUTH suggested, in view of the relationship between hypertrophy or removal of the thyroid gland and special symptoms; between the supra-renals and Addison's disease; between the hypertrophied spleen and leucocythæmia; the pituitary gland and acromegaly, and so on, it was not at all improbable on the face of it that some similar influence might be exerted by the sexual glands.

Dr. GRIFFITH said there was one marked difference between osteo-malacia as observed in this country and the disease described by that name on the Continent, viz.: that while over here it was exclusively a disease of advanced life, on the Continent it occurred at a comparatively early age. He pointed out that examples of various degrees of osteo-malacia might be met with in the bones of the aged women who died in the infirmaries. He did not think that the ovaries could be credited with any share in the production of the disease in advanced life at any rate. He mentioned that in the museum of St. George's Hospital there was the skeleton of a young person of which the bones presented the characteristic changes of osteo-malacia, and there was a similar specimen at Cambridge. The disease, moreover, was one which occurred in man. He thought they ought to take a some-

what wider view of the question and not ascribe it simply to the influence of atrophy of the ovaries.

Mr. BLAND SUTTON explained that the changes in the bones of old people to which the last speaker had referred were purely senile. They were totally different from those of osteo-malacia, which was an acute affection occurring principally, if not exclusively, during the child-bearing period of women's life. He was, however, not prepared to deny that it might occur in man.

Dr. DUNCAN was inclined to think that the cases described as occurring in the young were really instances of pseudo osteo-malacia occurring in subjects whose bones had been deformed by rickets in early life.

THE EFFECTS OF LACTATION ON MENSTRUATION AND IMPREGNATION.

Dr. LEONARD RENFRY, referring to what he said was one of the most popular beliefs among married women, viz., that suckling prevents conception, explained that in order to ascertain the truth, or otherwise, of this belief, he had taken notes of several hundred cases, with the result of eliciting many interesting facts. The intimate connection between the function of the breast and that of the uterus was well-known. When the breasts were actively secreting, menstruation was commonly absent. As soon as the mother ceased to suckle, menstruation usually returned as before pregnancy. The breast function, moreover, had an admitted relation with the process of involution, sub-involution being frequently met with in mothers who did not suckle their children. Again, after miscarriage sub-involution was more frequently met with than after full-time labour, in the production of which non-lactation doubtless took a share. Suckling often gave rise to pain in the region of the uterus, due to uterine contraction, and, according to Galabin, suckling a child after pregnancy might lead to abortion. With regard to the condition of the uterine mucous membrane during suckling, amenorrhoea under the circumstances must, he urged, be due to anæmia, presumably associated with little or no growth. On the other hand, when menstruation was complete and regular during lactation the mucous membrane had probably undergone the changes associated with the catamenia under ordinary conditions. He had questioned a large number of women on the following points:—(1) Number of pregnancies, (2) number of children nursed, and for how long, (3) whether amenorrhoea during suckling, and how soon catamenia returned, (4) whether pregnancy commenced during suckling, (5) whether, when present, menstruation was regular or otherwise. He had collected the histories of about 900 lactations, from which he had drawn the following results:—Of the 900 lactations 502 were attended by amenorrhoea, while in 388 the menses returned in a more or less marked degree. It followed that 57 per cent. of the lactations were associated with complete amenorrhoea, and 43 per cent. with menstruation at some time during the period. Of the 388 menstrual cases 226 became pregnant during suckling (equal to three-fifths). In 245 of the 388 cases menstruation began within three months *post partum*, and continued regular, until, in the majority of instances, conception occurred, or, in others, until the weaning of the child. In the remaining 143 the menstruation was irregular. He suggested that the 245 should be called cases of "absolute regularity," and the 143 cases of "relative regularity," and "relative amenorrhoea." In 57 per cent. of the cases there was absolute amenorrhoea, and in 26 per cent. absolute regularity, that is to say, nearly twice as many women had amenorrhoea as had regular menstruation while suckling. Dealing with the figures in another way, he pointed out that in 503 lactation periods associated with absolute amenorrhoea, only 29 impregnations took place, while of 388 associated with more or less menstruation there occurred 226 menstruations, in percentages the proportion being as 6 to 60. The explanation of these facts would seem to be that in the menstruation cases the mucous membrane had grown to such an extent as to be a suitable nidus for the impregnated ovum and *vice versa*. As bearing on the association of amenorrhoea and non-impregnation, he mentioned that a woman often became pregnant on weaning her baby without having any catamenia at all. From the foregoing, he deduced the following conclusions:—(1) that of suckling women only 57

per cent. had absolute amenorrhoea; (2) that 43 per cent. menstruated more or less, including 26 per cent. who had "absolute regularity"; (3) that impregnation did not take place as readily during lactation as at other times, though this was not true to the extent generally supposed; (4) the chances of impregnation with absolute amenorrhoea during lactation was only 6 per cent.; (5) with menstruation during lactation the chances were 60 per cent.; (6) the more regular a woman during lactation the more likely was she to become pregnant; (7) in the woman who did not suckle at all the menses usually appeared some time during the first six weeks after delivery.

Dr. EDEN did not think the author had established the existence of a functional association between the mammary gland and the uterus. In any case the activity of the mammary gland did not seem to have had any marked effect on the menstruation, for the cases were pretty equally divided. Moreover, menstruation should not be looked upon as merely a function of the uterus, for it was now regarded as a function of the entire organism. He admitted that it was not easy to say why some women should menstruate during lactation and others not, but the suggestion as to the relative redevelopment of the uterine mucous membrane did not carry them much further seeing that this was always reproduced during the first two or three weeks after the confinement whether the mother suckled or not. He pointed out that menstruation and ovulation were no longer regarded as indispensable concomitants, and one might take place without the other. Nothing was known of the condition of the mucous membrane during amenorrhoea, and it was quite conceivable that the preliminary changes in the mucous membrane which were associated with normal menstruation might take place without the final effusion of blood.

Dr. McCANN said that the author had forestalled him, for he too had been carrying out researches on this subject. His conclusions in the main agreed with those obtained by the author. In respect of the theory that the mucous membrane of the uterus during the amenorrhoea of lactation was not developed, he pointed out that a certain proportion of such women did become pregnant. The majority of pregnancies during lactation occurred after the eighth month even if the mothers continued to suckle. Prolonged lactation, especially when the supply of milk continued to be abundant, favoured hyper-involution, and he had seen cases of lactation continued for upwards of two years, in which the supply of milk had not ceased even when the child was weaned and the menses had not returned. He had notes of three such cases. In one of them the uterus only measured between 1½ and 2 inches. He pointed out that a woman might menstruate regularly during one lactation and have amenorrhoea after the next. He had carefully excluded collateral sources of blood effusion during lactation, such as cervical erosion, &c. He did not believe that sub-involution could be brought about by non-suckling, and he thought that too much had been made of the relation between the mammary gland and the uterus.

Dr. BOXALL asked if there was any table appended to the paper bearing out the conclusion that "the more regular the woman during lactation, the more liable was she to become pregnant." In respect of the tendency to sub-involution after miscarriage it might be that the tendency was due to the same cause as determined the miscarriage.

Dr. LEWES said that in his experience, prolonged lactation not unfrequently gave rise to menorrhagia, even when the uterus was of normal size.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

MEETING HELD FRIDAY, DEC. 13TH.

The President Dr. GRIMSHAW, in the Chair.

EXHIBIT.

Dr. M. M'HUGH exhibited a young man with syringomyelia.

UNCOMMON SYMPTOMS IN TWO CASES OF THROAT DISEASE.

Dr. J. J. BURGESS said the first was a case of extremely acute tonsillitis, in which frequent hæmorrhage from the surface affected was the prominent symptom. This

resisted all haemostatic drugs, was independent of an abscess which was opened, and persisted for some days after the acute symptoms had disappeared, until, as he believes, exhaustion finally causes its cessation. The second was a case of spasm of the larynx. The patient was a young gentleman in apparent health, who, after he was suddenly seized with a choking fit, was believed by his parents to be dead. Artificial respiration brought him partly too, but on some brandy being poured down his throat an intense spasm came on and apparent asphyxia; the symptoms were so sudden that death was believed to have taken place. Artificial respiration was preferred by the parents to tracheotomy. After six hours' artificial respiration he came to, the rash of measles followed, and the patient made a rapid recovery.

Dr. JAMES LITTLE said he had seen some cases of which Dr. Burgess' paper reminded him strongly. He thought the fact should always be kept in mind, that very severe and anomalous symptoms sometimes occur when the exanthemata (scarlet fever and measles) are about to appear. He was sure he had seen cases of this nature in which it was impossible to make a diagnosis or to account for the violent symptoms which ushered in the illness until twenty-four hours or more had passed.

Mr. WHEELER believed that Dr. Burgess would find two cases similar to his mentioned in the now defunct *Medical Times and Gazette*. He was not sure of the date of the number containing the reports, but he believed it was one of the numbers of 1859 or 1860. As well as he could remember, one of the reports was by a Mr. Stanley. During the discussion on one of the cases a gentleman made the strange remark, that the plexus of veins external to the tonsils communicated with the internal jugular vein, and that the bleeding was from the lateral sinus. He thought bleeding in Dr. Burgess' case was from the ascending pharyngeal artery.

Dr. J. W. MOORE said they had all every reason to be grateful to Dr. Burgess for having saved a most valuable life by his untiring perseverance. Dr. Burgess had communicated to him the name of the patient, who was now a medical man in England, and an ornament to his profession.

Dr. W. J. SMITH believed that the explanation of the severe hæmorrhage was the division of the vertical arteries that run in the pharyngeal folds. Those vessels cannot contract as well as other arteries, hence the severity of the hæmorrhage. As to ergot for internal hæmorrhage, except that from the uterus, he considered the drug quite useless.

Dr. WOODS wished to ask Dr. Burgess if he were present at the actual time hæmorrhage took place in the first case. He considered that a vessel had been opened by an ulcerative process. He was not sure that it must have been necessarily an artery. Venous bleeding he thought was a much more serious matter than arterial bleeding. The artery can contract properly, and retreat in its sheath; but this was not the case with veins, at least not to the same extent. He could not infer from Dr. Burgess' paper that he applied any local remedy. His experience was that local remedies are the best; but this did not mean that the necessity of the position of the body, so as to calm the circulation, should be neglected. With regard to the second case, he, Dr. Woods, thought that tracheotomy might have been performed with much benefit.

Dr. BURGESS, in replying, thanked the Academy for the way his paper was received. In reply to Dr. Woods he said he was not present at the actual time of the occurrence of the hæmorrhage in the first case. He arrived just after it occurred. He did not see the bleeding points, and his difficulty had he used styptics was, where to apply them. With regard to the second case he admitted that tracheotomy was the proper course to be adopted.

A CASE OF SYRINGOMYELIA.

Dr. M. M'HUGH devoted a few introductory remarks to a brief account of the pathology and symptomatology of the affection. The term syringomyelia was now restricted to cavities produced in the cord by the liquefactive or cystic degeneration of a gliomatous neoplasm. The gliomatosis results from a proliferation of embryonic tissue remaining over in that part of the cord developmentally the weakest, viz., posterior grey commissure and its

vicinity. Schultze first pointed out the symptoms characteristic of the disease, and with an accumulated clinical experience it was now possible to diagnose cavities in the cord from the patient's symptoms with almost the same facility and accuracy as posterior sclerosis, in a case of locomotor ataxy. The patient (exhibited, a male, aged twenty-five years, and a native of County Mayo, presented the following symptoms, viz.: trophic lesions in the hands, consisting in loss of the terminal phalanx of each middle finger, with the cicatricial remains of cutaneous fissures, and transversely corrugated nails, also remarkable thickening of certain phalanges (cheiromegaly of Charcot). Muscular atrophy of the ulnar type was also present, well-marked in scapular muscles and trapezius, which showed fibrillation; Faradic contractility impaired; sensory dissociation, i.e., analgesia and thermo-anæsthesia, together with retention of tactile sensibility and the muscular sense, well-marked, with a wide symmetrical distribution. The patient also exhibited scoliosis, with convexity towards the right, and spastic symptoms in the lower extremities; very slight vaso-motor disturbances and no ataxia nor ocular derangements, nor visceral troubles. The author referred to the trophic lesions in the hands, painless whitlows with cheiromegaly, as similar to those found in Morvan's disease. The latter, however, was now considered to be only a type of syringomyelia, and the case exhibited was a true example of the disease, showing Morvan's symptom—sensory dissociation, the most remarkable feature of the disease, and difficult to explain. A study of the ascending degenerations in cases of syringomyelia continued with careful clinical records, would probably throw considerable light on centripetal conduction in the cord. Having referred to the other symptoms, the author drew attention to the remarkable symmetry in the symptoms. One might infer that there was a single symmetrically-placed cavity with a lateral wing, extending into each posterior cornu, and occupying the cervical and upper dorsal regions.

Dr. CRAIG remarked that the symptoms of the case were most classical from the fact that they occurred in a patient from twenty to twenty-five years of age; that dissociation symptoms were so well marked, that muscular atrophy attacked the upper extremity, causing weakness; that there was spastic paralysis of the lower limbs and curvature of the spine.

Dr. BOYD congratulated Dr. M'Hugh on having presented to the Academy a most typical example of this rare form of spinal disease. Dr. Boyd drew attention to the scoliosis which is so often a marked feature in atrophy of the muscles of the shoulder and back. In Dr. M'Hugh's case the dorso-lumbar curve principally involved the left side, in contradistinction to the usual right-sided scoliosis in the dorsal region of growing youths and children. The pathology of the disease touched on by Dr. M'Hugh would point to the involvement of the posterior commissures of grey matter, principally due to the dilatation of the central canal. Why, under such circumstances, ataxy did not show itself as a more frequent symptom in these cases was not easy to explain. Possibly the ataxic symptoms had often been overlooked in the earlier stages of the disease; and we know that they often disappear when the lateral columns become involved in association with the posterior columns in other affections of the spine.

Mr. SWANZY said Dr. M'Hugh told them that in this case there was no ocular symptoms, and no doubt Dr. M'Hugh had investigated the matter. He would like to know if there was contraction of the field of vision, because that is no uncommon symptom in syringomyelia. But whether the contraction belonged essentially to the disease or whether it was of a hysterical character and only grafted on the disease, was not easy to decide. Some observers had found a peculiar neuritis in this affection, but he (Mr. Swanzy) thought it was not of common occurrence and it was not present in Dr. M'Hugh's case.

Dr. M'HUGH, in reply, said that the fact which Dr. Boyd emphasised—namely, that the scoliosis was to the left and not to the right side, was remarkable. The patient's eyes were examined by Mr. O'Devaine of St. Vincent's Hospital.

The Section then adjourned.

SOCIETY OF ANÆSTHETISTS.

MEETING HELD THURSDAY, DECEMBER 19TH.

[The President, Mr. F. WOODHOUSE BRAINE, F.R.C.S.,
in the Chair.

A PRECISE AND SCIENTIFIC METHOD OF ADMINISTERING
CHLOROFORM AND ETHER.

DR. R. W. CARTER, of Weymouth, demonstrated methods of administering chloroform or ether which he claimed were at once precise and scientific. He said he had no pet fad which he desired to ventilate. He warned anæsthetists never to allow their thoughts to wander from their important undertaking, the administration of an anæsthetic in a light and frivolous spirit amounting to a criminal misdemeanour. He insisted on the claim of the anæsthetist to complete silence on the part of those present at the operation and he urged that the anæsthetist ought never to allow himself to be hurried. He preferred to have the patient in the position in which he was to undergo the operation in order to avoid subsequent changes of position. With the patient supine he preferred the head to be inclined to one side, making forward pressure on the mandible, taking care not to remove him too hastily from the operating table after the operation was over. He classified subjects into three groups: (1) those who took the anæsthetic freely but were a long time getting under, e.g., the stalwart and the free liver; (2) those who took it well, were soon under its influence, and could stand a good deal of it; (3) those who took it badly, and who showed danger signals even before the vapour was administered. This last condition was determined by a multitude of different causes. In administering chloroform he himself always used Krohne's Regulating Inhaler with Duncan and Flockhart's chloroform, and he would object to giving it in any other way unless constrained thereto. For ether he had used two inhalers, viz., Clover's, and the thermo-ether apparatus which bore his own name, using Salamon's ether. His reason for introducing yet another inhaler was that after using Clover's inhaler many hundreds of times he had been struck by certain drawbacks which it presented. His plan was to bring the anæsthesia up to Snow's third degree, and, if carried to the fourth, to relax it and bring it back to between the second and third and to maintain it there, occasionally removing the mouthpiece awhile for the purpose of having a general observation as to breathing, pupils, colour, condition of skin as to perspiration, and pulse. He left it to the operator to tell him when to desist, and he carefully avoided allowing his attention to be distracted from the inhaler. He pointed out that the quantity required to effect complete anæsthesia varied considerably in different subjects, but in a prolonged operation more of the anæsthetic was usually given during the first twenty minutes than afterwards, though this was not quite so apparent with chloroform as with ether. Little more than half the quantity of ether was required with the thermo-apparatus than with a Clover's inhaler. He referred to a series of twenty cases published in the *British Medical Journal* for December 16th, 1893, in which the air breathed never contained more than 1 per cent. of chloroform vapour, and to one case in particular, in which a boy who was under operation for fifty minutes did not consume more than seventy minims of chloroform. In twenty-eight other cases the proportion of chloroform had varied from 1.22 per cent. to 2.76 per cent. He commenced the administration with an infinitesimal dose, gradually increasing the dose up to, but never exceeding, from $\frac{1}{4}$ to 5 per cent. at any stage of the narcosis. He observed that these figures spoke for themselves, and opened out a wide field for reflection as to how far they were justified in giving such heroic doses as many gave. He cautioned them against ever holding the hand over the open end of the inhaler for the purpose of getting the patient more quickly under, adding that nothing was more likely to bring about a fatal result. He protested against the use of the term "open method," as applied to any other method than that involving the use of such an inhaler. He pointed out that an imperfect system might be fairly well conducted for a while in good hands, and, *per contra*, a good method might be badly carried out in bad hands. When anything went wrong with the method he had described, the fault could only be the administra-

tion of an overdose, certainly not of an underdose as had been suggested. He urged that the one method was the giving of an unmeasured quantity of a most potent drug, and the other was supplying what the anæsthetist considered to be sufficient and watching its effects. He asked how it could be possible for any one to give adequate instructions in the administration of anæsthetics by the old methods. It was necessary to calculate the temperature of the air, the density of the vapour, and the patient's face, all being conditions which materially affected the safety of the patient.

DR. DUDLEY BUXTON pointed out that the cases comprised in the tables published by the author all seemed to have been of comparatively short duration, cases, in fact, which did not appear to present any particular difficulty. He himself had used the Junker inhaler for ten years, and had every reason to be satisfied with it. He was quite convinced of its superiority to the rough and ready methods of administering chloroform with the towel or handkerchief. The fact that these methods of giving chloroform had been attended with a fair measure of success did not, however, warrant them in abtaining from using a reliable apparatus such as that described and demonstrated by the author. At the same time no apparatus for giving chloroform afforded absolute protection against accident, in support of which statement he instanced the fact that two deaths had taken place at the Samaritan Hospital with a Junker inhaler. As to the use of the feather as an indicator of the state of the respiration, he said this was a matter of opinion, but the other modifications spoke for themselves. He was glad to see that an old suggestion of his, to put an air-cushion between the facepiece and the patient's face, had at last been adopted. His experience of the apparatus for the administration of ether had been all in its favour, but he said all such apparatus were open to the objection that one could not crowd on the anæsthetic as one could wish under special circumstances. It was sometimes very desirable to give large quantities in order to abridge or avert the stage of excitement under ether. When these apparatus failed to prove satisfactory he said it was due to a want of experience. The fault was not with the apparatus, but with the administrator. He said that as a body, anæsthetists had no petty jealousies in the matter, their only object being to know the best method of administering the anæsthetic to complete narcosis without unpleasant or dangerous symptoms.

DR. CARTER said that there was a tendency for saliva to accumulate in the reservoir of the Clover apparatus, especially with the patient's head turned to one side.

MR. DAVIS wished to protest against the use of the feather in Junker's inhaler, seeing that the faintest breath of an expiring patient would be quite sufficient to lift it up; and, in fact, to protest against any mask whatever covering the face in the administration of chloroform, it being of paramount importance to watch the colour of the *acc* as well as the breathing.

MR. TOM BIRD said that Mr. Clover had used the principle over twenty years ago, and that he himself had used the same apparatus for the last twenty-two years, and preferred it to any other. "Pressing the bulb" at each inspiration of the patient was an old practice of economy. With regard to ether apparatus Mr. Clover always considered the free surface of ether the best for evaporation, and in that he agreed with him. Mr. Clover complained that ether came off too freely at first, but not sufficiently so when wanted, and this seemed to be the time when some "thermo" appliance might be useful. He agreed that sometimes one required a superfluity of the vapour for certain patients, and he doubted the possibility of regulating the supply of heat according to the necessity of the individual case. The temperature of an operating-room ought to be 65 degrees Fah. for ether exhibition. He pointed out that the Junker inhaler before it was used might contain between the ether surface and the exit pipe a pretty strong amount of vapour. He asked whether this amount was accounted for in the calculation of percentages which had been given them; it ought to be blown away or used very slowly, or it would be extremely unpleasant to the patient. Some years ago he had tried the same principle, in which air was blown through ether, using his own body to produce the necessary warmth, but after four successive administrations felt as if he

had swallowed a snowball. He referred to the face piece of Mr. Morgan, by which the expiration of the patient was passed round the ether for its evaporation, but, of course, everyone must be aware that the air breathed by patients was very shortly as cold as the ether itself. He had once collected for lecture purposes at Guy's over 40 inhalers used for these substances, since which time he believed that the number had been added to considerably. He said that a German review of 20 years ago (in one of their year-books) contained a list of over 90 works on chloroform and ether, so that administrators seemed to be moving, even if slowly. With two bottles on this system, one for 18 years, and the other for four and over, he had had no trouble or accident. He was constantly giving it to patients sitting upright in dental chairs, for 20 minutes at a time, and, as a rule, no longer time was required, and this without much subsequent annoyance to the patient. He gave gas before the chloroform because it shortened both the time required and the amount of the vapour. The intimate mixture of the two, gas and vapour, was the secret of the best anaesthesia. He also added that Junker's apparatus was first made by Mr. Krohne (the instrument maker) for bichloride of methylene. With Wolf's bottle chloroform was administered at Guy's many years before; the principle in both is the same.

Dr. LLOYD said his experience did not confirm what the author had said about the saliva getting into the ether reservoir of Clover's inhaler, though it was, he admitted, possible for the ether to get mixed with vapours condensed from the patient's breath.

Dr. STORMONT MURRAY said he always watched the respiration, and not the pulse. He himself often found it necessary to cover in the open end of the inhaler because too much air entered and the patient could not be got under. He said he liked Junker's inhaler, but he had found that if used for several administrations the chloroform was apt to freeze in the pipe and prevent the vapour entering the facepiece. He had remedied this to some extent by substituting a bone tube for the metal one usually employed. Referring to the two deaths with the Junker inhaler that had taken place at the Samaritan Hospital, he explained that the patients, in both instances, were in such a condition that in all probability, however the anaesthetic had been administered, the result would have been the same. One was a deformed woman with advanced kidney disease and a large abdominal malignant tumour, and at the autopsy she proved to have only one coronary artery. The other was the case of a patient suffering from ruptured extra-uterine gestation, who, as the result of several days' bleeding, was in a condition of extreme collapse.

Mr. TYRELL said he had used Junker's inhaler for chloroform for the past fifteen years, and had adopted all the various improvements by Buxton, Hewitt, Carter, Braine, Krohne, and others, and he was a strong advocate of its use, but he thought that teachers should also instruct in the administration of chloroform with the simplest possible apparatus. The country practitioner, who might have no occasion to use chloroform for a month, would find india-rubber apparatus quite hard and unusable when wanted in a hurry. A drop bottle and a flannel mask were always ready and in order; a single layer of flannel he considered far preferable to folds of lint, and he strongly advocated dropping the chloroform slowly on to the centre of the outside of the flannel mask, where the wet mark of the chloroform could always be seen. He did not agree that three minutes was a long time, but considered five or six minutes or even more should be employed in inducing anaesthesia. For ether he almost invariably used Clover's small inhaler, but occasions might arise when pumping air through ether in a Junker's apparatus was of great service. Such an occasion occurred to him recently, when a man who had broken his neck twelve months previously, and had during that time only breathed with his diaphragm, was anaesthetised by a Clover's ether inhaler while lying on his back; he was then turned over on his face for the purpose of performing laminectomy. Precautions were taken to keep off pressure from the thorax and abdomen, but in this position the respiration was shallow, and before the operation had proceeded far breathing suddenly ceased, and artificial respiration had to be resorted to. Breathing was soon re-established, the patient placed again on his face, and etherisation was continued with a Junker's

apparatus, the operation lasting forty minutes, without further respiratory embarrassment.

Dr. DUDLEY BUXTON recalled that many years ago he had used a foot bellows with the Junker inhaler in order to free one hand, and he added that this gave just as good control as with the hand bellows.

Mr. GARDINER asked how the percentages of vapour were calculated?

Dr. CARTER, in reply, said he did not think there could be any mistake as to the saliva finding its way into the reservoir of Clover's inhaler, for it formed a separate layer beneath the ether. He timed the moment of complete anaesthesia when the corneal reflex disappeared. The percentages were arrived at by comparing the amount of chloroform consumed with the respirations of the patient. That might not be mathematically correct, but it only professed to be an approximation. He added that Mr. Krohne made an inhaler which could be used with one hand only.

Mr. BIRD said the facepiece could be fixed on with a piece of tape, thus setting one hand free.

The meeting concluded with a cordial vote of thanks to the author for his paper, moved by Dr. SILK.

BRITISH ORTHOPÆDIC SOCIETY.

THE first Annual Meeting of this Society was held at the Royal Orthopædic Hospital, Oxford Street, on Wednesday, December 18th, 1895. Present: Mr. B. E. Brodhurst (in the chair), Messrs. Ewens, Moxey, Jackson, Clarke, Openshaw, D'Arcy Power, Reeves, Keetley, Sunderland, Little, and Luke Freer and Tubby (Hon. Secretaries), together with Messrs. Baker, Sayers, and Tomba, and Drs. Moulouguit (Amiens) and Calôt (Berch-sur-Mer) as visitors.

The Hon. Treasurer's and Hon. Secretaries' reports were read and adopted; in the latter, after speaking of the inauguration of the Society and the three successful meetings held, especially that at Liverpool, where the members had been most hospitably entertained by Mr. Robert Jones and the Liverpool members, the Hon. Secretaries expressed a hope that the Society would be enabled to publish its transactions annually in book-form.

Messrs. Keetley, Power, Reeves, and the Hon. Secretaries were elected as a sub-committee to deal with the latter subject.

Mr. Keetley was re-elected Treasurer, and Messrs. Openshaw, Brodhurst, and Rawlton were elected to fill vacancies on the Council. At the invitation of Mr. Luke Freer, the next ordinary meeting was decided to be held in Birmingham in May next.

An ordinary meeting was held immediately after the annual meeting.

Mr. REEVES and Mr. KEETLEY showed cases of congenital hip dislocation, the former demonstrating his instrument for extension.

In the discussion that followed, Messrs. BRODHURST and CALÔT took part, mainly dealing with operative interference in such cases.

MESSRS. BAKER and WALSHAM had on view some interesting cases of congenital absence of fibula.

Mr. BRODHURST showed a cast of a severe case of talipes equino-varus, and Mr. EWENS one of a case of severe talipes-calcaneo-valgus in an infant.

Mr. BAKER demonstrated the action of his wrench for talipes-equinus and varus.

The meeting terminated with a vote of thanks to the Committee of the Royal Orthopædic Hospital for the use of their board-room for the meeting.

France.

PARIS, Jan. 4, 1896.

INFANTILE VAGINITIS.

DR. MARX recommends the following treatment for vaginitis in children, which has given him the best results:—Practise vaginal injections morning and evening with

a soft catheter, to which is attached an elastic ball of the capacity of ten ounces. The liquid used for the injections is a solution of permanganate of potash (1—1,000). The catheter should be inserted as far as possible into the vagina, and the solution injected with a certain amount of pressure, so as to thoroughly wash out the cavity. About twenty ounces may be employed at each sitting. After the injection the vulva is washed with a warm solution of boric acid and renewed every three hours. A piece of cotton wool is placed between the labii to prevent friction in walking.

In rebellious cases the permanganate of potash can be replaced by a solution of nitrate of silver (1—500).

ACUTE GONORRHEA IN WOMEN.

According to M. Strassman vaginal injections should be forbidden in acute gonorrhœa as favouring the dissemination of gonococci and notably their penetration into the uterine cavity producing complications that might otherwise be avoided. The honourable professor distinguishes in woman two varieties of acute blenorragia. In the first, which is localised essentially in the vulva and the urethra, all injections should be absolutely proscribed. The treatment of these cases comprises rest in bed, a light alimentary régime, the employment of purgatives, and the internal use of balsams. Locally, a warm solution of sulphate of zinc is applied, and after each application a compress of vaseline and ichthylol as ointment (15 per cent.) The second variety commences by the neck of the uterus and manifests itself by a muco-purulent discharge as well as by an erosion of the os. In this case the vagina is gently swabbed out with a sublimate solution of 1-1000 and a plug of gauze steeped in a mixture of glycerine and iodoform (5 per cent.) placed *in situ*. It is only after a few days of the above treatment that injections might be proscribed.

TIC DOULOUREUX.

The treatment of this terrible affection, which Trousseau affirmed never to have seen get well, is so difficult that a description of the method practised by M. Gilles de la Jurette may not be out of place. This treatment is very simple, but none the less efficacious. It consists in giving progressive increasing and progressive decreasing doses of extract of opium, treatment recommended also by the late Dr. Charcot. The first day two pills of half a grain each are given, the following day three pills, and so on progressively until four grains and a half are reached, which is the maximum dose. Little by little the pain diminishes in intensity, the attacks do not last so long, and the intervals between them are of greater duration, and, finally, the attacks cease altogether.

It is a remarkable fact that the patients show an extraordinary tolerance for opium. M. de la Jourette says he never saw a case of poisoning from the maximum doses, not even somnolence. The only drawback is the obstinate constipation that the treatment provokes.

Once the attacks cease, the patient is allowed to rest for a few days, after which the progressive decreasing doses are given.

THE MEDICAL PROFESSION IN FRANCE.

According to the report presented by M. Brouardel to the Paris Academy, the number of students registered at the Paris Faculty, is 6,000.

Of this total, 1,046 are foreigners; 879 men and 167 women.

In the last session there were 8,238 examinations, of which, 1,394 were adjourned.

The number of students in the Provincial Faculties number in the aggregate, 4,000, representing thus a grand total of 10,000 medical students.

The number of fully qualified men in the whole of France is from 13,000 to 14,000. In five years they will be nearly doubled.

[FROM OUR OWN CORRESPONDENT.]

Vienna, Jan. 3rd, 1896.

EXPERIMENTAL DIABETES.

At the Gesellschaft der Aerzte Biedl gave a short *resumé* of his experiments in connection with diabetes. His first effort was to produce a diuresis by means of grape sugar. In the case of animals he injected grape sugar into the bowel, and after a short time found sugar in the urine taken from the ureters. The same experiment was performed on the human subject, but the results were negative. Three litres of a ten per cent. solution were applied without any success. Needless to say that alimentary glycosuria in man met with the same result. He next injected the solution into the venous system; 200 to 300 cc. m. of a ten per cent. solution were injected into a vein of the arm, but the expected polyuria failed to appear, as the daily amount for three days after was unchanged. Neither could sugar be found in the urine, although Trömmer's test showed a reaction indicating the presence of other substances.

These results lead us to two conclusions. The absence of the polyuria tends to show that the sugar is not an irritant on the human kidney, as the secretion is in no way increased; or we may conclude that the sugar is so rapidly altered that it has lost all specific action in producing any acute hyperæmia of the kidneys. The first supposition is the more probable, as the constant coincidence of glycosuria with polyuria in diabetes makes it likely in the human subject that the elimination of sugar by the kidneys increases the urine. With the object of more closely investigating this hypothesis two patients were selected, into whom sugar solution was injected, and in order to obtain the urinary secretion direct from the kidneys the ureters were catheterised. It was found that the rapidity of the secretion increased within the first ten minutes from 6 or 8 drops to 24 or 40 drops, but both kidneys were not equally affected, sometimes alternating in the flow. In other two cases shortly after the injection a rigor was experienced and the temperature rose to 38.9° or 102° Fahr., but suddenly fell without any apparent cause as it could not be termed a septic fever although some experimenters have applied the term *æseptic*. It is now twenty years ago since Albert and Stricker observed these rigors in animals in the operation of transfusion, they also produced it by taking the blood stream of an artery and directly connecting it with a vein in the same animal. Domenices has more recently demonstrated the same phenomenon in transfusion into dogs.

As observed above there was a peculiar change in the

urine, a positive reaction could be obtained by Trömmér's test after long boiling. With phenyl-hydrazin a peculiar pointed crystal could not be identified with sugar was present. The fermentation test was negative, neither did polarisation show any change in the angle. The assertion that polyuria and glycosuria was absent must be qualified, for we find by these experiments that the urine taken immediately by the catheters were increased, and when examined contained from 0.5 to 2 per cent. of sugar, which would give a different result in twenty-four hours collection. It is generally understood that the polyuria is caused by the elimination of the sugar from the blood while circulating through the kidney. In our experiments it is probable that immediately after the injection the glycosuria existed for a very brief period, during which polyuria appears to have lasted.

Claude Bernard was the first to attempt the experiment of calculating the intensity of glykæmia of diabetes. He concluded that sugar was eliminated in the urine when the sugar in the blood reached 0.25 per cent. These figures were modified by subsequent investigators, although Claude Bernard's were confirmed in the dog, which led to the source of error. When 20 cc. of a 10 per cent. solution of sugar was injected in a dog the sugar rose in the blood to 6.8 per cent., 5.2 per cent., &c. In the human subject, however, it did not rise above 0.12, or 0.3 per cent. as the greatest injections. Frerichs records cases where he was able to raise the percentage in the blood to 0.6 and 0.7 per cent. after extraordinary quantities of sugar had been administered. In twenty-four hours after no sugar in the blood could be detected. Whether the sugar is transformed in the human blood or is rapidly burnt up in the muscles, when it is thus injected, no definite proof is yet forthcoming. This peculiar condition of the urine after injection still awaits explanation. Facts point to the blood being the first point saturated before glycosuria occurs, but what change in the organism prior to this is necessary has yet to be determined.

The Operating Theatres.

ROYAL FREE HOSPITAL.

ABDOMINAL SECTION AFTER RAILWAY INJURY.—RUPTURE OF KIDNEY.—NEPHRECTOMY.—Mr. BATTLE operated on a young man, æt. about 30, who had been brought to the hospital from King's Cross, having been found lying on the line after the passage of a train. He was suffering a good deal from shock, and complained of injury to his right shoulder, also pain in the abdomen. Examination revealed comminuted fracture of the right humerus in its upper third and a rupture of the pectoralis major muscle. The abdomen was tender, and respiration chiefly thoracic. A catheter was passed, and a few ounces of urine drawn off; this was clear at first, but later became deeply tinged with blood. It was noticed that dulness on percussion was present in the lower abdomen. About an hour later, when Mr. Battle arrived, the patient was still suffering from shock, and complained very much of pain in the abdomen, chiefly referred to a point below the umbilicus. He had vomited once or twice. Dulness on percussion was found in the hypogastric region extending into the left flank, the patient being partly turned towards the left side, and this probably accounted for the difference in dulness on the two sides.

It was evident from what the house surgeon said that the fluid which this dulness evidenced was increasing rapidly, and the duration of time which had elapsed since the accident made it certain that it was blood free in the peritoneal cavity. The condition of the man was evidently very bad and unfitted for a prolonged operation, but it was also evident that he would not be improved if the hæmorrhage went on unchecked. The patient was anxious to have something done, and as Mr. Battle thought his symptoms were due to a ruptured kidney, with laceration of the overlying peritoneum, thus permitting the blood to escape into the peritoneal cavity, abdominal section was performed. The abdominal wall was muscular and well developed, and the subperitoneal fat thick. The peritoneum bulged slightly, and was of a blackish tint, due to the presence of blood behind it. When this last was incised the intestine was immediately underneath it, and the quantity of blood appeared small, but when the intestine had been moved upwards the pelvis was found full of blood, which ran out of the wound in a thick stream. The region of the left kidney on the side supposed to be damaged was rapidly explored but no tear in the peritoneum could be felt, neither could the kidney be localised; the splenic region appeared normal, the right kidney appeared to be uninjured. On passing the hand upwards towards the spleen a second time the fingers became entangled with some streddy bands, the exact nature of which could not be immediately ascertained, and entered a cavity in which a body very like the spleen could be grasped; this was clearly the kidney separated from its bed and considerably lacerated; the capsule was still attached to the surrounding structures in the lower part. The wound had to be considerably enlarged before the kidney could be brought within reach; a ligature of strong silk was then tied round the renal vessels and ureter and the kidney removed. It was not possible to do anything towards closing the laceration through which the kidney had been drawn; the peritoneum was rapidly sponged and the wound in the abdomen closed. During the operation saline infusion (3j to the pint) to the extent of seven pints was given into the left internal saphena vein with considerable advantage to the patient, whose pulse became steadier and more full. No attempt was made to measure the quantity of blood in the peritoneal cavity, but there must have been several pints. The case, Mr. Battle said, was very interesting because it was very seldom that such a severe injury to the kidney was seen; as a rule, when the kidney was ruptured the only sign was hæmorrhage in the bladder, and possibly some effusion of blood round the kidney, but behind the peritoneum. Hæmorrhage into the peritoneal cavity from a ruptured kidney could only take place after laceration of the overlying peritoneum. Mr. Battle had never seen such a large amount of blood in the peritoneal cavity, excepting after severe rupture of liver or spleen, but considered the kidney the most likely source for the blood in this patient, because it had undoubtedly been ruptured as evidenced by the blood in the urine, and stress of the injury had been felt below the level of the two organs just mentioned.

REMOVAL OF LARGE MOLLUSCUM FIBROSUM FROM THE THIGH.—The same surgeon operated on a very large plicated tumour of a fibro-cellular character in a young girl, æt. about 21. It consisted of a pigmented brown plicated mass extending from the right buttock down the outer side of the thigh and across the middle of the thigh

to the inner side. The width at its base varied from about three to five or six inches, and when the patient stood up the folds reached almost to the knee-joint. There was a faint band of a brownish pigmentation extending into the healthy skin round the tumour. On the body the patient had many brown spots and one small molluscum fibrosum. She wished to get rid of the tumour which she had had since the age of 4, as it was inconvenient and caused her some pain. The incision required was a long one, probably about 20 inches, but the whole growth was removed down to the deep fascia, and it was found possible to bring the two edges of the skin together by means of interrupted sutures. A curious series of structures was met with in the deeper parts of the tumour, the nature of which will be investigated. Several beaded irregular bodies of whitish appearance, like a chain of beads of very irregular size, were removed, some with and some after the principal mass; they resembled more the condition spoken of by agriculturists as fingers and toes. On section these were solid, but presented no particular structure that was characteristic of new growth.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 8, 1896.

THE ROYAL COLLEGE OF SURGEONS,
ENGLAND.

THE half-yearly meeting of the Fellows of the Royal College of Surgeons, England, which was held on the

2nd instant, was in several respects a most important one. The agenda paper, to begin with, contained notices of motion relative to questions of such a contentious nature that it was only to have been expected that the discussions thereon would be animated and well sustained. In truth a great deal of interest throughout the proceedings was evinced by those present, both on account of the important issues involved, as well as by reason of the diversity of opinions expressed by the various speakers. Again, the meeting was in one respect at least an epoch-making one, inasmuch as it passed a resolution so strongly in favour of the claims of the Members to a share in the government of the College, that it may be safely asserted that nothing of the kind has ever taken place before. This point is especially worthy of note, for it shows in an unmistakably practical form how time has brought about among the Fellows a feeling favourable to the Members and their claims. A few years ago any such resolution as that which was almost unanimously passed by the Fellows last week would have been contemptuously cast aside. We may here point out that the resolution in question was as follows:—"That it is desirable to give to the Members of the College direct representation upon the Council." Practically, this means that the Fellows are now willing to share with the Members the privilege, hitherto enjoyed by the Fellows alone, of electing the governing body of the College. The precise manner in which the privilege should be exercised by the Members, in electing some of their own body to the Council, is merely a question of detail, which can be easily discussed at the proper moment. It was felt that the first step to be taken was to recommend to the Council that Members of the College should be directly represented on that body; this was quite enough as a commencement in this particular measure of reform. To have rendered the resolution more explicit at the present moment was certainly unnecessary and inexpedient. As the matter now stands, the Council have a definite recommendation to consider, which has been narrowed down to one question, and it will be interesting to learn how they will deal with it when, in the ordinary course of things, it comes before them. The next matter of importance which was brought forward for discussion was a resolution to the effect, "That, in the opinion of the Fellows of this College, women should be admitted to the diplomas of the College." After an animated discussion, this was passed by 45 votes to 10, and thus the decision of the annual meeting of the Fellows and Members in November last was reversed. We are glad that the Fellows have arrived at this sensible conclusion. In this respect the Council and the Fellows are in accord, inasmuch as the former have already intimated to the memorialists of the Women's Medical School their willingness to admit women to the College examinations. When the question was discussed at the meeting in November last, many speakers based their objection to the admission of women to the examinations on the grounds that women were not fitted to become

medical practitioners. But this was a mere side issue, which had nothing to do with the case; the suitability or otherwise of women for medical work was not a matter which the meeting was called upon to decide, for the State has already pronounced that women may become medical practitioners if they feel so inclined. Under these circumstances, then, the duty of the College, as of all Corporations, is to undertake the examination of women. The State has expressed its approval of women being admitted to all medical examinations, and the College cannot therefore shirk its responsibility of carrying out the requirements of the State in this regard. Undeniably, the important feature of the case is that if the examinations for medical degrees and diplomas is not provided for women by the Corporation, the State will interfere and compel the latter to make the necessary provision. The curious point, however, is that in the event of the Council agreeing to the above resolution they will be prevented from carrying it out by reason of the adverse vote recently recorded by the Fellows of the Royal College of Physicians. Clearly, therefore, some steps should be taken to remedy this undesirable state of things. In our opinion it now becomes necessary for the Council to approach the College of Physicians and to represent to the latter the expediency of immediately reconsidering their position with regard to the women question. It was only by a majority of nine that the College of Physicians refused the application of the memorialists, and, bearing in mind the fact that this insignificant number is probably the only obstacle in the way of the women being admitted to the examinations of the conjoint board, it is obvious that pressure should be brought to bear upon the College of Physicians with a view to the question being reopened at an early date.

THE NEW FACTORY ACT.

ON the first day of January, 1896, the new Factory and Workshop Act, passed by the late Liberal Government, came into operation. Its general effect is to increase to a great extent, and in many ways, the safety of the workers. So far as sanitary precautions are concerned, Mr. Asquith's measure constitutes a considerable advance upon all previous enactments of a similar nature. First and foremost the great principle of the prevention of overcrowding in workplaces has at length been formally recognised by the legislature of this country. The Act provides that a factory or workshop shall be deemed overcrowded, so as to be injurious to the health of its inmates, if there be less than 250 cubic feet of space to each person during the hours of work, and of 400 cubic feet during overtime. At the same time, there is an important rider to the effect that the Secretary of State may modify this proportion for any period during which other than electric light is used, and may as regards any particular manufacturing process or handicraft substitute any higher cubical figures than those mentioned. The necessity for such a proviso in many trades—such as baking—will be at once evident

to all who are familiar with industrial processes. Then we find that the powers of the administrative authorities are greatly increased. Thus, a court of summary jurisdiction, meaning, in London, a police court, may on complaint by an inspector, and on being satisfied that a factory or workshop is in a dangerous or insanitary condition, prohibit the place from being used until such works as are necessary to remove the danger have been executed. This provision will strengthen the hands of the factory inspector to an almost incalculable extent. Adequate penalties are provided for the employment of persons in places injurious to health, or for allowing wearing apparel to be made up, cleaned or repaired in places where there is scarlet-fever or small-pox. The last clause is so directly practical, so obvious, and so elementary as a common-sense first step in prevention of the spread of infectious disease, that the only wonder is why it was not placed on the Statute Book a generation ago. Further important provisions are made in the case of death from accident in a factory or workshop. Notice of occurrences must be given and a full register of them kept by the owner or occupier. A factory inspector must also attend the subsequent inquest, and the Home Secretary is furnished with powers for additional investigation should he think fit. Another most salutary feature of the new Bill is that laundries carried on by way of trade, or for purpose of gain, are brought under the control of the Factory Act. In steam laundries fans must be provided to regulate the temperature of ironing rooms and to carry off the steam of wash-houses; stoves are to be separated from workrooms; the use of gas-irons emitting noxious fumes is forbidden; and floors are to be kept in good condition and properly drained. These improved conditions cannot fail to confer an immense boon upon a hitherto neglected and oppressed class of workwomen. At the same time it is not a little curious that women engaged in this laborious and unhealthy trade are allowed to be employed for excessive hours of labour. The Act provides "that no woman shall work more than fourteen hours in any day, that the overtime shall not exceed two hours in any day, and that it shall not be worked more than three days in any week, or more than thirty days in any year." Another important point about the laundry clauses is the exception of "any such place where the only persons employed are inmates of any prison, reformatory, or industrial school; inmates of any institution conducted in good faith for religious or charitable purposes; or where the only persons employed are members of the same family, dwelling at the laundry; or in which not more than two persons dwelling elsewhere are employed." A number of provisions are made with a view to enforcing the duties of employers in the observance of sanitation, of the fencing of machinery, of the affixing of notices, and of the general carrying out of his responsibilities under the Act. In the case of tenement factories we note the practical point that the owner is made responsible in place of the occupier, who is often a man of straw. This Act is worthy of careful study by all who are

interested in the progress of preventive sanitary legislation. It must infallibly constitute a notable landmark in the history of the subject as a strenuous effort to solve a complicated and highly important social problem.

LACTATION AND PREGNANCY.

It is a matter of common belief that women are less liable to become pregnant *de novo* when suckling than under ordinary circumstances, but, curiously enough, no methodical investigation of the truth or otherwise of this tradition seems to have been made until recently, and last week Dr. Renfry brought the results of his inquiries before the Obstetrical Society, and reported by us in another column. The subject, however, is one of peculiar and practical interest to married people generally, and it is satisfactory to find that the belief is founded on fact to a much larger degree than is, perhaps, the case with sundry other old-wives' traditions. We are accustomed to look upon menstruation during lactation as a comparatively rare, or at any rate quite an exceptional, occurrence, but the author's figures show clearly enough that, as a matter of fact, nearly one half of suckling women menstruate more or less regularly during the lactation period, and in no less than 245 out of 900 the menses returned during the first three months after the confinement and continued regularly, unless, indeed, re-impregnation once more determined a temporary suspension. More to the point is the fact that of the 388 women in whom more or less menstruation took place during lactation, 226 became pregnant while still suckling. This special liability of menstruating lactifers to re-impregnation is brought out even more distinctly in the case of the women who menstruated with regularity during the lactation period. Looking at the figures in another aspect, we find that 57 per cent. of the women had absolute amenorrhœa during lactation, and only 26 per cent. regular menstruation, so that the amenorrhœic women were twice as numerous as those who menstruated with regularity; yet the proportion of pregnancies during lactation were ten times as numerous among the latter category as compared with the former. These figures place the comparative exemption of what we must consider as the normal suckling mother beyond question, though it considerably detracts from the accuracy of the popular belief if we consider suckling women as a class without regard to menstrual peculiarities. No plausible explanation seems to be forthcoming of the reason why some women menstruate during lactation and others not, and the obscurity which envelops this question is enhanced by the fact that a woman may menstruate more or less regularly during one lactation period and be amenorrhœic during the next. It is generally supposed that the mucous membrane lining the uterus is regenerated during the first two or three weeks following labour, but reliable observations are altogether wanting in respect of the condition of the mucous membrane in amenorrhœic as contrasted with menstruating suckling mothers. This considerably diminishes the value of the hypothesis

which seeks to explain the greater liability of the menstruating suckling mother to re-impregnation on the assumption of the more perfect regeneration of the uterine mucous membrane. Whether menstruation during lactation corresponds to a more advanced degree of reintegration of the membrane, such as would fit it to become the nidus for the fertilised ovum, is a matter of conjecture. We know that women may fall pregnant again without having had any return of menstruation, and it is quite conceivable that the uterine mucosa in such cases may have undergone the changes associated with normal menstruation short of the final effusion of blood. There is no doubt a somewhat intimate relationship between the mammary and uterine functions, but it is easy to exaggerate this influence. We have seen that it is certainly not absolute. Unduly prolonged lactation, on the other hand, has been known to produce hyper-involution of the uterus, with consequent arrest of the menstrual function, but in other cases it has appeared to determine menorrhagia, even with a uterus of normal size. It is stated that the tendency to subinvolution is greater in non-suckling mothers, and after miscarriages, than in suckling mothers after full-time labour, but this is an ingenious suggestion which does not appear to have any solid substratum of fact to support it. The subject is an interesting one, and some credit is due to the author for having, at considerable pains, placed the matter on a scientific basis.

Notes on Current Topics.

Newspapers as the Medium for Obscenity.

We have much satisfaction in announcing to our readers that the person calling himself "F. D'Aubey," who was committed for trial to the Gloucester Quarter Sessions for issuing grossly indecent circulars, was convicted on the 1st instant, and sentenced to six months' imprisonment, the chairman at the time remarking that "he considered the circular upon which the indictment rested one of the filthiest he had ever seen." In drawing the attention of the police authorities to this case, we felt that we were only discharging a public duty which the circumstances of the case imperatively demanded. It is certainly worthy of note, that within three weeks of the circular in question being placed in our hands the author of it should have been convicted and sentenced to six months' imprisonment. Great praise is due to the Medical Defence Association and the police authorities for having acted so promptly upon the information conveyed to them by THE MEDICAL PRESS AND CIRCULAR, and we trust that the summary punishment inflicted upon this man will go far towards deterring similar offenders from carrying on their disgusting business. Meanwhile we would again give expression to the regret which all must feel, that certain of the newspaper Press, especially the religious section, seem to be unable to resist the temptation of a few shillingsworth of advertisements, and, yielding to that temptation, are found willing to place the announcements of

traders in obscenity before their readers from day to day. As regards this particular case we can present a case in point. Some few years ago his nasty circulars were brought to our notice, and it was pointed out to us that they were advertised in two of the leading dailies. We at once communicated with the editors of those papers, stating, in plain language, the nature of the abominable traffic for which their columns were made the medium. Neither of the editors even acknowledged our communication, but one of them discontinued the advertisement, and the other serenely continued the announcement, and, for aught we know, continues it to this day. We venture to submit that there is a point at which a censorship of advertisements by the publisher of a newspaper becomes necessary, and that no such officer ought to be allowed to plead ignorance when accused of inserting an advertisement which on the face of it is suspicious. We really fail to see any material difference in culpability between the obscene quack who concocts and circulates dirty but profitable circulars and the publisher who aids him by knowingly publishing attractive invitations to purchase the said abominations.

What is the Dose of Sulphonal?

AN inquest was held last week in Kilburn which in several respects was remarkable. But perhaps the most noteworthy feature in the whole case was the number of medical men concerned in it. The wife of a medical practitioner became seriously ill from emphysema and cardiac failure. A medical friend was accordingly summoned to attend her; for the sleeplessness which was present he prescribed for the patient two powders of twenty-five grains each of sulphonal. Two days afterwards death occurred, and the two medical men in attendance, namely, the husband of the deceased and his friend, drew up a report of the facts of the case and submitted them to a third medical man, requesting him to decide what the precise form of the death certificate should be. The latter gave his decision that death "from anæmia and influenza" ought to be certified. This was accordingly done. But, meanwhile, the medical friend who had attended the case began to have some suspicions that the patient had died of some narcotic poison, and upon the strength of this conviction he communicated with the coroner, also a medical man. So an inquest was ordered and a post-mortem examination made. The result of the latter was definite enough; much organic disease was shown to be present in the various organs, and in view of the suspicions aroused, the contents of the stomach were saved, of which, however, it may here be remarked that nothing more has been heard. The evidence at the inquest was entirely confined to medical witnesses, and the *point de résistance* thereat was the question of the proper dose of sulphonal under the circumstances of the case. The husband admitted that he considered the doses, 25 grains, large ones. The report, however, before us does not state any details as to their administration. The opinion, moreover, of the medical man who made the *post-mortem* was apparently to the effect that these

doses were sufficient to cause death, whereupon the jury returned a verdict of death from failure of the heart's action, and requested the coroner to censure the attending practitioner. The medical coroner immediately acted upon the instructions of the jury, and "severely censured" his *confrère* for prescribing so large a dose of sulphonal without first making a proper examination. Clearly, so far as the latter practitioner is concerned, it would have been better for himself if he had said nothing about having an inquiry. Moreover, as the inquiry has been closed without anything having been heard of the contents of the stomach, which were saved and forwarded to the police with a view to an analysis being made, it is conceivable that the object for which the inquest was ordered was not attained. Lastly, we cannot agree with the remark of the coroner that the doses of sulphonal were "large." The limits of the doses of this drug are 15 to 40 grains, but perhaps the coroner, as a medical man, meant that before any sulphonal was administered the attending practitioner should have made a close and careful examination of the patient's condition, which, according to the evidence, does not appear to have been done.

Who is to Blame?

THE disclosures made after the sanitary inspection of the St. Peter's Home, Woking, of the disgraceful condition of the drainage of the Institution, calls for something more than a passing notice. Here was a building designed by a modern architect on modern lines, with presumably every modern contrivance and advantage which it was possible to make use of for the perfect carrying out of the undertaking. Within ten years' time—that is to say last year—there was an outbreak of typhoid fever, and after the elimination of all other causes the source of the outbreak was directly traced to the drainage, which was found to be grossly defective. Imagine for one moment a modern institution, built at great expense, having the following defects in its sanitation:—"Defective valves in the water-closets; the drain ventilating pipes, running up the outside walls of the building, having serious leakages at the junction of the wrought-iron with the lead pipes; the lead soil pipes being received into the sockets of the earthenware drain pipes without any attempt at cementing, the former being four inches in size and the latter six inches; the drains not being laid in concrete, so that the ground and adjoining walls of the building were saturated with sewage; only one fresh air inlet to some three hundred yards of drain, the contrivance being merely an open grating, twelve feet and a half above the invert of the drain, and serving, as the stench from it proved, more as a vent for foul air than an inlet for fresh." What a hideous record of defects is this, as testified to by the experts who examined the building! The Medical Officer of Health of the district reports as follows:—"I desire to emphasise the lesson to be derived from this outbreak. Here we have a comparatively new and most expensively built Convalescent Home proving itself to be a veritable fever trap. It is quite obvious

that this serious epidemic arose from the very careless way in which modern principles of sanitation were carried out; and the result goes far to prove that neglect in carrying out such a modern system of drainage renders it as dangerous as the most ancient methods." Such are the facts, and it may well be asked, is there to be no sequel? How was it that the architect of the building permitted all these defects to be perpetrated? Who is responsible for the scandalous condition of things which has been revealed? The answer to these questions should be sought for by the authorities of the Home, who now find that in order to place the institution upon a proper sanitary basis, an expenditure of £2,000 will have to be incurred.

Bad Meat Traffic in Dublin.

ON December 18th a Dublin correspondent, writing under the signature "One Who Knows," made some extraordinary and startling statements as to the disposal of diseased meat in Dublin. He asserted that the carcasses of animals condemned by the veterinary inspector, and paid for by the Union, were systematically sold to two butchers, who re-sold them to middlemen, so that the meat ultimately reached the public in the form of "finest Irish beef." This abominable traffic, so our correspondent stated, has been carried on for years with the full knowledge of the boards of guardians, of the Public Health Committee of the Corporation, of the Veterinary Department at Dublin Castle, and of the Local Government Board. The matter advanced by our correspondent is of vital importance, and it seems hardly possible that one or other of the high official bodies named will fail to answer so serious a charge. The *Meat Trades Journal* quotes the letter in question, but appears to think it is little or no good to expect inquiry or explanation from official bodies, for it merely advises the Dublin victuallers to bear in mind the possibilities of the case. It is to be hoped that the subject will be thoroughly threshed out, and that a question will be asked in the House as soon as Parliament meets.

Professor Ray Lankester.

THE Lankester-Fraser fight referred to in our issue of the 18th ult., nearly ended in a fizzle. Much to the surprise of the backers of the Oxford Professor he exhibited a decided disinclination to come up to the scratch and put in a tardy appearance for the second round. The display of science and hard hitting of his northern opponent seem to have disconcerted him, and his letter of the 22nd ult., from the Athenæum Club—which seems destined to achieve notoriety—was a mere repetition of his former communication, and was certainly lacking in force. Possibly he may have relied on the support of Professor Calmette, but if so, his confidence was misplaced. Professor Lankester is nothing if he is not pugnacious, but to attack a man like Professor Fraser on a purely pharmacological question was the height of folly, and could lead to nothing but disaster. Professor Lankester has done some good work in the past, and we should be sorry if he were to disappear from the arena of practical politics, but

he should be cautious, and should not attempt to "bluff" people who are but little inclined to submit to the process. His latest escapade has done him no good and has not increased the confidence of his friends in his judgment. He has not done well in 1895, but with the onset of the new year, we trust that he will be more fortunate, and by sound scientific work, will do something worthy of his position as Linacre Professor of Comparative Anatomy in the University of Oxford.

Dr. Jameson.

FOR the second time within twelve months a medical man is attracting the attention of the whole civilised world by his military exploits. There is a considerable difference, however, between the defence of Chitral and the invasion of the Transvaal. In the one case the central figure has won the name of "hero," and in the other he has been freely stigmatised in the public press as "rebel" and "filibuster." It is to be sincerely hoped that Dr. Jameson will not be called upon to pay the extreme penalty which is affixed by civilised countries to the offence of leading an armed force into a peaceful territory. Dr. Jameson is a Scotchman by birth, and was educated at University College, London. He became a Member of the Royal College of Surgeons in 1875, Bachelor of Medicine and Surgery of London University in the same year, and graduated as doctor in 1877. Shortly afterwards he went out to Kimberley, where for many years he was the leading physician. He then formed the friendship of Mr. Cecil Rhodes, who came to him as a patient. He has been created a Companion of the Bath, and is the administrator for the British South Africa Company.

The Danger of Artificial Emaciation.

SOME people are born to be fat, just as others are born to be great, and it is not always desirable or even safe to fly in the face of Providence by seeking to diminish a single cubit of one's sectional dimensions. The principle to bear in mind is that everyone has his normal weight, though circumstances may determine a more or less temporary increase or diminution thereof. A departure from the normal in either direction is, *pro tanto*, incompatible with perfect health. This, of course, leaves in suspense the question as to what is one's normal weight, and those who are afflicted with what appears to the dispassionate observer to be a superfluity of adipose tissue usually resent the imputation that their obesity is other than an accidental and unavoidable circumstance. This point is easily settled by trying the effects of a carefully regulated but not over-strict regimen associated with daily exercise in the open air. All really superfluous tissue will disappear, although actual weight may not be palpably diminished, firm muscle taking the place of useless and burdensome fat. Obesity, however, is essentially a condition to be dealt with on an exclusively physiological basis. It is, of course, more or less amenable to medication, but the influence of drugs involves a brutal disturbance of the processes of nutrition, which cannot but be prejudicial to health.

This is particularly the case in respect of the employment of thyroid gland in extract, which, in effectual doses, often entails symptoms of a very disquieting and even serious nature. A sufficient number of cases have already been recorded to justify a note of warning, and it cannot be too strongly impressed upon practitioners that the thyroid treatment of obesity is one attended by a tangible amount of risk. In a German contemporary the case is recorded of a certain well-known dramatic artist, who sought to combat the opulence of form with which Nature had endowed him, and died in consequence. On ceasing to be obese—for the treatment was so far successful—he lost the placid temperament which previously characterised him, and became the prey of an unhappy irritability, consequent on an acute sensation of *malaise*; in short, he became nervous, impressible, and as unrecognisable from a moral as from a physical point of view. This story has a moral: Nature creates the fat and the lean, and wisdom lies in a voluntary adaptation to altered circumstances. For a fat man to “fly in the face of Providence” is a fact which ought to be discouraged, the more so as evidence is still wanting of the æsthetic superiority of the thin over the fat.

The Death of a Lion Tamer.

ANOTHER victim has been sacrificed on the vicious altar of sensationalism. On Christmas Eve a lion tamer was going through a performance at the Agricultural Hall, Islington, when one of the beasts in the cage tore a piece out of his arm and injured his spine. The unfortunate man was carried off to St. Bartholomew's Hospital, where he died six days later with symptoms reported as resembling hydrophobia. From evidence given at the inquest it appeared that deceased had been three years in the employ of the owners of the menagerie. The three lions in the cage at the time of the attack had been performing together for eighteen months, and not one of them had shown the slightest trace of temper. The simple report of this dreadful affair points its own moral. The repetition from time to time of these tragic deaths is nothing less than a scandal and a disgrace to our boasted nineteenth century civilisation. Why does not some humane member of Parliament take up the subject and introduce a short bill throwing the whole responsibility on the employers of the unfortunate “tamers”? It would be interesting to learn the exact nature of the fatal illness, and whether any bacteriological investigation was made at St. Bartholomew's.

The “Commission” of a Hospital Secretary.

A LARGELY attended meeting of the Governors and the Committee of the Great Northern Central Hospital was held in London last week. Its object was “to consider the question of secret commission and other emoluments paid to the late secretary, and the improper dealing with the same in the balance sheets of ten annual reports from 1885 to 1894.” An official statement showed that the salary and emoluments of the late secretary were in 1886, £499; in 1887, £899; in 1888, £593; in 1889, £980; in 1890, £805; in 1891,

£551; in 1892, £583; in 1893, £1,011; in 1894, £521; equal to an average of £750 per annum. The chairman, Mr. Murdoch, M.P., explained that at the time of the late secretary's election, at a salary of £300, the hospital contained only thirty-two beds. An able man was required for the development of the institution. The first arrangement was that the secretary should be paid 7½ per cent. on such legacies and donations as he influenced. This was afterwards reduced to 2½ per cent. The meeting finally expressed its confidence in the committee, and its satisfaction that steps had been taken to prevent a recurrence of such a state of affairs in the future. Many who are conversant with hospital matters altogether doubt whether a secretary should be paid any commission on receipts, and certainly very few persons would attempt to defend the practice in the case of legacies. It is desirable that the charitable public should be placed in the full possession of facts regarding the salaries of other secretaries. At the meeting Mr. Murdoch stated that the average amount paid to their late secretary was exceeded by that paid to similar officials by other London hospitals.

Vivisection.

THE question of the prohibition of vivisection which, we know, excites certain people in our own country, has been submitted to the test of popular opinion in a country which governs itself upon communistic principles, and, which, therefore, might be expected to give expression to the popular feeling on the subject. A measure for the total prohibition of vivisection was submitted *ad referendum* to the population of the Canton of Schwyz in Switzerland with the result that 40,000 votes were given against such prohibition, and only 17,000 for it, while a proposal to allow the procedure for scientific purposes was carried by an equally conclusive majority. *Apropos* of this decision it may be noted that a company has recently been formed in Paris for the purpose of popularising the Pasteur inoculations. It proposes to erect a hospital in which the inoculation treatment will be made a speciality, and the capital necessary has been subscribed on the moment. It thus appears that all the braying of the anti-vivisection organisations in this country and elsewhere has been attended with no more substantial result than noise if, indeed, it has not had the effect of disgusting the public with such a melancholy exhibition.

The Registrarship of the General Medical Council in Ireland.

WE understand that Dr. Robert Lynn Heard, Registrar of the Irish Branch of the General Medical Council, has resigned that position, which he has held with great satisfaction to the Branch Council and to the profession since the death of Dr. Steele many years ago. Dr. Heard has taken this step, which he has contemplated for some time, in order that the Branch Council might be free to select a new man to undertake the labour and responsibility of the coming election of Direct Representative for Ireland. In our columns

to-day will be found the announcement that the election of his successor will take place on the 16th of this month, the choice being in the hands of the Irish members of the Council, Dr. William Moore, Sir John Banks, Dr. Haughton, Dr. Atthill, Sir Philip Smyly, and Dr. Charles Moore. The salary, we believe, is £200 a year. Dr. Heard has acquired universal esteem by the courteous and efficient discharge of his duties during the long period of his service.

The Operative Treatment of Traumatic Insanity.

THE question of the operative treatment of insanity of traumatic origin is an interesting one, although mental alienation due to injuries of the head is of somewhat infrequent occurrence. In 2,200 cases of insanity treated by Kiernan, 45 were of traumatic origin, while Hay records 61 as due to the same cause out of 2,500 cases, thus showing practically almost the same proportion. In an interesting discussion which recently took place at a meeting of the Mississippi Valley Medical Association, several speakers referred to cases under their care of traumatic insanity which had been operated on successfully. Dr. George Cale, of St. Louis, reported two cases, both of which made good recoveries after operation; one was that of a patient suffering from acute mania, the result of an injury. Dr. Frank, of Chicago, also mentioned an interesting case in which he trephined, removing a large piece of bone. The patient, after having been in a lunatic asylum for five years, made an excellent recovery and took up the thread of her life where it had been suddenly interrupted at the time of the receipt of the injury. A relapse, however, took place some time afterwards.

Modern Medicine on the Stage.

A FRENCH dramatic author, M. de Curel, has distinguished himself by writing a play with a plot turning on a most advanced modern method of surgical treatment. His hero is the discoverer of a new vaccine for cancer, and with this precious remedy he inoculates a young girl, who incontinently dies. How any sane mortal could choose such a repellant subject for dramatic treatment is beyond comprehension. Yet M. de Curel is a shining light of the Theatre Libre, and is regarded by many competent critics as one of the most promising of the younger French playwrights. It is to be hoped that in future he will seek for sensations in realism from other than medical sources. We are glad to learn that, although the play has been published, the author has not ventured to put it on the stage.

An Antidote for Erysipelas and Puerperal Fever.

DR MARMORECK, a young Austrian *savant*, working in the Pasteur Institute, claims to have discovered a serum which extinguishes the *streptococcus* and all diseases produced by that bacillus. Professor Chantemasse has given a full trial to the remedy, after it had been fully tested on animals, in the hospitals,

and states his belief that, by its means, the mortality from erysipelas will be reduced by three-fourths. He made, last week, a formal report to that effect to the Paris Municipal Council.

The New Year's Honours.

THE medical profession are represented in the list of New Year's Honours by Sir Joseph Fayrer, Dr. Willoughby Wade, Mr. Robert Martin Craven, and Dr. T. A. MacCullagh. Sir Joseph Fayrer receives a Baronetcy, a reward which very aptly follows his retirement from official life. Dr. Wade is the well known physician of Birmingham, and he has obtained the honour of knighthood. The same honour has been conferred upon Mr. Craven, a general practitioner in Hull, whose active work in connection with the Conservative party there has probably been the means of his gaining his distinction. Dr. James Acheson MacCullagh, who has also been made a knight, is an alumnus of Trinity College, Dublin, and has thrice been elected Mayor of Derry. He is Medical Officer of the City of Derry Dispensary District. We beg to offer to each of our *confères*, here named, our congratulations in respect to the honours to which severally they have attained.

Electrical Photography in Surgery.

THE news of a remarkable discovery in photography is reported from Vienna. Briefly, it consists in the discovery of a new conductor of light. Professor Routgen, the well-known professor of the Würzburg University, has succeeded in photographing metal weights shut up in a wooden box, without showing anything of the casing on his negative. He is also said to have photographed the bones of the hand, all the soft parts being invisible. He photographs by means of light of an exhausted Crooke's pipe, through which an inductive current is passed. The discovery appears to be so far that the rays in question penetrate wood and flesh, but not bone or metal. It is surmised that photographs of the kind mentioned may have a valuable practical application in the discovery and location both of fractures and of bullets. If this discovery be sustained it will certainly take a first place among the many marvels of this scientific age. Those of our readers who are versed in electrical research may have already heard of Professor Routgen's interesting researches.

London Death from Hydrophobia.

AN inquest was held last week on the body of a child at Bow. Deceased was bitten by a dog, and seven weeks later developed symptoms from which she died in a day or two at the Poplar Hospital. Before the coroner the private practitioner who had been in attendance on deceased, and the house physician at the hospital, swore that the child died from hydrophobia. Yet the police brought forward the evidence of a veterinary surgeon, named Shaw, stated to be an inspector of the Board of Agriculture, to the effect that the dog was not suffering from rabies. At the *post-mortem* a piece of rag was found in the stomach of the dog, a fact which affords strong corroborative

proof of madness. Mr. Shaw must indeed be a bold man if, in face of the medical evidence and his own post-mortem examination, he can maintain that the animal was not affected with hydrophobia. There could be only one positive test, namely, the bacteriological. Without such a trial, Mr. Shaw's testimony is without value. One is at a loss to know why the police should bring forward unscientific and worthless evidence of the kind. Again, what has the Board of Agriculture to do with the matter? If the police and Mr. Ritchie are relying on loose and unscientific assertions of this nature, they are likely to land the public into a pretty quandary of epidemic hydrophobia. The injection of an infusion of the animal's brain into a guinea pig or two, would have speedily settled the question as to the alleged madness of the dog beyond the possibility of doubt. Surely, the Local Government Board has laboratories and bacteriologists enough at command to settle a point of this kind off-hand. Can it be that the police wish to avoid the enforcing of the muzzling order? It is always open to the authorities if they cannot trust English scientific men to send the brain of the animal to be tested over to Paris for a report.

Carbolic Acid Poisoning.

SCARCELY a day passes but someone takes carbolic acid by mistake for a more innocuous beverage. In Scotland it is generally instead of the national drink, whiskey. A few weeks ago the death of a nurse in the Glasgow Royal Infirmary took place, where the victim had wished to take a dose of castor oil, but took carbolic acid instead, a strange commentary on her powers of taste and smell, to say nothing of the want of care displayed by the responsible official. On Friday last a seaman died from the same cause in Leith. A steamer came into Leith from Grangemouth where one of the sailors had bought a gill of whiskey, and put it in his locker. Not far from Leith he gave the victim a drink from a similar bottle to that in which the whiskey had been put, but which contained carbolic acid. The man died as he was being removed to Leith Hospital. It seems an extraordinary piece of carelessness to have carbolic acid in a similar bottle to that in which whiskey is generally sold in Scotland, and, in addition to keep them both in the same locker. Somehow or other, notwithstanding the number of accidents which are due to the careless usage of carbolic acid, the public do not seem to be able to grasp its dangerous qualities, or that a very small quantity may lead to fatal results. Unfortunately, such cases as that of the seaman can hardly be reached by the law, but in the first case if the castor oil and the acid were kept in similar bottles one of the elementary rules with regard to the dispensing of poisons must have been disregarded. Of that we have no knowledge.

The Development of the Compulsory Notification System.

A FURTHER extension of the pains and penalties attaching to the notification system was sneaked through the House of Commons last session, and the

law has become operative on the 1st of January. By the Factory and Workshop Act of 1895 every medical practitioner is bound, under a penalty of forty shillings fine, to notify to the Chief Factory Inspector at the Home Office, London, every case of lead, phosphorous, or arsenical poisoning which he "is called in to visit," and for that function he is to receive the customary half-a-crown fee. There is no department, as yet charged with the detection of syphilis and gonorrhœa, but we are awaiting the inevitable Bill, promoted by the sanitarian faddists, which will compel the unhappy practitioner to publish these diseases also or else go to gaol.

Hospital Accommodation in Leeds.

THE Leeds Corporation have been compelled to recognise the need of providing further hospital accommodation within their jurisdiction. The Local Government Board have just sanctioned the borrowing by the Corporation of sums of £51,500 and £11,000 for hospital purposes.

AMONG the successful candidates who recently passed the Intermediate Medical Examination, at the Medical Faculty in Lisbon, was the Queen of Portugal. The Queen has now been studying medicine for two years, has passed all the preliminary examinations, and intends to complete her course and fully qualify herself for the diploma of the Faculty.

THE Annual General Meeting of Subscribers to the British Medical Benevolent Fund will be held at the residence of the Treasurer, 84 Brook Street, London, on Tuesday, the 14th inst., at 4 p.m., the President, Sir James Paget, Bart., in the chair.

TYPHOID fever is again prevalent in the different barracks in Dublin. The bulk of the cases have occurred at Island Bridge Barracks. Boards of officers are inquiring into the causes of the outbreak.

THE will of Sir George Martin Holloway, co-proprietor of the celebrated pill business, was proved last week, the personalty being something over £66,000.

DR. SCANES SPICER has been appointed an Honorary Physician to the Royal Society of Musicians of Great Britain.

THE French Government have voted a sum of £400 towards the fund for erecting a statue in Paris to the memory of Pasteur.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

NURSE ACCIDENTALLY POISONED AT THE GLASGOW ROYAL INFIRMARY.—An occurrence of a most distressing nature, casting a gloom over the inmates of the Royal Infirmary, took place on Tuesday night, 31st December. Miss Shaw, a nurse in Dr. Clark's ward, feeling unwell, went to the medicine press and took what she thought

to be a dose of castor oil, instead of which, she swallowed carbolic acid in mistake. Shortly after, Nurse Shaw was noticed to stagger and inclined to fall. Assistance was at hand, and immediate remedies used, but unfortunately, the nurse expired within fifteen minutes after taking the fatal dose. Miss Shaw, who was a daughter of an English Bishop, had been connected with the infirmary for several years, was about 23 years of age, and a great and general favourite with all the officials of the institution. Her untimely death is made particularly sad by the fact that she was about to be married to a clergyman. This sad event suggests the following queries:—How is it, that a nurse, familiar with the odour of carbolic acid, which is used daily in a surgical ward, could possibly mistake it for castor oil? How is it she did not in the act of swallowing discover her mistake? Was it due to the fact of her suspending her inspiration at the time of swallowing? These are points which should be inquired into, and means adopted whereby such lamentable accidents may be effectually avoided in the future.

VICTORIA INFIRMARY, GLASGOW.—DEATH WHILE UNDER CHLOROFORM.—A girl, named Helen Watson, a domestic servant, died in the Victoria Infirmary on the 28th ult., where she had been admitted for the purpose of being operated on. The four resident surgeons were present at the operation, one of whom administered chloroform, while the others proceeded with the operation, but before its completion the patient died while under the anæsthetic. The police authorities in their report state that "the doctors are unanimous in the opinion that death would have ensued *within two hours*, whether the patient had been operated on or not."

CHEMISTRY IN SCHOOLS.—The Conjoint Examination Board of the Scottish Triple Qualification have resolved on a new and important departure. The Board has decided to recognise Blairlodge School, a public school after the English models, for the teaching of chemistry and physics. The school has well-equipped laboratories and competent teachers, and is the first Scottish school to be so recognised. It is a sign that schools are moving with the times, for not very long ago the teaching of these subjects in the best schools was simply a farce, and was almost entirely subordinated to the cramming of foreign languages.

THE ROYAL INFIRMARY BOARD, EDINBURGH.—Miss Stevenson's name was the only one put forward last week at the close of the time for nominations for the vacancy on the Board of the Infirmary, and although the actual election does not take place until this week, there is no doubt that she will be the first lady on the Board.

LUXATIO PENIS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—The recent publication of a case of "Luxatio Penis" has drawn a good deal of attention to this rare accident, and thinking the subject might interest your readers I take the liberty of summarising some of the recorded cases.

In THE MEDICAL PRESS for Nov. 5th, 1879, we have the testimony of Mr. David Wilson that "the penis (of the Tichborne Claimant) retracts in a most unusual degree, so that on one occasion when he passed water, which had been retained for some hours at my expressed wish, the penis was absolutely out of view, and nothing whatever of it could be seen but the orifice from which the stream issued. Yesterday I found the membrane more turgid, but I endeavoured to push it back towards the neck of the bladder with which it is continuous, and found it perfectly easy to push the whole member out of sight."

Ivanoff, whose name tells his nationality, in 1885 reported the case of the total disappearance of the penis of a patient, aged twenty-three years, who was a married man and father of a family. After prolonged manipulation the part was restored to its normal position; and as a

precautionary measure the patient attached a string to the member.

Lenior, in 1849, placed on record a case of congenital luxation; and in 1886 Dr. Raven reported the following remarkable case of spontaneous luxation: "A healthy, steady, single man, aged twenty-seven years, shortly after he had gone to bed one night felt a sensation of cold in the region of the penis. He was agitated to find that the organ, a fairly developed one, was rapidly shrinking, and was, he thought, finally disappearing." On the arrival of Dr. Raven he found that "the penis had almost disappeared, the glans being just perceptible under the pubic arch. The skin of the penis alone was visible, and looking as it does when the organ is buried in a hydrocele."

Baumgarten, of Buda-Pest, reported a case as following on the site of circumcision in which reduction of the luxation was effected until the child was eight years old. This case in many respects resembles Lenior's.

Malinowski reports a case of Professor Levshin's, of Kazan. The trousers of the patient were drawn between a horizontal and a vertical cog-wheel of a mill; the skin of the scrotum and penis got torn, and the penis was dislocated under the pubic arch.

Cases have been recorded by Moldenhaur, Nélaton, Petersen, and Wagner, and Dr. Richard Neale in the third edition of his invaluable "Digest" gives references to three cases of luxation, and includes the cases of Ivanoff and Raven under the title of "vanishing," a name which is applied to a similar condition in the "Arabian Nights Entertainments," Burton's edition.

I am, Sir, yours, &c,

GEORGE FOY.

January 6th, 1896.

PROPOSED MEDICAL TITLES BILL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The aim of my too brief previous letter was to help check what would surely prove a great waste of force, namely, an attempt to carry through Parliament a Bill with the sole object of preventing legally-qualified medical men not in possession of an M.D. degree from styling themselves doctor. Amendment and consolidation of medical laws are urgently called for in the interest alike of public and profession. If these are to be attained the united forces of the whole profession must be brought to bear, and I hold it would be a misfortune if, instead of joining with the main body, men of influence like Dr. Glynne Whittle should fritter away their strength in efforts foredoomed to failure. Can anyone with a rudimentary knowledge of the history of medical legislation in recent years believe that any Cabinet or any statesmen of ministerial rank will take up a project of law such as Dr. Whittle suggests? And can anyone believe that such a Bill could have the least chance in the hands of any ordinary member of Parliament?

The abuse for which a remedy is sought is surely a matter of internal professional discipline. Colleges and diploma-giving bodies can frame by-laws, and the General Medical Council can declare "disgraceful" the offence of assuming a qualification without valid claim.

It cannot be said that the interests of the public are materially affected by commission of the offence in question, and the difficulties of getting new laws merely for the advantage or protection of any profession are almost insurmountable. Can it be alleged that practitioners holding say, for example, qualifications like L.R.C.P., M.R.C.S., are one whit inferior to holders of M.D. Durham, Aberdeen, or Brussels? Now every medical practitioner is, and always will be, to the public a "doctor," and on all these grounds it is, I hold, out of the question that Parliament will go out of its way to frame and discuss a prohibitive law of the kind suggested by Dr. Whittle.

If the Medical Act were sufficient to prevent unqualified pretenders from assuming medical titles, the question at issue would not be affected. I am certainly astonished to learn from Dr. Bateman that the Medical Defence Union has been in existence many years, and has conducted successfully many prosecutions every year. It

would be interesting, and would attract many new members to the Union, if he would publish a summary of these cases. The proceedings may have appeared in provincial papers, but I do not think they have been published in medical or leading journals. At any rate, there are scores of quacks practising under false pretences in London; and up to within the last few weeks (and for all I know up to to-day) an infamous unregistered venereal quack who has often been exposed in police-courts has displayed his name with the title doctor in letters many inches high on a shop window in one of the principal thoroughfares of the metropolis.

I am, Sir, yours, &c.,
H. S.

Jan. 2nd, 1896.

LUNATIC ASYLUMS.—THE RELIGIOUS QUESTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having read, as a general practitioner, Dr. THEO. B. Hyslop's instructive lecture in the last number of THE MEDICAL PRESS on "The Diagnosis of Insanity," in which he touches with considerable tact and refinement upon the religious element so often associated with these sad cases, I trust you will allow me to broach a question which is certainly one of extreme delicacy, but which nevertheless the medical profession, as guardians of the public health—mentally and physically—are bound to take cognisance. I refer to the religious question as a factor in insanity. We cannot shut our eyes to the fact that many cases of insanity are evolved from or caused by religious enthusiasm outside our asylums; the question then arises as to how far it can be conducive to the welfare of these institutions to allow the clerical influence, which is by no means calculated to strengthen the enfeebled mind, to have its sway? Some years ago I happened, as a student amongst others, to have the privilege of attending one of our large asylums, and a story was related by one of the attendant physicians in which the chaplain was reported to have made some reference on a religious topic in his discourse in the chapel, and which touched the weak point of one of the inmates; whereupon the patient stood up and commenced a violent harangue, whereby it became obvious that religion was no part of his cure. However this may illustrate my meaning, there can be no question but that we live in a restless and excitable age, when the "struggle for existence" becomes daily more intense, and when it behoves all to keep their wits about them. No doubt the efforts of religious enthusiasts, whether in a salvation army or a church brigade or any other sectarian denomination, to cope with public immorality are commendable enough, but we cannot shut our eyes to the fact that a good deal of insanity and its twin-sister hysteria must necessarily arise from any violent disturbance of the public mental equilibrium owing to religious excitement, and it therefore behoves experts in lunacy to be on the alert and use their influence, lest the good intentions of these enthusiasts should defeat their ends.

I am, Sir, yours, &c.,
CLEMENT H. SERS.

Queen's Road, Peckham, Jan. 3rd, 1896.

Literary Notes and Gossip.

Dr. MURRELL has a new work in the press entitled "Pharmacology and Therapeutics," specially written to meet the requirements of the Conjoint Board of the Royal Colleges of Physicians and Surgeons.

Mr. ALLINGHAM is now engaged on a sixth edition of his well known work on "Diseases of the Rectum." In this edition the author will be associated with his son Mr. Herbert Allingham, the author of "Colotomy."

Dr. J. COWAN WOODBURN, Lecturer on Dental Surgery at the Glasgow Royal Infirmary, will shortly issue a handbook specially designed for medical students, on

"Tooth Extraction," with notes on the Physiology and Anatomy of the Teeth."

We understand that the first edition of Mr. LENOX BROWN'S "Diphtheria and its Associates," is already exhausted, and that a second is in the press. The sale having been so rapid, very few alterations will be necessary in the text, but the value of the plates will be enhanced by two additional colour printings.

THE Government of India has ordered that copies of Mr. HANKIN'S pamphlet, entitled, "The Cause and Prevention of Cholera," shall be issued to all medical officers with instructions to record the result of any experiments made by them, and to communicate the results direct to Mr. Hankin at Agra.

THE season has been more marked than any previous one in the variety and number of diaries, visiting-lists, &c.; besides those previously noticed in these columns, a neat little vest-pocket diary, bound in leather, with gilt edges, has been sent us by Messrs. LEVER BROTHERS, of Sunlight and Lifebuoy Soap celebrity. This miniature volume will be found very useful to carry about for ready reference and short memoranda.

OF European libraries, only four have over 1,000,000 volumes, namely, Bibliotheque National, Paris, 2,280,000 books and 80,000 MSS.; British Museum, 1,500,000 books and 100,000 MSS.; Public Library, Munich, 1,000,000 books, and 26,000 MSS.; Imperial Public Library, St. Petersburg, 1,000,000 books and 26,000 MSS.

THE great Biennial Prize of £800, granted by the Academy of Sciences of Paris, has been awarded to Professor RAVULT, of Grenoble, in respect of his researches in physics and chemistry. His methods of investigation of the constitution of molecular bodies have been adopted by scientists throughout the world.

THE January number of the *Edinburgh Medical Journal* contains a goodly array of interesting original communications. Dr. BALLANTYNE writes on "Teratogenesis: an inquiry into the Causes of Monstrosities"; Surgeon-Major MACDONALD on "A Case of 'Bore' of the Abdomen by an Elephant's Tusk"; and Dr. ROBERTSON continues his paper on the "Pathology of the Nervous System in Relation to Mental Diseases." Altogether the number is a good one.

THE importation of two American books—one on anatomy, the other on surgery—has been stopped in this country under the Copyright Act, whole chapters having been taken from English works without acknowledgment. We had hoped our American friends were getting beyond literary piracy, and were intent on original work on their own account.

"SPLANCHNOLOGY," being the fourth part, Vol. III., of "Quain's Elements of Anatomy," has just made its appearance under the editorship of Professor SCHÄFER and Symington. This now classical work was first published in the early part of the present century. In 1845 Dr. Quain died, and the fifth edition was undertaken by Mr. Richard Quain and Dr. Sharpey. Subsequently Dr. Allen Thomson and Dr. Cleland became editors, all of whom, with the exception of the latter, have gone over to the majority. With the issue of the present part the work is completed in three volumes of eight parts, the publishers being Messrs. Longmans, Green & Co.

"HEALTH Notes for the Sea-side" is a little brochure by Dr. A. C. DUTT, late Senior House Surgeon at the Scarborough Hospital. It contains short chapters on various subjects relating to the preservation of the health. In the chapter "on smoking" he defines what he considers to be the maximum amount of smoking in which a man above twenty-five may indulge daily as follows:—"Six pipes of good tobacco or six good cigars, or twelve to fifteen cigarettes made of good tobacco." The statement about the cigars is interesting. Most people who are not millionaires have probably few opportunities of judging

what a good cigar is. The author writes in a chatty popular style, and we can commend his contribution to the subject of personal health.

UNDER the title of "The Students' Practical Materia Medica" Mr. Giffen has published a short compendium of useful notes. For some mysterious reason, best known to themselves, the originators of our official materia medica have adopted a most haphazard system of dosage. In order to overcome this stumbling-block the author has introduced a method of grouping together various preparations according to the dose. Thus, he divides the tinctures into four groups, namely, those that can be taken in doses of (1) $\frac{1}{2}$ —1 dr.; (2) 10—30 min.; (3) 5—10 min.; and (4) those not taken internally. This little book is issued by Messrs. Livingstone, at the modest sum of 2s. It contains much useful information for those wishing to arrange and revise their knowledge for examination purposes.

UNDER the title of "The Home of the Jackdaws" the well-known and popular Registrar of the General Medical Council has issued a reprint of one of his chatty and interesting little articles on bird life. The jackdaw, as pointed out by Mr. Miller, has been patronised by writers of every kind, ancient and modern. The particular "Home" which is spoken of in the pamphlet is not mentioned by name, but simply alluded to as a "perfectly ideal bay on our South Coast." The jackdaw is among our most characteristic British birds, and one can well understand the interest and admiration which it has evidently excited in the mind of the author. From time to time it has been our pleasant duty to welcome similar essays from the same pen. Mr. Miller has been a life-long student of birds and of bird-lore. The present article is reprinted from *Nature Notes*.

A NEW quarterly journal has recently made its appearance in London under the title of *The West London Medical Journal*. It is edited by Mr. Percy Dunn, and is published under the auspices of the West London Medico-Chirurgical Society, of which well-known body it is the official organ. There is certainly room for such a publication, which will preserve in book-form many valuable clinical observations, the waste of which in the smaller societies throughout the country has long been a commonplace subject for recurrent editorial regret. The main part of the initial number of the *West London* is taken up by the Presidential address and by papers and a discussion on the eminently practical subject of gastric ulcer, most of which has already appeared in our columns. The "Mirror" of clinical reports is a useful feature of the journal. The editor may be heartily congratulated on the excellence of his first issue, and the Society on its enterprise in undertaking a somewhat arduous task.

A VERY amusing discussion is at present in progress between the editor of the *New York Medical Record* and the editor of the *Philadelphia Medical News* upon the subject of spelling. In a very modest way we have ventured ourselves on many occasions to animadvert upon the method of spelling adopted by our latter esteemed contemporary, and the following is what the *New York Medical Record* has to say on the subject: "Our contemporary, the *Medical News*, has a reprehensible habit of misspelling a good many words and an obstinacy in holding out, even when convicted of error by every other authority, as well as by incontrovertible facts." The discussion has turned in this instance upon the words "uranalysis" and "symphyseotomy." The editor of the *Medical News* objects to each, while the editor of the *Record*, in an interesting leading article, justifies their existence etymologically, and points to the fact that the "e" in symphyseotomy is correct, inasmuch as the stem of the word is *φυσ*. It is refreshing to see that at least one of our contemporaries on the other side of the Atlantic has made a stand against the policy of "clipping and changing" which at present disfigures the words in many American medical journals.

"OUIDA" is nothing if she is not up-to-date. In her last novel, euphemistically called "Toxin," she takes full advantage of the anti-toxin treatment of diphtheria,

and evolves out of it all sorts of "horror" by the aid of her imagination. The novel receives its title from the fact that the toxin of diphtheria is employed by the villain to rid himself of his rival. Characteristically of "Ouida," the villain is no puppet or insignificant person of low birth and intelligence, but a man of science, concerning whom she says "the infliction of death was nothing to him. He was used to kill as he was used to torture, with profound indifference—with no more hesitation than he ate or drank or fulfilled any natural function of his body. To obtain knowledge, even the approach of knowledge, he would inflict the most agonising and most endless suffering without a moment's doubt or regret." After this it is easy to understand how "Ouida" makes the scientist inject into the veins of his sleeping friend, who was recovering from diphtheria, the toxin of the disease instead of the antitoxin. Poor "Ouida"! What can be the matter with her? Has she been reading Max Nordau on "Degeneration," and imbibed some of his ideas of "going" for everybody?

UNDER the specious title of "Our Treasures and How to Keep Them" we are favoured with a synopsis of the principles of nutrition and diet, in which special emphasis is laid upon the importance of an adequate proportion of fat. It is a matter of common experience that the very persons who stand most in need of fat are precisely those in whom this alimentary substance excites positive loathing, and the problem arises how best to coax them into absorbing a sufficient quantity of a necessary but, to them, repulsive article of diet. The writer of this pamphlet claims to have solved the problem by showing that Virol is a very palatable and digestible form of nutritive fat. Without endorsing the writer's thesis in all its details, we may concede that he eloquently pleads the advantages of a dietary comprising bone-marrow duly prepared for consumption in the form of "Virol." Virol, we are told, contains a large proportion of the red marrow which, while it adds to the cost, materially enhances the value of the preparation. Marrow, on the other hand, is a combination, in physiological proportions, of the yellow marrow of ox-bones, with extract of malt. This is not the place to discuss the value of food preparations, but the *brochure* (a copy of which can be had on application to the Liquor Carnis Co.) contains a number of useful recipes which will prove serviceable in arranging the dietary of invalids requiring substantial and easily assimilable nourishment.

WE have received from Messrs. Burroughs, Wellcome and Co., an "Anti-diphtheritic Treatment Chart," for the purpose of recording the progress of cases treated by serum injections. The chart will doubtless prove useful, and for the most part the points to be observed are pertinent and well selected. In any future issue, however, we would suggest—First, that the term "Diphtherial" should be substituted for "Diphtheritic," the latter word tending to perpetuate the assumption of a grade of inflammation which, as Trousseau pointed out nearly forty years ago, does not exist. Secondly, it is not the "maxillary glands" which are primarily or ordinarily enlarged in diphtheria, but the cervical, and under this heading it would be well to ask which set of glands were enlarged, as clinical distinction is thereby given to the nature and severity of an attack. There is also another omission in that no provision is made for the recording of concomitant general or local treatment, nor of alcoholic stimulants. Lastly, while approving of "the adoption of physiological rather than a mechanical means of dosage," we would point out that we are not thereby further helped than formerly, with information as to what proportion of "a therapeutic adult dose" should be adopted for an infant. As a matter of fact, larger doses are being used for children than for the adult, and the only standard of dosage seems to be that of the malignancy of the attack, the intensity of which is usually in an inverse proportion to the age of the patient.

NEW BOOKS AND NEW EDITIONS.—The following have been received for review since the publication of our last monthly list:—Quain's Elements of Anatomy, Edited by E. A. Schäfer, F.R.S., and Geo. D. Thane, Vol. iii., Part IV. The Year-Book of Treatment for 1896. History of the Cholera Controversy, by Sir George Johnson,

M.D. Hygiene, by J. Lane Nottor, M.D. Dub., and R. H. Firth, F.R.C.S. **A History of the Chronic Degenerative Diseases of the Central Nervous System**, by Thos. K. Monro, M.A., M.D. **The Physiology of the Carbohydrates; An Epicriticism**, by F. W. Pavy, M.D., F.R.S. **Appendix to the Medical Digest from 1891 to 1895**, by Richard Neale, M.D. **Skiascopy and its Practical Application to the Study of Refraction**, by Edward Jackson, A.M., M.D. **Lectures on Appendicitis**, by Robert T. Morris, A.M., M.D., New York. **Modern Medicine and Homoeopathy**, by John B. Roberts, A.M., M.D., New York. **The Thyroid Treatment of Myxoedema**, by Byrom Bramwell, M.D. **Local Government Board Reports and Papers of the Port and Riparian Sanatory Survey of England and Wales. The Middlesex Hospital Reports for 1894. The Inebriety of Insanity from a Medico-Legal Point of View**, By T. D. Croshers, M.D.

Obituary.

MR. ARTHUR JACKSON, M.R.C.S., OF SHEFFIELD.

We have with much regret to announce the death of Mr. Arthur Jackson, the well-known and popular surgeon of Sheffield, which took place, on the 29th ult., after a short illness. Up to the 10th of last month he appeared to be in his usual health. On the evening of the 8th he presided over an important meeting of the Sheffield Medical School having relation to the amalgamation of the School with Firth College and the Technical School for the purposes of the Victoria University scheme. The day following, among other meetings, he attended a meeting of the Council at Firth College, when the arrangement for amalgamation was concluded. On the morning of the 10th, however, he complained of feeling unwell, and suffered from severe abdominal pain. This continued throughout the day, but despite this Mr. Jackson continued to attend to his professional duties. Subsequently the pain increased, and his condition became serious. The symptoms at first yielded to treatment, but a relapse followed, complications ensued, and death took place as recorded above. His age was 51.

Mr. Arthur Jackson was born on February 21st, 1844. He was the second son of the late Mr. Henry Jackson, M.R.C.S., of Sheffield. Mr. Henry Jackson, it may be stated, was the only son of the eminent surgeon of that name. The subject of our memoir received his early education at the Collegiate School, and afterwards studied at Cheltenham College. His medical knowledge was gained at the Sheffield School of Medicine, at the General Infirmary, where he was pupil under his father, and at St. Bartholomew's Hospital, London. In the year 1866 he had gained his surgical qualification (M.R.C.S. Eng.), and no doubt would have won further degrees, but in that year his father died, and it became necessary for him to take up the practice.

Like his father, Mr. Arthur Jackson was a great collector of rare and curious books, and possessed an extensive knowledge of local antiquities. Early in life he turned his attention to the history of his native city, of which he was intensely proud, and he frequently gave lectures upon this subject. His exertions on behalf of the medical charities of Sheffield were such as to endear him to all those who were obliged to use those institutions. For several years he was surgeon at the Sheffield Royal Hospital, and continued to occupy that post until he became surgeon at the General Infirmary. At the time of his death he was senior surgeon at the latter institution, and also consulting surgeon at the Hospital. He succeeded the late Mr. Bernard Wake as treasurer to the Royal Hospital in 1891.

His contributions to the medical journals were not numerous; the last that appeared from his pen was published by the MEDICAL PRESS AND CIRCULAR in 1884, the paper being entitled "A Quarter of a Century's Surgery." He took a large share in the public duties of his town, and he held many appointments in connection therewith. Moreover, he was the lecturer on Surgery at the Sheffield Medical School. He lived an active, busy life, and enjoyed a large measure of popularity among those with whom he came into contact. His untimely decease has led to widely spread expressions of regret in Sheffield, where among all classes he was held in high esteem.

Medical News.

The Jenner Memorial Fund.

We are asked to announce that the collection of "Jenner Relics" got together by Mr. Frederick Mockler, of Wotton-under-Edge, has been accepted by the Dean and Faculty of Medicine, University College, Bristol, to be located there, provided that the necessary amount to purchase it from the owner can be raised by public or other subscription. The fact that Dr. Edward Jenner, who was born (1749), lived, made his famous discovery of vaccination, practised, and died (1823) at Berkeley, in Gloucestershire, has suggested the idea that this unique collection of memorials of the life and career of one of the three greatest names in English medical science should be secured for the county and located in its capital city, Bristol. A large number of gentlemen have already promised to subscribe to the Fund—Earl Fitz-Harding contributed £10 10s.—and further subscriptions are solicited. We think it a mistake, however, that no sum is mentioned in the appeal, because if the purchase of the relics have for its object the putting of a profit into the pockets of a collector of antiquities, the profession will not so readily subscribe. The centenary of Jenner's experiment, which gave the incalculable benefits of vaccination to the world, will be May 14th, 1896. In Russia preparations are being made on an extensive scale to commemorate this event, and it is to be hoped by the committee of this fund that the collection may be placed in the College in anticipation of that period, so as to worthily celebrate the event here. Cheques should be made payable to "The Jenner Memorial Fund," and crossed "Messrs. Prescott, Dimsdale, Cave, Tugwell & Co., Ltd., Bankers, Bristol."

Formation of a Medical Society at Bedford.

A MEETING of the medical men of Bedford and district was held at the Infirmary on Thursday, January 2nd. Mr. Hughes Hearnings, of Kimbolton, occupied the chair. It was decided to form a medical society in Bedford "for the promotion of professional intercourse, for the reading of papers, for the exhibition of cases, patients, pathological specimens, &c., and for the discussion of all questions affecting the welfare of the profession." Meetings will be held at the Infirmary quarterly at 3.30 p.m. The following officers were elected for the ensuing year:—President, Dr. G. P. Goldsmith; Treasurer, Mr. A. Chillingworth; Secretary, Mr. W. Gifford Nash.

The Laryngological Society of London.

THE Laryngological Society of London, under the presidency of Dr. Felix Semon, has made great progress, and at its annual meeting, which will be held to-day (Wednesday), a very satisfactory report will be read of its work during the past year. The following is the list of officers for the year 1896, nominated by the Council:—President, Dr. Felix Semon; Vice-Presidents, Dr. Cresswell Baker, Mr. Charters Symonds, Dr. Hodgkinson; Treasurer, Mr. W. T. Walaham; Librarian, Dr. Clifford Beale; Honorary Secretaries, Mr. W. R. Stewart and Dr. St. Clair Thompson; Council, Dr. J. B. Ball, Dr. F. W. Bennett, Dr. T. W. Bond, Dr. Scanes Spicer, and Dr. Watson Williams. The meeting will be followed by a dinner in the Café Royal, the President in the chair.

PASS LISTS.

University of London, 1895, B.S. Examination.

THE following is an Official List of Candidates who passed the recent Examination for Honours in Surgery, arranged in the order of merit.

FIRST CLASS.

- Turner, William, (Scholarship and Gold Medal) King's College.
 Russell, Alfred Ernest, (Gold Medal) St. Thomas's Hospital.
 (a) Shaw, Harold Batty, University College.
 Hull, Charlotte Elizabeth, Royal Free Hospital.
 Hunt, George Bertram, University College.
 Sloane, John Stretton, B.Sc., St. Bartholomew's Hospital.
 Pugh, William Thomas Gordon, Middlesex Hospital.
 Bernard, Harold Leslie, London Hospital.

SECOND CLASS

- Thomas, Thomas Morrel, Guy's Hospital.
 Berry, Frances May D., M.D., London School of Medicine for Women and Royal Free Hospital.
 Channing-Pearce, David Arnold, Guy's Hospital.
 (a) Obtained the Number of Marks qualifying for a Gold Medal

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

LOCAL REPORTS AND NEWS—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

REPRINTS—Authors of papers requiring reprints in pamphlet form after they have appeared in these columns can have them at half the usual cost, on application to the printers before type is broken up.

READING CASES—Cloth board cases, gilt-lettered, containing twenty-six strings for holding the numbers of THE MEDICAL PRESS AND CIRCULAR, may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

M.D. LOND.—We have heard of the suggestion before; it is, therefore, not new, as our correspondent supposes. A practitioner in Birmingham, we believe, was the first to draw attention to the matter.

G. L. T.—Our correspondent is thanked for his communication, which will be duly considered.

CRUSHED AGAIN.—"Isn't it awful?" said Mrs. Jenks to her husband. "Isn't what awful?" queried Jenks. "Houston's boy was run over and received infernal injuries." "Infernal, you mean." "No. I mean infernal. I know what I am talking about." After a quarrel of five minutes, Jenks produced a dictionary, and with considerable trouble managed to find "infernal." "There!" he exclaimed, "I told you so. Infernal means, 'relating to the lower regions.'" "Well," replied Mrs. Jenks, and there was a ring of triumph in her voice, "ain't that where he was injured?"

DR. S.—We have referred to the matter in another column. Our correspondent is thanked for his communication.

STUDENT.—Dr. Swanzy's book on the Eye will answer every purpose. It is published by Mr. Lewis, Gower Street, London, W.C.

DR. BLAIR (Torquay) is thanked for his note.

MR. E. S. C. will find the subject referred to in our "Literary Notes" column.

DR. JACKSON.—The matter is likely to occupy the attention of the General Medical Council at its next meeting.

MR. WILSON is thanked for his contribution, but it is scarcely suited for the columns of a medical journal.

F.R.C.S.L.—No information upon the subject has reached us so far.

M.D. (Leicester).—Before taking any action in the matter we should recommend our correspondent to make further inquiries.

THE CLIMATE OF ENGLAND.

THOSE of our readers who are specially interested in this subject will be glad to be informed that Dr. E. Symes Thompson, Gresham Professor of Medicine, will deliver a *free* course of Lectures on the subject at Gresham College, London, on Jan. 21st, 22nd, 23rd, and 24th, at 6 p.m. each evening.

PENSATOR (London).—We do not believe that any action at law could be commenced with such an object.

GENERAL PRACTITIONER (Exeter).—Our correspondent's letter has been handed to our publishers, who will attend to his request.

Meetings of the Societies.

WEDNESDAY, JAN. 8TH.

HUNTERIAN SOCIETY.—8.30 p.m. Dr. J. H. Sequerra: Chronic Pyaragel Affections and their Relation to Diphtheria. Dr. Fortescue Fox: Localised Rheumatoid Arthritis.—Mr. Percy Warner: Some Notes of a case of Typhlitis.

LARYNGOLOGICAL SOCIETY OF LONDON (30 Hanover Square, W.).—4.30 p.m. Annual General Meeting. Cases, Specimens, &c., by the President, Dr. Barclay Barron, Dr. J. W. Bond, Dr. Bronnor, Dr. Cooper Cripps, Dr. William Hill, Dr. David Newman, Mr. C. A. Parker, Dr. Soames Spleer, Dr. St. Clair Thomson, and Dr. Herbert Tilley. 8 p.m. Annual Dinner (O-Jé Royal).

SOUTH-WEST LONDON MEDICAL SOCIETY (Windmill House, Clapham Common). 8.30 p.m. Mr. W. G. Dickinson: Professional Unionism. A Discussion will follow.

THURSDAY, JAN. 9TH.

BRITISH GYNECOLOGICAL SOCIETY (30 Hanover Square, W.).—8.30 p.m. Mr. Fredk Edge (Wolverhampton): Notes on a case of a Paratero Vaginal Fibroid Tumour treated by Removal of the Appendages and Dissection out of the Growth. Mr. Bowreman Jessett: The Difficulties of Diagnosing Early Carcinoma of the Body of the Uterus (with specimen).

HARVEIAN SOCIETY.—Mr. Edmund Owen: Children's Spines—Healthy, Unhealthy and Otherwise.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY (Great Northern Central Hospital, Holloway).—8.30 p.m. Specimens and Clinical Cases. Dr. Arthur Wilson: Case of Perforating Ulcer of the Stomach. Dr. C. E. Beevor: Case of Arsenical Neuritis. And other cases.

SOCIETY FOR THE STUDY OF INEBRIETY.—4 p.m. A Quarterly General Meeting, the President, Norman Kerr, M.D., F.R.S., in the Chair. Paper:—W. H. Kesteven, M.R.C.S., Member: The Proper Method of Dealing with Habitual Drunkards.

FRIDAY, JAN. 10TH.

CLINICAL SOCIETY OF LONDON.—Dr. David Newman: Intermittent Hydro-nephrosis and Transient Albuminuria in cases of Movable Kidney.—Dr. Lee Dickinson: Cases of Spontaneous Thrombosis of the Cerebral Veins and Sinuses in Chlorosis.—Dr. Ringer and Dr. A. G. Fear: A case of Addison's Disease, treated with Supra-Renal Extract (with an abstract of previously recorded cases).—Dr. Hale White: Two cases of Pneumo-Thorax in the course of Typhoid Fever, and both due to straining at stool.

MONDAY, JAN. 13TH.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—8 p.m. Dr. Dudley W. Burton will read a paper entitled "An Appended Note on Anæsthesia." Usual Communication:—Mr. J. F. Colyer: "Some Cases of Open Bite."

Vacancies.

Carrick-on-Suir Union.—Night Nurse. Salary £25 per annum, with rations and apartments. Election 11th January (see advt.).

Medical Registrar.—Branch Medical Council, Ireland. Election 16th January (see advt.).

Metropolitan Asylums Board.—Assistant Medical Officer for the Small-pox Hospital Ships on the Thames. Salary commencing at £180, with board, lodging, and attendance. Applications to the Clerk of the Board (see advt.).

Appointments.

BREIDING, D. T., L.R.C.P.Lond., M.R.C.S., Medical Officer by the East Dereham Urban District Council.

GABRIANG, T. W. H., M.R.C.S., Medical Officer of Health by the Bucklow Rural District Council.

HALE, G. E., M.B., B.C.Camb., L.R.C.P.Lond., M.R.C.S., Medical Officer by the Eton Board of Guardians.

FERRIS, C. I., L.R.C.P., L.R.C.S.Irel., Medical Officer of Health by the Kingswood Urban District Council.

FRIER, R. S., L.R.C.P., L.R.C.S. Edin., L.F.P.S.Glasg., Assistant Medical Officer of the St. Andrew's District, and Medical Officer of the Ovenstone Hospital.

ROBERTS, A. H., L.R.C.P.Lond., M.R.C.S., Medical Officer of Health for the Malling Rural Sanitary District.

ROB, A. J. S., L.R.C.P., L.R.C.S.Irel., Resident Surgeon to the Hull and Sulcoates Dispensary.

ROB, A. L., L.R.C.P., L.R.C.S.I., Honorary Ophthalmic Surgeon to the Hull and Sulcoates Dispensary.

SADLER, F. J., M.B., B.Ch., Oxon., Assistant Medical Officer of Health by the Barnsley Town Council.

SNOWBALL, W., M.B., Ch.B. Weib., L.R.C.S. Edin., a Member of the Medical Board of Victoria, Australia.

SPOER, S., M.D. Lond., M.R.C.S., an Honorary Physician to the Royal Society of Musicians of Great Britain.

STEWART, G. E., M.B., C.M. Edin., Assistant House Surgeon to the Scarborough Hospital and Dispensary.

THOMPSON, H. C., M.D. Lond., M.R.C.P., Medical Registrar to the Middlesex Hospital.

Births.

ALEXANDER.—Jan. 5th, at Teonmash House, Southsea, the wife of S. P. Alexander, M.D., M.R.C.S., of a son.

ALLPORT.—Dec. 24th, at Wilham, Casewick Road, Norwood, the wife of Alfred Allport, M.R.C.S., of a daughter.

KENT.—Dec. 23rd, at 3 Minard Terrace, Partick Hill, Glasgow, the wife of B. T. Kent, M.A., Oxon., F.R.C.S., of a son.

WILKINSON.—Dec. 26th, at Kiron, Boston, Lincolnshire, the wife of John Wilkinson, M.B., C.M. Edin., of a daughter.

Marriages.

GROSS-HARKER.—Dec. 28th, at the Parish Church, Blarhall, Suffolk, Charles Frederick Gross, M.R.C.S., L.R.C.P., son of Arthur Spurling Gross, of Woodbridge, to Dorothy Lucy, younger daughter of the late James Cumming Harker, of Liverpool.

Deaths.

FRENCH-MULLEN.—Dec. 26th, at his residence, at 16 Warrington Place, Dublin, Fleet-Surgeon St. Lawrence French-Mullen, R.N., M.D. (retired).

FROGE.—Jan. 2nd, 1896, at Westville, St. Mary Church, Torquay, Thos. Finch, M.D., M.R.C.S.

HILLES.—Dec. 31st, at his residence, Elm View, Highfield Road Bathgar, Malcom William Hilles, L.R.C.S.I., in the 89th year of his age.

HUNT.—Dec. 27th, suddenly, at Christchurch, Hants, Bertram Hunt, M.B. Oxon., M.R.C.S., aged 89.

JACKSON.—Dec. 29th, at 53 Wilkinson Street, Sheffield, Arthur Jackson, M.R.C.S. Eng., in his 52nd year.

JACKSON.—Dec. 22nd, at Shepherd's Bush, London, Richard Jackson, M.R.C.S. (Eng.), L.R.C.P. (Lond.), L.S.A. (Lond.), fourth son of the late Richard Jackson, Beechwood House, Fulford Road, York.

NOTICE—Announcements of Births, Marriages, and Deaths in the families of Subscribers to this Journal are inserted free, and must reach the publishers not later than the Monday preceding publication.

The Medical Press and Circular.

No. 3.

Lectures

ON

THE DIAGNOSIS OF INSANITY.

By THEO. B. HYSLOP, M.D.,

Lecturer on Mental Diseases to St. Mary's Hospital Medical School,
Assistant Physician to Bethlem Royal Hospital.

LECTURE III.

OUR social environment may influence us morally and intellectually, and it is undoubtedly owing to our conformity to the relative duties of social life that we adopt our prevailing tone of thought and conduct. As we advance in life these social influences gradually increase in complexity. How moral law influences social life, organisation, and government is too complex a question to consider; here we have but to note that members of a society may combine to predispose the generation of a morbid psychosis. Epidemics of feverish excitement, excessive religious enthusiasm, and even insanity, at times affect vast numbers of people. These neurotic storms have been described elsewhere (a) as having been characterised as purely mental or moral perversions, or as physical aberrations secondary to physical contagion.

The insane are apt to derive their delusions from whatever excites much public attention. The revolting crimes as recorded in our daily papers are apt to influence the direction of the morbid thoughts of the insane. Thus, for instance, during the period of the Whitechapel murders innumerable patients accused themselves or others of being Jack the Ripper. Insanity may be endemic, or it may extend and become epidemic. The perversions may manifest themselves in the form of illusions or pure hallucinations which affect many persons at the same moment; morbid psychoses in which there may be melancholia; excessive religious zeal, political or pseudo-scientific intemperance; sensory perversions with ecstasy, impulses and morbid activities; actual convulsive attacks as in the various epidemics of hysteria, epilepsy, and chorea. In dealing with insane people, therefore, we have to remember that what we accept as evidence of insanity may be but an endemic or epidemic psychopathy which exists throughout a large number of individuals. Some religious delusions are confined to the members of particular religious bodies, but, however widely they differ from our standard of truth it is well to estimate them as possibly fallacious beliefs and not as insane delusions. Later we shall have to speak more particularly about insane delusions, so now we have merely to note that religious delusions may arise in connection with various evolutionary epochs and in association with various physical states. Thus, they accompany the mental development of over-stimulated and injudiciously educated children (fear, remorse, &c.), they characterise the insanity of pubescence (fear, depression, and wish to do penance); they are caused by self-abuse (self-conscious, unpardonable sinners, weak-minded, auditory hallucinations, trances, ecstasies, suicides); in association with so-called paronia

(a) "Mental Physiology."

(delusions of superior spirituality, fanaticism); with epilepsy, dementia, and general paralysis (rarely fear, usually unworthiness, or exalted ideas); in melancholia and climacteric insanity (unworthiness, fear of endless life); in chronic mania or toxic insanity (usually exalted).

Having now ascertained as far as possible whether there has existed any hereditary or social factors which would tend to influence the nature of the case under consideration, we next proceed to the study of other factors which tend to modify the life-history of the individual. These factors, briefly enumerated, are:—

1. Causes acting on the parents at time of pregnancy:—
 - (a) Maternal impressions.
 - (b) Moral causes, shock, gynagogues, &c.
 - (c) Disease of parent during pregnancy. (Fever, &c.)
 - (d) Accidental causes at birth, such as, premature, difficult, or instrumental delivery, asphyxia neonatorum, primogeniture.
2. The temperament, constitution, or diathesis of the patient.
3. The influence of general surroundings:—
 - (a) Seasons and climate, moon, &c.
 - (b) Occupations.
 - (c) Town and country life.
4. Accidental factors, such as:—
 - (a) Domestic troubles and grief.
 - (b) Religious anxiety and excitement.
 - (c) Disappointed affections.
 - (d) Fear and fright.
 - (e) Intense study.
 - (f) Political and other excitement.
 - (g) Wounded feelings.

Considered in detail, it will be noted that most of these factors give some clue to the nature of the case before you, and, therefore, their consideration cannot be dispensed with.

Maternal impressions are regarded as giving rise to morbid, mental, and bodily defects. In a paper read before the Obstetrical Society of London, May 7th, 1884, Dr., now Sir, Arthur Mitchell, Commissioner in Lunacy for Scotland, stated that in 6 cases out of 443 in which an effort was made to establish a cause for idiocy, the influence of maternal impressions was clearly traceable. Any prolonged distress is more apt to produce bad effects than a sudden shock or fright, and this more readily during the later months of pregnancy. Undoubtedly bodily defects attributable to maternal impressions are far more common than mental. Whether the mental or bodily defects are accidental, and whether there is direct relation between the brain structures of the parent and child, are questions which we are unable to answer. With regard to the defect in the child simulating the object causing the impression upon the mother it has been pointed out by Dabney that out of 90 cases there was quite a close correspondence in 69. Another point urged by the same observer is, that it is not necessary for a mother to expect a defect in the child for such a defect to occur, whether this defect be mental or bodily. The various conditions that unfavourably influence the foetus in utero may be:—(a) Nervous disturbance in the mother. Hirst records a case in which a woman,

while carrying her child in utero, took delight in watching her husband, a butcher, ply his trade, the child subsequently developing an irresistible inclination to torture and slay. (b) Malnutrition in the mother is sometimes accountable for defective children. (c) Diseases of the endometrium, the womb and its adnexa. (d) Alterations in the maternal blood pressure, and (e) Poisons in the maternal blood may bring about morbid results in the child. Various diseases are said to occur to the foetus in utero. Variola, rubeola, scarlatina, erysipelas, malaria, tuberculosis, septicaemia, syphilis, cholera, typhoid, articular rheumatism, recurrent fever, yellow fever, pneumonia, rachitis, anasarca, spontaneous fractures, luxations and ankylosis, intra-uterine amputations, perforations of intestines, are described as affecting the growth and development of the foetus. Intracranial injuries are liable to occur in difficult deliveries whether the labours are spontaneous or instrumental. Meningeal hæmorrhage, rupture of the longitudinal sinus, with extravasation of blood over the convolutions may give rise to convulsions, asphyxia, and in some cases spastic hemiplegia. Prolonged labour and forceps delivery is the assigned cause of many cases of idiocy. Shuttleworth found that prolonged labour without instrumental interference was the cause of idiocy in 29 per cent. of the cases admitted to the Royal Albert Asylum. He believes that judicious instrumental interference will sometimes prevent such evils. Langdon Down traced in twenty per cent. of 2,000 idiots suspended animation at birth. Griesinger lays some stress upon great anæmia of the mother as a casual element of idiocy. Primogeniture is regarded by some as a predisposing element.

Those psycho-physical differences between men which are designated as temperaments are of interest. When we consider the four *temperaments* described by the ancients, we find that pathological conditions of the mind can be assigned to them with a certain amount of appropriateness. In general, the ancients found either a predominant spontaneity or a predominant receptivity. The former gave the active, the latter the passive temperament, whilst from the greater or less permanency of actions or impressions, they devised a fourfold subdivision. These four temperaments were: The sanguine with receptivity easily but not deeply affected; the melancholic with receptivity capable of being deeply affected; the choleric with quick, vigorous but not durable activity, and the phlegmatic with slow but enduring activity. *Vive la bagatelle*, as the motto of the sanguine type, carries its own consequences. The general paralytic, who believes that he is the happy possessor of fabulous wealth, and seeks to benefit mankind in general, is frequently an individual of the sanguine type, who formerly built castles in the air, but who now realises them pathologically. The feeling of well-being, and the desire to benefit others, are but part of the individual. His perverted and exalted notions have their root in that sympathetic feeling and inclination for sociability so prevalent in this temperament. General paralysis occurring in a person of the melancholic temperament is rarely of the expansive and benevolent type. The delusions are of a melancholic complexion, or, if they are exalted, the exaltation is of a selfish and egotistical kind.

The influence of *seasons and climate* in the production of mental disease is a subject of considerable interest and one to which a good deal of attention has been given. Parchappe, Esquirol, Guislain, Aubanel, Thore, and others, observe as the result of their investigations that attacks of insanity are more frequent during the summer months. Guislain believes there is a relation between the warmth of the atmosphere and mental disturbance. A lengthy consideration of the atmospheric influences, with the relative

value of heat, humidity, and the influence of the various winds as a cause of cerebral injury, would be out of place here, so I propose merely to mention a few points of interest. Although high temperature and rarefaction of the air, with its direct sedative effects—quick evaporation from and inspissation of the blood, results in venalisation and diminished supply of oxygen at each inspiration, yet fatigue, bodily excesses, alcoholic, dietetic, or sexual, and the existence of other constitutional maladies, constitute by far the most important factors in the production of mental disorders. Wallther's experiments show that the heat from the streaming rays of the sun can be actually absorbed by the skin. It would appear more probable, however, that it is by the combination of the sun's rays, a heated atmosphere, and a relative amount of humidity, acting together, that heat is retained in the body. As a true exciting cause, heat, direct and indirect, may be an effective cause, but hygrometric and barometric states of the atmosphere have a special influence upon the general vigour of the constitution, and render a person more or less susceptible to heat, and in this way predispose him to suffer from it. When sunstroke is being considered I shall devote more attention to its factors of causation.

The influence of *occupation* in the production of insanity is a subject of interest, but one to which we must devote very scant attention. The ratio (per 10,000) of the yearly average of the number of lunatics in each profession or occupation, admitted to asylums during the five years 1889 to 1893 inclusive) to the whole population in each profession, or occupation, at the time of the Census of 1891 (Commissioners' Report) was as follows:—Hucksters, costermongers, hawkers, pedlars, 20.1 males, 36.9 females. Physicians, surgeons, and general practitioners, 15.8 males. Woolstaplers, cloth, worsted, stuff, flannel, blanket, silk merchants and dealers, cotton and calico warehousemen and dealers, linen, lace, fustian, tape, thread dealers, Manchester warehousemen, 18.2 males, 24.4 females. Chimney sweeps and soot merchants, 14.2 males. Chemists and druggists, 14.1 males. The other occupations all range below 12.6. The reason why hawkers head the list is uncertain. The medical profession stands midway between warehouse work and chimney-sweeping. One point to be noted is, that although general paralysis is scarcely known in some localities, when the people from these localities go to towns and large centres of civilisation they are just as liable to suffer as others.

Of the accidental factors which cause insanity the most common are:—Domestic trouble (including loss of relatives and friends); adverse circumstances (including business anxieties and pecuniary difficulties). About 5 per cent. of all cases of insanity are due to such causes. Overwork is not infrequently the assigned cause, and undoubtedly too long hours, or too close occupation, with neglect of the ordinary rules for health, will result in mental breakdown. The friends of patients are very apt to assign this as a cause; but it is more common to find that worry or anxiety has been the more important factor. One patient was admitted to Bethlem suffering from acute mania, supposed to be due to overwork; an amended certificate, however, assigned as the cause "over-religious conscientiousness and pediculosis." Careful investigation will generally result in the discovery of a combination of causes which together act as factors in the production of stress or strain.

Religious excitement is also not infrequently an assigned cause. I have stated elsewhere my belief that the philosophy of the infinite, far from being a source of aberrations of thought, is the ultimate point of our evolution. A true and philosophical religion raises the mind above a mere incidental emotionalism, and gives stability. With no religion, and no moral obligation

the organism is apt to become a prey to the lusts of the flesh and their consequences. Gasquet observes, that religion may either produce or tend to hinder unsoundness of mind ; that it may cause certain symptoms of insanity or modify them ; and lastly, that it may be employed as a means of moral prevention and treatment. He believes that every form of religion, however widely it may differ from our standard of the truth, if it enforces the precepts of morality, is a source of strength to the sound mind that sincerely accepts it. Clouston has justly observed that far more depends upon the brain that goes to church than upon what it may obtain in the church. That is to say, there must be the predisposition to break down, the religious influence being often merely an accident. It must also be remembered that religious over-enthusiasm may be merely a symptom and not a cause.

Love affairs do sometimes act as exciting causes of insanity. Disappointment at being jilted has been the main factor of causation in several cases recently admitted to Bethlem. Some youths break down when they become engaged to be married, owing to nervousness and fear lest they should not be able to perform their sexual functions satisfactorily. I have seen not a few of these cases, and possibly some of the suicides which occur just before marriage was to have taken place may be explained in this way.

Widowhood, with its unsatisfied cravings ; too lonely and isolated a life ; the worries and wounded feelings in the trying life of a governess, all may be assigned as potent factors in the production of morbid psychoses.

(To be continued.)

DIMINISHED RESPIRATORY FUNCTION AND FATTY DEGENERATION IN TROPICAL CLIMATES.

By SURGEON-GENERAL CHAS. R. FRANCIS, M.B.,
M.R.C.P. Lond.,

Formerly of H.M. Indian Army, and Officiating Professor of Medicine in the Medical College, Calcutta.

In his paper on "The Effects of Change of Climate on the Human Economy," published in the "Proceedings of the Royal Society" (1869-72), Surgeon A. Rattray, R.N., states that there is a diminution of the respiratory function in persons going from a cold to a hot climate, causing thereby a reduced elimination of carbon by the lungs. It had already been shown by Vierordt and Ludwig (quoted by Professor Parkes) that heat lessens the number of respirations in animals.

When attached to the Medical College, Calcutta, in 1865-66, I observed (and recorded the observation in the *Indian Medical Gazette*) that the lungs of Europeans who had lived and died in the plains of India were lighter than the average weight of these organs in England. Noticing this statement in his "Practical Hygiene," Parkes, who some years previously, when in India, had remarked the same condition in the lungs of persons dying from cholera, expressed his opinion that, if these observations could be verified by further inquiry—so far, they were too few—Rattray's experiences would be confirmed. Acting upon this hint, I applied to Sir A. D. Home, at that time Director-General of the Army Medical Department, Bengal ; to Dr. Coates, Principal of the Medical College, Calcutta ; to Dr. S. C. Mackenzie, Superintendent of the Presidency jail there ; and to Surgeon-Major W. R. Cornish, Sanitary Commissioner for Madras ; all of whom not only furnished me with the information that I sought, but procured for me, also, the assistance of other medical officers—of Dr. J. F. P. McConnell, Professor of Pathology in the Medical College, Calcutta ; of Drs.

Hugh Johnstone and Saffney attached to the College Hospital ; and of Surgeon-Major A. Porter, Surgeon 4th District, Madras, who had contributed some notes on the pathology of famine disease, including the weights of various organs. Sir Anthony Home furnished a table showing the weights of the lungs, liver, spleen, kidneys, as also the heights, of 147 European soldiers, who had resided, on an average, from 5 to 6 years—the maximum being 24 years and the minimum 1 month—in the plains of India. It is perhaps to be regretted that the weight of the entire body, with the proportionate weight of the lungs, was not given in each case, I applied for information on the subject to Netley, where the body weight, as well as that of organs, is always taken ; but, unfortunately, it was not available.

The average weight of the lungs in a temperate climate is, according to Gray, 43 ounces in males, that in females being something less. According to Dr. Home's table, the average weight in India is 38 ounces. All the phthisical cases—12 in number—in which the average weight was 76 ounces, (in one case the weight was 114 ounces, in another 100 ounces, in three above 80 ounces, the others also being very high)—were, of course, excluded in striking the average, together with those in which there was *much* engorgement—slight hypostatic congestion was not considered—from pneumonia, from interference with the circulation, or from other causes. There may have been some few cases due to feebleness of the heart's action shortly before death. It is probable that, if the lungs had been carefully drained in each case, the weight would have been even less. In the tables furnished by Drs. Coates and McConnell the average weight, excluding a case of gangrene (77 ounces), and the phthisical cases, with those of extensive engorgement, was 38½ ounces. Whilst in those prepared by Drs. Hugh Johnstone and Saffney it was 30 and 27 ounces respectively. Among these last most of the men had resided several years in the plains of India. The European soldier's is, normally, a healthy life ; the Europeans, who resort in sickness to the Medical College Hospital, vary in constitution. A few may be hale and hearty sailors who, living for the most part at sea, are struck down on arrival in a tropical port by some fell disease—cholera it may be—and present lungs which, from the sailor's mode of life, kept inflated to the full, are above the average weight. But the larger number are degenerated Europeans who, for many years, have lived a life of dissipation in the back slums of Calcutta—a life calculated, in such a climate, to considerably *diminish* the weight of the lungs. Eurasians, being for the most part born in the country and approximating to the natives in habits and physique, and whose lungs would, therefore, be lighter than those of Europeans, have not been included. The lungs of natives living in the plains, except in cases of phthisis, or engorgement, or solidification from pneumonia, &c., are always lighter. In the table of 82 natives (excluding Chinese, Portuguese, and natives of other countries)—there were none from the Indian hills, unfortunately, for comparison—furnished from the college hospital, the average was under 30 ounces ; and, in one of 99 males from the presidency jail, it was 29 ounces. The average weight of the lungs in 220 males, examined by Surgeon-Major Porter, was 14·9 ounces and 12·69 ounces in those of 152 females. But, being *famine* cases, they were not, of course, included.

The diminished weight of European lungs in a tropical climate is thus—the size and weight of an organ being in proportion to its activity—in harmony with Rattray's observation of the diminished respiratory function there. (Another inquiry, however, is desirable, as well in temperate and cold as in tropical regions.) Rattray found that the inspirations were, in the last, gentler and less deep—more superficial in fact—causing a difference of 38·65 cubic feet of car-

bonic dioxide eliminated in 24 hours, or 8.157 ounces of carbon in a tropical, against 10 ounces in a temperate, climate; giving 18.43 per cent. in favour of the latter. It is remarkable that, whilst the respirations were fewer, the spirometric measurements were greater, due, Rattray believed, to there being more air but less blood in the lungs.

The question naturally arises, What becomes of the non-eliminated carbon? Unhappily, Europeans with means, so far from reducing the quantity of food and apportioning the quality to the requirements of the system in a hot climate, are too apt to increase the former and altogether ignore the latter. Consequently, unless the excess of carbon be eliminated through some emunctory, it must remain in the body, causing fatty deposits or fatty degeneration of tissue. The liver is usually regarded as an organ that, in a tropical climate, acts vicariously for the lungs. But there is no decided evidence of this. It does not appear that there is a daily compensative flow of bile, though Lawson (quotes Parkes) maintains that there is an increased discharge of colouring matter through the intestinal canal. Undoubtedly, in imprudent individuals there is a tendency to hepatic derangements, accompanied by an increased biliary flow. But they do not occur as a matter of course. We cannot affirm that liver disorder is *invariably* due to climate which, rather, as a rule, tells more upon the nervous system in the form of initiatory, and—so-called—enteric, fever. One occasionally meets with Anglo-Indians who, ailing perhaps from other causes, or, it may be, not at all, have gone through a lengthened career in India without experiencing any form of hepatic disorder. Increased perspiration, especially in those whose skin acts *very freely*, may, indeed, carry off some of the excessive carbon; but, after all, its capacity for doing so is limited, for, as compared with the lungs, its proportion is only 1 to 38. The fact of the average weight of the liver being slightly higher than in the 147 Europeans (it was a fraction over 4 pounds) proves nothing; as, in a large number there had been irregularity of life, from which, especially as regards alcoholic beverages, the liver would primarily suffer. There were ten cases of abscess, the weight in one being 10 pounds, of which 2 pounds 8 ounces were due to pus. Several had been the victims of malarious attacks, in which there would be congestion of this organ as well as of the spleen—all tending to increase the average weight; as such cases, except where the congestion was not excessive, were not excluded.

The kidneys act less freely than in a temperate climate; but as they serve as a channel for the removal of waste *nitrogenous* products, their action in this connection need not be considered. There is, in fact, no sufficient outlet for the extra carbon which accumulates, not only from diminished respiration, but from reduced ingress of oxygen—the result of the air becoming more rarefied in the hot season, especially in sandy districts.

Sudden death in India has been frequently found to be due to fatty degeneration of the heart—more so than in a temperate climate—the consequence, doubtless, of reduced combustion. These facts point to the disadvantage of a prolonged continuous residence in the *plains* of India, and the great benefit to be derived from occasional changes to cooler climates. All cannot enjoy these climates, but all can enjoy free exercise in the open air in the cold weather, thus partially neutralising by freer expansion of the lungs the diminution in the hot months. It is necessary for the lady who, soon after sunrise at this season, has the house darkened (all doors being closed), and thus goes through a process of bleaching for six months or more; for the merchant in his office, and for the civilian in *kutcherry* (law court) who spend their days in a foul and unventilated atmosphere. Herein the indigo and tea-planters (provided the localities where they live are not malarious)

who are much in the open air all the year round—even the racquet player if an abstainer from pegs in the hot season—have a great advantage. They, of course, who can get away to the hills or home from time to time (as in the case of military officers and civilians)—happy they who hold appointments in the former, are much better off; but, from the European soldier—except in the case of deserving non-commissioned officers who are sometimes granted temporary leave of absence, these facilities are withheld. During the last half century the Himalayas and other hills have been explored for the location of European troops—in dépôts for convalescents, as also in cantonments for wings of, or for full, regiments. The last is a most important point and cannot be too strongly insisted upon. It would be a great gain to the Army in a sanitary sense if, as has been frequently pointed out, troops, instead of being sent to the hills *after* a few years' residence in the plains—a period when sickness mostly occurs from fevers, amongst the young men especially—were cantoned, as soon as possible after landing, in a hill station, and allowed to remain there for two or three years. In the enjoyment of the fine hill air the men would roam about, collect butterflies (for boxes of which there is an occasional market in India or at home) and other insects, or get a day's shooting; and, by thus giving freer play to their lungs, contribute to further diminish the loss to the Army, which, nearly 7 per cent. by invaliding and death, 50 years ago, has now been reduced to less than a third of that figure. In barracks in the plains the soldier, in the hot weather, spends half the day asleep on his back, and supplements his rations, already rich in carbonaceous ingredients, with fat bacon from the bazaar. Such practices, combined with the diminished ingress of oxygen into the lungs, tend to induce the fatty degeneration, which injures or carries off so many lives, as has been ably demonstrated by Dr. N. C. Macnamara, when in medical charge of a European regiment, in the 10th volume of the "Indian Annals of Medical Science." And experience has shown that, if suddenly summoned from the mountains to duty in the plains, European troops do not suffer in health as might, perhaps, be expected—witness the 101st Regiment, ordered from Subathoo to take part in the Siege of Delhi in the middle of the hot weather of 1857.

Not only does the prolonged exposure to heat year after year, coupled with the monotonous unexciting life in a military cantonment, tend to curtail the healthy action of the lungs, but it weakens the inhibitory function of the nervous system, thus opening the door for the invasion of disease.

A word in refutation of the theory that India, *the hills included*, is unsuited for the colonisation of Europeans. I venture to differ from their view, as I think we have hardly, as yet, had experience sufficient to justify it. Until within the last few years the practice was to send convalescent soldiers to a hill sanatorium for the hot season, and to bring them back to the plains at the commencement of the cold weather. The salutary result of this arrangement was only partial. The convalescent, in his delicate state of health, was, indeed, saved from the probable consequences of the heat below—doubtless in some cases he derived considerable benefit from the cooler air above—but he lost the tonic effect of a continuously bracing cold weather in the hills, so superior to the uncertain winter at home. Officers and others, whose occupations have required residence there all the year round, hesitate, when the time comes for retirement, to leave their mountain homes, where they have enjoyed uninterrupted good health, for the variable climate of the British Isles. But the attraction of family ties usually prevails, and the risk is run. A case in point recently occurred in my own experience. After many years'

residence with unbroken health in the Himalayas, a military officer, when writing to me, expressed his doubt whether he was wise in thus giving up a certainty of health, humanly speaking, for the reverse. He came contracted an illness, and died within the year. Hill climates vary greatly in character. All are not bracing; some, indeed, in the hot season, being relaxing. The climates of Nynoe Tal and Almorah—the two stations are only 30 miles apart by road and considerably less as the crow flies—are illustrations of this,—the former, though damp in the rains, being invigorating; the latter, in the warm months especially, depressing. To a certain extent, the hills have in the past acquired a bad reputation, partly because this variability of climate has not been sufficiently recognised, the sick being sent to an unsuitable station, and partly because cases have been sent to the hills which would have done better at sea, at home, or even, during the cold weather, in the plains. It is very desirable that, amid the numerous ridges and spurs in the Himalayas, more suitable sites, within a reasonable distance of the plains, should be opened up for the location of European troops, and for convalescent depôts. As the characteristics of the various hill stations—the liability to induce hill diarrhoea, for example—become better understood, this location and adapting of sites to individual constitutions need be a matter of no difficulty. The British soldier's, speaking generally, is a picked life, supposed to be capable of going anywhere; but it may be that, when enlisted, latent seeds of disease had not declared themselves, but been developed subsequently as the result of residence in a malarious station—e.g., in the 36th, many of the men in which regiment manifested tuberculous disease of the lungs during the second year of their stay in Fyzabad. For some of these cases a hill climate would probably be beneficial—not, however, a relaxing one. It will sometimes happen—though rarely with soldiers in health—that elevation does not agree with a man, and that he is better below. The acumen of the medical officer will discover this. It is hardly likely, however, that malingering would assume such a shape! I venture to predict that, in the not very distant future, it will be demonstrated that, with certain precautions, many of the hills in India in each presidency—in the Himalayas especially—will be found very suitable for the colonisation of Europeans. The hill-valleys—attractive chiefly to the sportsman or the botanist—which are apt to be very unhealthy, giving rise to the worst types of fever, cholera, even the plague itself (amongst the natives), constitute one of the principal dangers. But cultivation would greatly improve them; and they need not be visited except in the cold season. At all seasons they should be approached with care—never before sunrise or after sundown, nor on an empty stomach.

"Authorities," generally speaking, do not encourage Europeans who are not well known to settle in the hills, especially where the intending settler has the reputation of having a *garm mixaj* (short temper)—a man "irdacunnus, irritabilis, acer." They, not unnaturally, fear that labour may be driven away, the natives in those parts being so readily intimidated. It may, however, reasonably be hoped that, with the decrease of intemperance in the army and the rousing of angry passions thereby induced the European treatment of the native may become more conciliatory, and more worthy of a conquering race.

Wandsworth, Jan. 2nd, 1896.

His Excellency the Lord Lieutenant has appointed Dr. John Eustace, J.P., to be a Governor of the Richmond District Lunatic Asylum.

Paris Clinical Lectures.

PSEUDO-COXALGIA.

By PROFESSOR DUPLAY, M.D. PARIS UNIV.
Hotel Dieu.

[FROM OUR PARIS CORRESPONDENT.]

I PROPOSE to discuss with you a group of maladies which are not habitually considered in their *ensemble* by clinicians. I refer to those affections, so diverse in their nature, which simulate coxalgia, although in reality there does not exist the slightest lesion of coxo-tuberculosis. Let us, to begin with, take the case of the woman, *æt.* 43, whom you have seen in the wards, and who entered the hospital quite recently. Her antecedents offer nothing very striking. The *début* of the affection dates from three or four months ago, when she felt pain in the right hip which made her limp in walking. She applied various remedies without relief, and as her condition grew gradually worse, she consulted a surgeon, who diagnosed coxalgia and sent her here. If we examine this woman in the horizontal position, with the legs parallel, we fail to find what we should have a right to expect in a true case of coxalgia, viz., either abduction or flexion of the thigh on the pelvis. There exists, it is true, a certain amount of rotation outwards, while rotation inwards is impossible. All other movements are more or less suppressed and excite great pain when attempted. Palpation of the joint reveals two very painful spots: one over the great trochanter, the other inside, corresponding to the obturator foramen. The inguino-crural region is the seat of a tumour of the size of an egg, indolent and fluctuating, not increased in volume by effort or coughing, and irreducible.

A first and superficial examination might incline us to believe it was a case of coxalgia, but closer attention shows that such symptoms as pain in the knee, so characteristic of coxo-tuberculous disease, and abduction and flexion of the thigh on the pelvis, are wanting. To make our diagnosis sure we chloroformed the patient, and we found that all the movements of the joint were possible, consequently the integrity of the articulation was preserved. Let us turn now our attention to the tumour. We find that it is liquid, but devoid of pulsation, consequently it is not an aneurysm; further, it does not communicate with the abdominal cavity, eliminating thus the idea of inflammatory abscess or hernia. Might it be a cold abscess of the ganglions? The hypothesis seems to be doubtful, as the origin of the tumour seems to me to be deep; it is either a hygroma of the bursa of the psoas muscle or a hydatid cyst of the neck of the femur. Our doubts on the matter, in any case, will be cleared up when we proceed to operate.

As I told you at the beginning of this lecture, my intention in giving you the cursory history of this woman, is to present to you some pertinent and practical observations on cases of pseudo-coxalgia. We have here a patient who, suffering from a hygroma of the psoas muscle or an hydatid cyst, entered the hospital for a presumed coxalgia. Now, you will certainly meet with such cases in your private practice in which the symptoms of coxalgia will be even more accentuated, and may lead you to believe in the existence of tuberculous disease of the joint. It is necessary consequently that you should recognise these cases of pseudo-coxalgia, which are more frequent than you imagine, and of which I have made a special study.

We may divide pseudo-coxalgias into two great classes, the first where the articulation is healthy, but where there exists, as in the patient before us, a lesion in the

neighbourhood, and the second, still more interesting, in which not only is the joint intact, but no concomitant lesion is apparent. The lesions of the first group depend most frequently on inflammatory affection of the skeleton, and more especially of the pelvis or the great trochanter of the femur. I remember having treated successfully a young man for osteitis of the great trochanter, who had been previously treated for coxalgia by an eminent surgeon. In another case, that of a boy from Melbourne, the doctors of his country diagnosed coxo-tuberculosis. Examined by my former pupil, Dr. Crivelli, the case was pronounced to be one of osteitis of the epiphysis of the superior extremity of the femur. I was called in and confirmed the opinion of Dr. Crivelli; the child got well without the slightest claudication. One or two years afterwards the same symptoms returned during a voyage through Europe, and his parents this time consulted the first surgeons in Lille, who unanimously pronounced the case to be tuberculous disease of the joint, and recommended the treatment usual in such cases. The patient, however, recovered quickly, and when I last saw him I was able to satisfy myself in respect of the integrity of the articulation.

At other times, affections of the serous bursæ of the neighbourhood of the articulation may exist; I met thus with two cases of suppuration of the serous bursæ of the gluteus maximus simulating in every respect the clinical aspect of coxalgia.

How are we to arrive at a correct diagnosis of such affections? Most frequently you will be struck with the fact that there is something wanting to the usual symptoms of coxalgia; it is thus in our patient—you will find neither abduction nor flexion of the thigh on the pelvis, nor the large lumbar excavation. Or you may remark other signs in contradiction with the ordinary symptoms of coxalgia, and it is in the attentive study of all these details that you will arrive at the truth of the case. Where doubt still exists you must examine your patient under chloroform, by which you will be able, if the articulation is healthy, to establish motions in every sense without provoking the slightest grating.

The second group, as I have already pointed out, consists of cases in which the symptoms of coxalgia are present, but without any lesion of the articulation or of the parts. It was Brodie who, in 1837, drew special attention to this form, which he described under the head of spasmodic coxalgia or articular neuralgia. These terms were replaced later on by Verneuil and Charcot, by that of hysterical coxalgia. The affection is met with more frequently in women, and may supervene at any age, but generally at or about puberty. The malady usually declares itself suddenly from some insignificant cause in a person presenting generally signs of hysteria. In certain cases imitation plays a principal rôle, as in the case mentioned by Paget, where a young girl suffered from hysterical coxalgia whose brother was being treated for a true tuberculous coxalgia. The principal symptoms of hysterical coxalgia are: pain, muscular contractions, and abnormal attitude of the limb. The pain resembles frequently that of true coxalgia, being felt in the knee as well as in the hip, but the seat varies greatly, the patient complaining now in front, now behind. Frequently also, there exists extreme sensitiveness of the skin, the slightest touch provoking a typical nervous crisis. Further, the pain is superficial, whereas in true coxalgia it is deep-seated. The muscular contractions in pseudo-coxalgia are resistant, contrarily to what obtains in the true form, where they can be surmounted with a little patience in provoking certain movements of the joint. Locomotion in both affections presents characteristic signs. In coxo-tuberculosis, the patient suffers agony from the slightest attempt at walking, and will refuse to leave the bed, while the hysterical patient will limp

about readily enough and does not complain of pain. This is an important sign and should be borne in mind.

Except in rare cases, and remembering the symptoms I have just mentioned, you will be able to diagnose hysterical coxalgia without difficulty. You will take into account the *début*, generally sudden; the attitude, flexion, adduction and rotation inwards; the inconstancy of the seat of pain and its superficial character. Besides, muscular atrophy, which is one of the most important signs of tuberculous coxalgia, is usually absent, and there is no fever.

The prognosis of hysterical coxalgia is in most cases benign. The affection is always recovered from, often spontaneously, but you must not forget that it is liable to return on the slightest cause.

In what does the treatment consist? Everything has been tried from most rational to most empirical therapeutics, and frequently the patient recovers after all treatment has been abandoned. Charcot insisted on the necessity of renouncing all violent measures from a surgical point of view, and of treating the affection by bromides and general nerve sedatives, and especially by those means which appeal strongly to the imagination, such as magnetism, hypnotism, suggestion.

I quite agree with this advice as long as the limb has not assumed an abnormal position. If the contrary be the case, however, it will be necessary to correct the attitude under chloroform, and maintain the position thus obtained by some suitable apparatus.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, JANUARY 10TH.

The President, Dr. BUZZARD, in the Chair.

FOUR CASES OF MOVABLE KIDNEY.

Dr. DAVID NEWMAN (Glasgow) described four cases of movable kidney, in two of which he performed nephrorrhaphy for the cure of transitory hydronephrosis, and other two cases in which the same operation was resorted to for the relief of torsion of the renal blood-vessels, causing albuminuria and the presence of tube-casts in the urine. *Case 1.*—Transitory hydronephrosis and slight albuminuria during paroxysmal attacks of pain. When first seen patient had developed all the characteristic symptoms and physical signs of movable kidney. Paroxysmal attacks, at first occasional, afterwards frequent and sudden. Such paroxysms sometimes lasted as long as 28 hours, during which time as much as 36 ozs. of urine accumulated in the renal pelvis; when it escaped the pain passed away slowly. *Case 2.*—Right movable kidney, with transitory hydronephrosis from kinking of the ureter, no albuminuria. Operation—cure. The hydronephrosis was seldom absent for more than a few days, and was sometimes distended to contain 40 ounces of urine. *Case 3.*—Right movable kidney, causing torsion of the ureter, and leading to hydronephrosis, albuminuria, and the presence of tube casts in urine. With the onset of the paroxysms of pain sometimes there was present hydronephrosis: sometimes it was absent or not observable, but high specific gravity of the urine, and albuminuria and tube casts always appeared in the urine at the same time as the pain. Since operation no albumen or tube casts have been found. *Case 4.*—Left movable kidney, causing torsion of renal blood-vessels, albuminuria, tube casts, severe pain and suppression of urine. No hydronephrosis. Operation; cure. The kidney was only freely movable, but no increase in size could at any time be made out. In cases of transitory hydronephrosis the usual course of events is a sudden suppression of urine, almost immediately followed by paroxysms of severe pain, which continue and steadily increase in severity until suddenly relieved by the passage of a copious flow of dilute urine. Sometimes the urine is free from albumen, in other instances a trace or even a considerable amount of albumen may be found to

be present. This albuminuria usually disappears within a few hours. During the attack the patient is generally compelled to go to bed, but is seldom able to occupy the recumbent position, preferring rather to sit up with the knees flexed over the abdomen, and the chest thrown well forward. This position is assumed for the purpose of relieving the abdominal pressure. In cases of torsion of the renal blood-vessels the pain is equally severe during the whole period of attack. There is little or no increased swelling in the renal region. In transitory hydronephrosis the relief of pain is coincident with the sudden flow of a large quantity of dilute urine, whereas in torsion of the renal blood-vessels the termination of the paroxysms is accompanied by the escape of a comparatively small quantity of concentrated urine. One of the most difficult points to explain is the presence of tube-casts. The generally accepted opinion is that the presence of tube-casts in the urine indicates the existence of an inflammatory lesion in the kidney, but in the cases shown the tube-casts were caused by a mechanical hyperæmia.

Mr. BRUCE CLARKE said the author had raised two points of considerable interest, one being the frequent presence in the urine of albumen and tube-casts, and the other the method of suture. A certain amount of albumen was usually found in the urine in cases of hydronephrosis. Though transient this was fairly constant. In nephrorrhaphy it had never been his practice to pack the wounds with gauze. Nevertheless, in the cases in which nephrectomy had afterwards been required, he had found great difficulty in removing the kidney, so firmly was it fixed. In performing nephrorrhaphy he cut through the capsule, excoiating the renal substance by several scratches with the knife, and then fixed the organ by two or three sutures passed through the kidney substance. He congratulated the author upon the excellence of his results in the presence of such a great degree of antecedent nephrosis. He himself had not succeeded so well in cases of large hydronephrosis, but he did not fix the kidney as high up.

Dr. NEWMAN, in reply, said his paper dealt rather with cases of occasional hydronephrosis, than with cases in which the hydronephrosis was constantly present, these being only occasionally relieved. In the latter cases the kidney was usually diseased and albumen was consequently present in the urine. In the cases of occasional hydronephrosis, on the other hand, the presence of albumen and tube-casts in the urine was more difficult to explain. He asked why indeed should transient passive hyperæmia lead to the presence of tube-casts, the occurrence of which physicians were in the habit of regarding as of grave import, and as an indication of inflammatory trouble. The principal points in the operation were to fix the kidney as high up as possible, and to fix it firmly, and in doing this to get away as much of the adipose capsule as possible.

Mr. LEE DICKINSON ON

SPONTANEOUS THROMBOSIS OF THE CEREBRAL VEINS AND SINUSES IN CHLOROSIS.

Three fatal cases in chlorotic young women were described and others were referred to. Thrombosis of this kind, as an event of clinical importance, he pointed out, occurs more often in chlorosis than in any other one disease. That chlorotic blood is morbidly prone to coagulate within the vessels is evident from the frequency with which it does so in the veins of the lower extremities. In one of the cases described a pneumonic state of part of one lung was found post-mortem, a thing worth remarking, because in pneumonia the blood is highly fibrinous and coagulation in the right heart a recognised danger. Sinus-thrombosis, however, is very rare in pneumonia, and of 367 cases of pneumonia observed by the author, other forms of venous thrombosis occurred in only seven. Of these seven, four were young women, and two were chlorotic. The distribution of intravascular coagulation brought about in animals by injection of foreign substances into the circulation is largely determined by the amount of carbonic acid in the blood. Chlorotic blood is probably overloaded with carbonic acid. The comparative infrequency of thrombosis in the sinuses, where the mechanical conditions are so favourable, may be explained by the recent observation that the cerebral venous blood is but slightly carbonised. The lesser degrees of sinus-thrombosis are not always

fatal, and are, perhaps, less rare than is supposed. In some recorded cases of optic neuritis as a complication of non-fatal chlorosis the severity of the headache was out of all proportion to the degree of anæmia. Optic neuritis and severe headache are the two most prominent symptoms of sinus-thrombosis. A fourth fatal case is described in a young but not chlorotic woman. The thrombosis was limited to the veins Galeni and their tributaries.

Sir DYCE DUCKWORTH said his attention had been called 25 years since to a typical case of the kind, and since that time he had taken considerable interest in the subject. He related the case of a young woman who presented all the ordinary aspects of chlorosis, with very severe and distressing headache. The case ended fatally, and post-mortem they found it to be an excellent example of thrombosis of the cerebral sinuses. Since then he had looked out in all cases of severe chlorosis in women for the occurrence of severe rebellious headache as possibly indicating the onset of such a condition. He did not, however, meet with another case until some three years ago. The patient was a woman, æt. 35, who came in about three weeks after her confinement, looking very ill, and suffering from white leg, due, no doubt, to thrombosis of the corresponding femoral vein. In like manner she had severe and torturing headache, along with optic neuritis and slight convulsive attacks. He made the diagnosis of thrombosis of the cerebral sinuses, basing his diagnosis on the severe headache, the profound anæmia, and the optic neuritis, together with the convulsive movements.

Dr. SPURBELL recalled a case which came under his notice 12 months ago, the patient being a girl, 13 years of age who was admitted with a diagnosis of scarlet fever which however, proved to be erroneous. She complained of great pain in the head and the temperature rose to 104° and 105° F. There was some rigidity of the neck and retraction. She had been taken ill three or four days previously to admission, and gradually got worse, became comatose, the pupils being equally dilated but not reacting to light. The existence of optic neuritis was doubtful. She died at the end of a week and post-mortem the cerebro-spinal fluid was found to be greatly in excess, the right optic thalamus was much enlarged, the choroid plexus was covered with a thick film of fibrinous exudation and the right vein of Galen and the great vein of Galen behind were occupied by clot projecting 1-10th of an inch into the great sinus. The optic thalamus had undergone white softening throughout. The child was anæmic but not markedly so and there was no heart disease.

The PRESIDENT said the cases so far narrated appeared without exception to have had a fatal termination. It happened, however, that he had in hospital at the present time a girl, æt. 13, who was admitted a month since with symptoms pointing to this affection. She was however, at present on the road to recovery. Her history was that after having had a good deal of pain in both sides of the face for 12 months she was taken two months ago with a series of screaming fits followed by loss of consciousness for several hours. She also complained of intense headache. Three weeks before admission, her right lower extremity swelled up to twice the size of the other. She was markedly chlorotic and could scarcely stand or walk, although there was no definite paralysis. She presented double optic neuritis. On examining the blood, the proportion of hæmoglobin was found to be reduced by 50 per cent. She was put upon iron immediately, and at once began to improve. He suggested that they ought to bear in mind that cases might occur in which the symptoms were less pronounced, and these minor cases were far more likely to come under their notice. He had no doubt that many such cases curring in young women were put down to simple hysteria.

Dr. DICKINSON, in reply, said a somewhat similar case had been reported by Dr. Bristowe, in which the patient was also exceedingly hysterical.

ADDISON'S DISEASE TREATED WITH SUPRA-RENAL EXTRACT.

Dr. SYDNEY RINGEE and Dr. ARTHUR PHEAR contributed an account of a case of Addison's disease treated with supra-renal extract, and also gave a brief résumé of recorded cases for which similar treatment had been adopted. It appeared that of nine cases, five had shown improvement, although in some of these a sufficient time had not elapsed to determine whether or not the benefit

was permanent. In two cases no improvement was noted; in one case the treatment was given only a very limited trial; in one the disease ended fatally in spite of supra-renal treatment. The supra-renal tissue was in some cases administered by the mouth, in other cases hypodermically. Details were then given of a case lately under this treatment in University College Hospital. A woman, *æt.* 28, had been suffering from symptoms of Addison's disease for a period of two years, progressive weakness with some loss of flesh, vomiting without special relation to food, and pigmentation of the skin. Excessive pigment was present on the face, hands, forearms, axilla, about the nipple, over the knee-cap, and in the neighbourhood of the toes and ankles. The discolouration was well marked in the armpits and around the mouth. There were deeply pigmented inky patches on the mucous membrane of the mouth, opposite the teeth. There was no evidence of tubercle in the lungs or elsewhere. Treatment with supra-renal extract was commenced, in doses equivalent to 45 grains of suprarenal body daily; this was gradually increased to a daily dose of 120 grains. There rapidly followed improvement in the general condition, and the pigmentation became notably lessened in degree. Vomiting, however, remained troublesome. No rise of arterial tension was noted. The improvement continued for four weeks, when there was a rapid change for the worse. There was no increase of pigmentation, but the general condition quickly deteriorated, cardiac action became feeble, and death occurred within six weeks of the commencement of the treatment, and just over two years from the earliest symptoms of the disease. The temperature rose to 102 degrees on the day before death. During the last few days arsenic and strychnine were given in the place of the supra-renal extract. The autopsy showed the supra-renal bodies to be shrunken and flattened about a third of their normal size, and exhibiting no trace of the normal structure.

Dr. PARKINSON related a case recently admitted to the Westminster Hospital under Dr. Murrell, in which the treatment by supra-renal gland was tried. The patient was a man, *æt.* 31, who for three months past had been complaining of weakness and bronzing of the skin. He presented no signs of phthisis. The treatment with extract (5 grains) was begun on November 26th. Twelve days later he began to vomit rather frequently. He was then given fresh sheep's gland in doses of one drachm three times a day, after which the vomiting increased in severity. The dose was then reduced to 15 grains thrice daily, and the vomiting diminished. The patient gradually sank and died, and post-mortem they found the usual caseation and enlargement of the supra-renal glands.

Dr. TURNER related the case of a young man who had had an attack of syncope. There was slight pigmentation but it was quite enough to make sure of the diagnosis, being particularly marked on the backs of the hands. He was given a glycerine extract of supra-renal gland, equal to a third of a gland, a day, but he only lived about a fortnight after the treatment had been begun, and no definite result was obtained. Vomiting however, became a prominent symptom. Post-mortem both supra-renal capsules were found to be caseous. The last case of the kind in which the treatment had been tried died two days after admission when he had only received four doses, so that it could not be said to throw any light upon the effects of the treatment.

Dr. HALE WHITE said they had had an experience of the treatment in a patient who was treated for Addison's disease because it was at first thought he had it. They noticed that he invariably got a temperature of about 102 degrees Fahrenheit after the administration of the drug, which subsided when it was discontinued. It was discontinued when it was noticed that he was passing the dark urine, rich in iron, characteristic of pernicious *æmia*, from which he proved to be suffering.

Dr. RINGER in reply, pointed out that Addison's disease notoriously ran a very variable course, so that an experience of one case could not go far in deciding the value of the treatment or otherwise.

Dr. PHAR in reply, said he did not think the vomiting in this case was due to the treatment, because it was equally well marked before it was begun. The patient's temperature was normal throughout, except immediately before death.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

MEETING HELD FRIDAY, DEC. 20TH.

The President, Dr. LOMBE ATTHILL, in the Chair.

SPECIMENS EXHIBITED.

Dr. ALFRED SMITH showed the following specimens:—

(1) An abscess of the ovary with pyosalpinx, which he removed from a patient who suffered from a severe attack of puerperal fever, twelve months previously; ovarian abscess burst during removal; contents particularly fetid. Peritoneal cavity was protected by thin gauze sponges: pelvis douched out with gallons of saline solution; drainage; rapid recovery. (2) A large multilocular ovarian tumour, with extremely extensive adhesions. The entire cyst-wall was intimately adherent all round, and in the lower zone coils of small intestine were embedded in its walls, and could only be separated by dissection at the expense of the cyst, taking care to remove the cellular layer. There was extensive hæmorrhage after separation of the adhesions from the abdominal wall, easily controlled by the purse-string suture; douched with saline solution; drainage; recovery. (3) A pair of tubes and ovaries removed from a patient, *æt.* 28, who had a multinodular fibro-myomatous uterus, and suffered from severe hæmorrhage. The outlet of the pelvis was very contracted, and not favourable for morcellation.

Dr. MACAN exhibited (1) a case of hysterectomy done for a large fibroid; (2) a vaginal polypus; and (3) uterine fibroid polypus.

Dr. HASTINGS TWEDDY exhibited a dermoid tumour of right ovary, which he removed from a patient, aged forty-five years. The woman only noticed the abdomen enlarging for three months previous to operation, during which time she suffered intense pain. The cyst extended above the umbilicus for two inches. The patient made an afebrile recovery. The tumour is an interesting one, not alone on account of its large size, but also from the fact that it contains much hair and a portion of lower jaw, with many teeth embedded in it. He also showed a cyst of left ovary, which he had removed from a woman, aged twenty-five, who had had two children, the last seven weeks previous to operation. According to the patient's statement, the tumour had increased enormously in size since the birth of her last child, and was accompanied by great pain. Dense adhesions made the operation difficult, necessitating in one spot the leaving behind a piece of the tumour wall attached to the intestine. The patient made a rapid and uneventful recovery. He also showed a very large sub-mucous myoma, which had almost become a polypus, and was in a sloughing condition on its outer surface. The patient had suffered for seven months from great pain and a fetid discharge. The tumour completely occluded the vagina, and weighed over 2 lbs. In consequence of its great bulk, it was quite impossible to reach its base. He removed the tumour piecemeal by means of Dr. W. Smyly's spoon forceps and stout scissors, without the exhibition of force, or any injury to the soft parts. The patient made a rapid recovery.

AN INTERESTING SOLID OVARIAN TUMOUR.

Dr. ALFRED SMITH read a paper on an interesting solid ovarian tumour. The patient, aged twenty-five, unmarried, was admitted on Oct. 1st, to the gynaecological wards of St. Vincent's Hospital. She was unable to recline on the bed, so enormously distended was the abdomen. She had to be supported in the semi-erect position by an arrangement of pillows, any attempt to lie down on the bed caused intense dyspnoea. Abdominal palpation revealed an immense collection of free ascitic fluid, and no tumour could be made out. Vaginal examination gave negative results. In consultation with Dr. M'Hugh, a diagnosis was made of ascites, from portal obstruction. Patient was removed to medical ward, and paracentesis was performed, removing fourteen pints of thin, serous fluid. A tumour occupying the left inguinal and lumbar regions was then distinctly palpable, it floated freely about the abdominal cavity, its range of motion being very remarkable; it touched the ribs easily on either side. The diagnosis was made of long-pedunculated, solid ovarian.

Ascites returned very quickly after tapping, and distension became again enormous. Tumour was removed by oeliotomy; the pedicle was very broad and vascular, was ligatured by the inter-locking chain suture. Patient's recovery was interrupted by a severe internal hemorrhage, which took place thirty-six hours after operation, which was controlled by re-opening the abdomen and securing the bleeding vessel. The blanched and pulseless condition of the patient required the use of saline solution as a peritoneal douche. This caused a marked and immediate improvement; no drainage; recovery slow. There has been no return of the ascites since the operation, now seven weeks ago. The points of special interest for discussion were—(1) the cause of the ascites, (2) the cause of the hemorrhage, (3) the value of immediate operation, and (4) the prognosis.

A pathological examination of specimen by Professor M'Wesney revealed the tumour to be a myo-sarcoma, its size that of the adult head.

PAPER ON OVARICTOMY.

This paper, by Dr. R. J. KINKRAD, was read for him by the Hon. Sec. It enumerated the details of an interesting ovariectomy performed on a patient, *æt.* 60. There were extensive adhesions to abdominal wall, and the omentum was adherent so firmly that the adhesion had to be double ligatured and then cut between the ligatures. The pedicle was very short—so short that a portion had to be dissected from outer surface of the tumour to form a stump. The pedicle was rotated and had to be twice turned completely round from right to left to untwist it. Wound closed by interrupted sutures passed through entire thickness of abdominal wall. Wound healed by first intention; patient sat up in bed on the 10th day, was out of bed on the 18th day. The cyst contained 640 ozs. of dark-brown fluid. There were many smaller cysts inside parent cyst; it was described as an unilocular oöphoritic cyst.

MULTILOCLAR OVARIAN TUMOUR.

Mr. HENRY GRAY CROLY exhibited a large multilocular ovarian tumour which he removed from a girl, *æt.* 16, in the City of Dublin Hospital, on July 2nd, 1895. The tumour commenced to grow about nine months before her admission to hospital, and was first observed on the right side. The abdomen was very large, and numerous veins ramified over the tumour. The fluctuation was very distinct, high in the abdomen—less so towards the pelvis, where solid masses were felt. Menstruation was irregular of late, and the "ovarian face" was very marked. The girl lost flesh considerably. The measurements were 38 inches in circumference at level of umbilicus, 30½ inches at ensiform cartilage, 8½ inches from umbilicus to right anterior superior spine, 8½ inches from ensiform cartilage to left anterior superior spine. The usual incision was made, and Mr. Croly found it necessary to prolong the incision upwards and to the left of the umbilicus. A very large and distended vein in the broad ligament lay across the upper part of the cyst. The vein was secured by double sterilised silk ligature, and divided between them. Two gallons of gelatinous, greenish fluid were drawn from the large cyst which Mr. Croly then opened, when several more solid tumours were found, and are well seen in the specimen now on the table. Mr. Croly found some difficulty in removing the tumour from the pelvis. This was caused by the locking of the smaller cysts in the pelvis. These cysts were opened with a scalpel and by finger, and a boiled starch substance escaped. The pedicle was tied in the usual way, and no drainage was adopted. There was no hæmorrhage. The girl was fed "per rectum" for several days, and made a rapid recovery and got fat. She returned to the country, and is in perfect health.

MISPLACED AND ROTATED SPLEEN WHICH SIMULATED AN OVARIAN TUMOUR.

Mr. HENRY GRAY CROLY exhibited a spleen, which he removed from a married woman, *æt.* 40, in the City of Dublin Hospital, on December 7th. The woman had had several children; but never noticed any abnormal tumour until last summer. The swelling commenced at the left side, and gradually extended towards the right; was not painful. She lost flesh and her features changed. She thought at first she was pregnant. The doctor who attended her previously never observed any abdominal

tumour until he was consulted after her last confinement. She aborted shortly after her admission to hospital. On palpation the tumour was firm, and gave the sensation of fluctuation, and, though apparently larger on the left side, crossed well over to the right, and could not be moved upwards or downwards. There was no history of ague, and the woman was never out of her native place. The usual vaginal and uterine examinations were made by the skilled gynecologists to the hospital and the distinguished Master of the Rotunda Hospital. When the patient was first admitted to hospital no decided opinion was expressed beyond that it was an "abdominal tumour," and no clinique was given, but the case was carefully palpated, and attention paid to improving the lowered condition of the patient's health. She was well fed, and allowed into fresh air, and walked as much as she felt inclined or equal to. After the final examination of the tumour by the gynecologists, the unanimous opinion expressed was the belief of its being ovarian. The question of the difficulty of diagnosis of abdominal tumours of all sorts is well known, and this proved no exception, and, though doubts were at first expressed on the case, all at the final examination believed the case to be ovarian. Mr. Croly performed laparotomy, and came down on a large, solid, fleshy mass, with purpuric mottling on the surface. The small intestines were adherent to and fixed by the tumour, but were freed by the fingers. There was no hæmorrhage; as the mass was firmly fixed and could not be raised, the pedicle was sought for in the usual position but not found; the wound was then extended above and to the left of the umbilicus, where a funis-like pedicle was discovered, feeling like a bar of iron. This was surrounded by omentum. The hand was now passed along the pedicle and the spleen space was empty. The pedicle was secured by a stout double-silk ligature (sterilised). On section, the mouths of vessels were seen as in an "Esmarched limb." There was no blood lost; no vessel required ligation, torsion or clip. The peritoneal cavity and pouches were sponged. The abdomen was not closed until all risk of bleeding points was made certain. The patient bore the anæsthetic and operation, which was rapidly done, well, and went on most favourably for some days, when vomiting set in (of a greenish fluid), and symptoms of collapse, and she succumbed. No post-mortem examination was obtained.

The following discussion took place on the three papers:—

Dr. TWEEDY remarked that Dr. Smith, in his paper, said nothing about having examined the second ovary. Sarcomatous tumours occurred, as a rule, in both ovaries; here sarcoma only occurred in one. He was not quite clear that Dr. Smith's case was one of ordinary sarcoma. Referring to Dr. Croly's case, he said that unless the pedicle could be felt no certain—at least only an approximate—diagnosis could be made.

The PRESIDENT said, that Dr. Smith's paper put him in mind of a case that came under his care fifteen years ago. She had what he diagnosed to be an ovarian tumour with ascites. After opening the abdomen it became so wedged in the brim of the pelvis that he could not well get it out, and it was so soft that it broke down. One of his assistants had to force the tumour up from the vagina before he could remove it. It proved to be a sarcoma. She is now married, and her only cause of regret is that she has no children. He asked Mr. Knowsley Thornton his experience, and he was of opinion that, without exception, in every case in which the disease had occurred, the patient died within twelve months. His case was important, inasmuch as it proved that sarcoma of the ovary was not necessarily fatal and that only one ovary may be affected. In the absence of malignant disease there must be some constitutional cause of the ascites. When he (the President) was a student, some twenty years ago, Dr. Stokes laid it down as a law that if ascites were present the disease was most likely malignant, and he (the President) thought that law held good at the present day.

Dr. GLENN said that in differentiating between an ovarian and splenic tumour, the points to be relied on were—(1) the presence of a notch; (2) the consistency of the tumour; (3) and its position.

Dr. MACAN could not see why Dr. Smith did not make his diagnosis himself instead of handing the case over to

his medical colleague. He thought another diagnosis might have been made, and that there was another cause for the ascites, that was tubercle. He had opened an abdomen himself and found not a trace of fluid, where there was no doubt that the disease was carcinomatous. He congratulated Dr. Smith on his paper. He could not gather the evidence on which it was stated that the spleen was likely to suppurate in Mr. Croly's case. His diagnosis of the case was that the woman had been going about with a twisted spleen for many months, and that enlargement was due to the twist.

Dr. LANE, speaking of the tumour, said Mr. Croly referred to pregnancy. He asked the patient was she pregnant and she said no. He was under the impression that it was a fibro-cystic tumour. On examination, per vaginam, he found the cervix softer and more congested than is the case in pregnancy. The uterus was also more increased in size than it would be in pregnancy. To his mind it had a very elastic and fluctuating feel. When the abdomen was opened the tumour had gone up to the diaphragm, and it seemed that the pedicle was going down into the pelvis, and that it was not going upwards towards the left side.

Mr. M'ARDLE congratulated Dr. Smith. He mentioned three cases of sudden hæmorrhage. One was from a friable pedicle. In all three cases referred to the rapidity with which the pulse returned was well-marked after injection of saline solution. At the time they were securing the bleeding points the patient was blanched, and large beads of perspiration stood on the forehead. The shock that was often spoken of in connection with these operations meant often that inflammation had spread along the pelvic veins. He was acquainted with two cases where death was attributed to shock; but the fact was, in each case, a cast of the inferior vena cava was found in the right side of the heart. He believed the use of the clamp forceps set up phlebitis, and was a cause of the high mortality in those operations. He pointed out the advantage of digital pressure practised in a manner shown. In the diagnosis of abdominal tumours he laid stress on elevating the patient in the Trendelenberg position. Unless the tumour was adherent to the rectum it would move upwards towards the diaphragm. He thought thrombosis of the splenic vein accounted for the hard cord.

Dr. WINFRED DICKSON mentioned a case in which there was ascites, yet the case was an ordinary cyst. Dr. Dickson mentioned the fact, as a good deal had been said as regards ascites accompanying malignancy.

Dr. HORNE said, when they were examining the case, they were struck by the amount of ascites present. With regard to the bleeding occurring 36 hours after the operation, they should remember that Dr. Smith pointed out that the pedicle was very broad—it measured 5 inches in breadth. He connected the bleeding with the vomiting. He also made some remarks on the histological character of the tumour.

Dr. SMITH, in reply to the remarks made on his paper, said he could give no explanation of the ascites. The fact that Dr. Atthill's case is still living gave him hope. He did not clearly understand what Dr. Atthill meant by saying the cause of the ascites in his (Dr. Smith's) case was constitutional. He commented on Dr. Macan's view as to the tubercular nature of the disease.

Mr. CROLY replied to the observations of Dr. Macan and other members. He could not agree with Mr. M'Arde as to the value of turning the patient upside down, seeing that the tumour was adherent in all directions.

The Section then adjourned.

WEST-LONDON MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD FRIDAY, JANUARY 3RD, 1896.

A. SYMONS ECOLES, M.B., President, in the Chair.

THE DIAGNOSIS OF GONORRHOICAL INFLAMMATIONS.

Dr. FREDERICK JOHN McCANN, read a paper on this subject, in which he described in detail the method of obtaining pus. He recommended fuchsin as the best staining reagent for the gonococcus, and eosin and methylene blue for contrast stains. The appearance of the gonococcus

under the microscope was detailed. The relation of the gonococcus to the pus and epithelial cells was narrated and demonstrated by photo-micrographs. A gradual process of pus cell destruction had been traced which was partly antagonistic to the theory of Metchnikoff. The same destructive process was seen in epithelial cells. The author emphasised the fact that a large number of gonococci is never seen in conjunction with a large number of pus organisms. He offered the following propositions: (1) Gonococci are present in the pus of every untreated case at some period. (2) Secretion free from gonococci does not cause a gonorrhoeal inflammation. (3) Secretion containing gonococci even in small quantities affects sensitive mucosa with absolute certainty. He insisted on systematic examination of the pus in all cases of supposed gonorrhoea, and referred to the medico-legal aspects of Neisser's discovery. The seats of gonorrhoeal inflammation, and the reasons for the special positions were given. The pathology of inflammation of the Fallopian tubes was next discussed. The concluding remarks were devoted to the cultivation test.

The PRESIDENT said that in his experience there was not much hope of dealing successfully with gonorrhoeal arthritis while gonococci lurked in the urethral discharge.

Mr. McADAM ECOLES remarked on the uncertainties of diagnosis by means of the microscope, and the difficulty of making cultivations.

Mr. LLOYD quoted a case of gonorrhoeal arthritis which was followed by pyæmia and an early fatal issue.

Mr. KEETLEY thought many rheumatoid cases, both in men and women, were of gonorrhoeal origin, in which no history of infection could be got. The complications of gonorrhoea in women were a great source of mental, as well as physical suffering, and of moral degradation. Owing to the difficulty of cure, we ought to do our utmost to prevent this virginal infection.

Dr. McCANN, in reply, said that though regarding most cases of gonorrhoeal arthritis as pyæmic, yet, since such good observers as Neisser had found gonococci in the pus joints in these cases, he was bound to admit that certain proportions were caused by the gonococcus.

Dr. CLEMOW, in some observations upon the

TREATMENT OF ENTEROCOLITIS IN INFANTS AND YOUNG CHILDREN,

drew attention first, to the undoubted bacterial origin of the disease. Upon the recognition of this depended the adoption of rational methods of treatment, the indications for which were—(1) to evacuate the intestines of their fermenting contents; (2) to combat the processes of decomposition by appropriate drugs; (3) to administer such food to the child as shall be best calculated to maintain its strength, and of such a nature as to minimise the introduction of fresh micro-organisms, and least favourable, therefore, to a furtherance of the processes of decomposition; (4) to treat symptoms and complications as they may arise. As regards antiseptic drugs, he considered the subnitrate of bismuth and mercurials, especially calomel, as the most trustworthy, and deprecated the general use of astringents and opiates. He had been much impressed with the value, in certain cases, of intestinal irrigation, with regard to the employment of which he had formed the following conclusions:—1. The operation exercises no influence upon the course of tuberculous ulceration of the intestine. 2. It is probably of little or no benefit in the ordinary cases of dyspeptic diarrhoea of infants, where the small intestine is wholly or mainly affected. 3. It may be expected to exercise a beneficial influence upon the course of the disease in general cases of enterocolitis, and especially in those in which the colon is largely involved. 4. It requires to be carried out with great caution, and more especially so in those cases in which there is considerable prostration.

Dr. COLMAN referred to the possibility of accidents in irrigation and their prevention. From post-mortem experiments it appeared that in softened states of the colon, two feet was a safe level to which the can might be elevated.

Mr. McADAM ECOLES cited two cases in which rupture of the gut had occurred when the operation had been performed for invagination.

The PRESIDENT held that in these cases, milk in any

form should be excluded from the dietary for twenty-four hours. He said that in catarrhal conditions of the small intestine, with much acidity, salol would be inert since it is insoluble in such a medium. He prescribed irrigation in colitis, and laid stress on the value of cinnamon water as an antiseptic. The inflow might be observed by ausculto-percussion.

Dr. CLEWELL replied.

Mr. STEPHEN PAGET exhibited a specimen of carcinoma of the œsophagus with perforation of the posterior wall of the trachea.

SOUTH-WEST LONDON MEDICAL SOCIETY.

MEETING HELD JANUARY 8TH.

Dr. GILBERT RICHARDSON in the Chair.

THE meeting was held at Windmill House, Clapham Common, by the kind permission of Dr. Benjamin Duke.

A paper on

PROFESSIONAL UNIONISM

was read by Mr. W. G. DICKINSON, and was followed by a discussion, in the course of which

Mr. T. A. G. BOWELL referred to the difficulties which surround the whole question, and pointed out that local medical societies fail to attract men who are bringing discredit on the profession.

Dr. MORGAN DOCKRELL alluded to cheap practice and underselling, and stated the root of the evil to be that the supply of medical men is greater than the demand; he thought that means should be taken to check the influx of medical students, and of educating them in medical ethics; he further alluded to the necessity for reforming the British Medical Association.

Dr. ROE and Dr. BARKWELL referred to the touting of insurance company and dispensary agents, and

Mr. A. E. DOBSON mentioned the evils of the out-patient system, and the lay medical aid societies, at the same time expressing sympathy with the difficulties of those commencing practice.

Mr. DICKINSON having briefly replied,

The meeting terminated with a hearty vote of thanks to Dr. Duke for the use of his house.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, Jan. 11, 1896.

OPERATIVE TREATMENT OF PROGRESSIVE MYOPIA.

At the last meeting of the Académie de Médecine M. E. Valude read a paper on this subject. He pointed out that when myopia becomes extreme, and particularly when it assumes a progressive form, the ordinary means of combating it are often quite powerless. Rest (and even certain operations such as tenotomy, rarely serve to stay the advance of the malady, and glasses are, as a rule, insufficient to improve vision owing to increase in the defect of refraction. Many patients are thus almost entirely prevented from following occupations demanding eyesight. In these conditions M. Valude strongly advocates extraction of the crystalline lens, an operation which has come to the front of late years, believing it produces the happiest results, since by removal of the lens refraction of a very myopic eye is brought back nearly to emmetropia. If, especially in France, a large number of surgeons are not too fond of this operation, it is, perhaps, because the indications for it have not been sufficiently well defined, and because so many dangers surround operative interference with an organ so delicate as an eye afflicted with extreme myopia.

M. Valude related two cases which illustrated the safety which might be secured to the operation and the excellent results which might be achieved.

The first was a man, æt. 35, affected with progressive myopia such that he could not read at any distance ordinary characters, and counted fingers at 0.50 centimetres. M. Valude extracted the crystalline lens of both eyes, and the patient was able to read the smallest type at 0.30 centimetres. This man is at present employed in the laboratory at the Salpêtrière Hospital. He can see at a distance without glasses. The operation was done two years ago.

The second case, a farm servant, was almost identical with the first, and like it was not caused by close use of the eyes. The malady had advanced rapidly and prevented him from following his avocation. Glasses did not help him, and he counted fingers on one side at one metre, on the other at 0.60 centimetres. Double extraction was performed, with the result that he was enabled to read small type with convex glasses; and for distance with weak concave glasses his vision was sufficiently good.

Operative treatment of progressive myopia is thus shown to be desirable treatment in certain cases where other measures fail; and if proper precautions be observed M. Valude believes that the dangers to the eye from the operation are not sufficient to deter the surgeon from undertaking it.

SCARLATINA.

At the Société des Hôpitaux M. Lemoine spoke on the period of contagion of scarlatina which is commonly assigned to the termination of the malady, that is to say, when desquamation sets in. For him that idea is erroneous, he places it, on the contrary, at the *début*, and ascribes the seat of it to the mouth and pharynx, from which the skin, the clothes, and every object surrounding the patient is infected. For this reason the speaker considered that disinfection of these cavities should take the first rank amongst prophylactic measures, by which also the isolation at present so prolonged of patients suffering from scarlatina can be shortened considerably.

M. Legendre agreed with his colleague in placing the contagion at the first period of the malady, but was a partisan of prolonged isolation.

The view taken by M. Lemoine is important, being very probable, and perhaps in other eruptive affections, as measles and small-pox, the specific agents of which are still unknown, the contagion arises from the same source, the mouth and the pharynx. It seems consequently to be rational treatment to disinfect these parts, rendering thus a double service, the first to the patient, the second to the attendants.

DISINFECTION OF THE MOUTH.

- R Salicylic acid, xx grs.;

LOCALISED NEURALGIA.

- R Menthol, xxx grs.;
- Guaicool, xxx grs.;
- Proof spirit, ʒj.

Paint the parts twice a day.

QUACKERY in America has taken the form of "laying on of hands." It is doubtful, however, whether this will become very popular, because so many other persons can play at the game—and one is quite enough, if he happens to be a police officer—as has been proved in several instances.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, Jan. 10th.

At the meeting of the Society for *Innere Medizin*, Hr. Schwalbe related a case of

RUPTURE OF THE HEART.

The case was that of a man, *æt.* 56, who consulted him in March of last year, on account of breathlessness and palpitation. Examination revealed emphysema and considerable dilatation of the heart on the left, and a systolic murmur over the aorta. The pulse was regular and not accelerated, slight dulness at the apices of both lungs. Thirty years ago the patient had syphilis, but had been in good health since. He was married and his children were healthy, and his wife had never aborted. He was a fairly free drinker of wine as he was agent for a wine house. Four weeks before seeking advice he had hæmoptysis with copious expectoration of dark-coloured blood. A diagnosis of stenosis of the aorta from arterio-sclerotic was made. In April and July the patient had serious attacks of serous pleuritis with a good deal of exudation, but this was absorbed. The speaker thought salicylate of soda was very useful on this occasion. *Digitalis* also was useful. On Dec. 6th he had an attack of *angina pectoris* that lasted eight hours, during which the patient became collapsed and cyanotic, but from which he recovered. On Dec. 15th he died suddenly whilst walking across the room. The autopsy showed that the heart was two and a half times the normal size, and weighed five pounds. It was extensively covered by emphysematous lung tissue, so that the dulness on percussion did not correspond to the size of the heart. The pericardium contained about ten table-spoonfuls of dark clotted blood; the apex of the greatly dilated left ventricle was the site of a rent 3 centimetres in length; the aortic valves were sclerosed, and two of them grown together.

Herr Mendelsobn then gave an address on

CYCLING AND ITS INFLUENCE ON HEALTH.

As regarded the muscles, two groups came into consideration, first that used for pedaling, and that for keeping the body erect. The working of the pedals might be compared to the action of mounting steps whilst in the sitting posture, the actual work lay in the downward movement, in which all the extensors of the leg came into play. The flexors were only moderately exercised. For maintenance of the position the muscles of the trunk, and especially those of the arms, were called into exercise, and this constantly. In consequence of this these muscles soon became tired, especially in beginners, and hypertrophy of them took place. The extensors of the lower extremities especially became hypertrophied. To a less extent the muscles of the arms and shoulders also enlarged, but in this case it was the flexors and not the extensors.

As regarded tissue changes, the urea was considerably increased, but the excretion gradually returned to the normal in spite of continued excretion. The excretion of uric acid increased at first, but sank again to the medium amount.

The appetite and thirst were increased. Before commencing the exercise it was not well to eat too much, as the body bent forward pressed on the stomach, and again during the exercise much less gastric juice was secreted. Assimilation and defecation were favourably influenced. Hæmorrhoids, however, developed by immoderate exercise.

Dyspnoea was set up by exhaustion of the respiration and the heart. Above all things an art in breathing was necessary, the breathing should be deeper but not more frequent. It was also advisable to breathe through the nose as then the expired air from the lungs had not to overcome the heightened pressure produced by the rapid movement. The more the head was bent downwards, the better the air passing through the nose took the direction of the opposite streaming outside current.

The heart's action was accelerated. Danger was generally avoided by dilatation of the vessels. The pulse frequency might reach even as high as 250, and even after a ten hours' rest the pulse might still be accelerated—a sign of commencing cardiac insufficiency. The advantages of cycling with moderate exertion were obvious, and need not be dwelt on.

Overdriving was to be avoided. The dangers of a mechanical nature were—1. Injuries, which, however, were less with safeties than with the high machines. 2. Inflammation of the knee-joint might be set up by over-exertion, especially in the case of children. 3. Lesions of the general apparatus might be caused, especially inflammation of the prostate and the *para-urethra-posterior*. In women mechanical irritation of the ovaries might be caused by pressure of the *ileo-psoas* muscle, wherefore loose clothing should be worn and no corset.

A deforming influence of excessive cycling was not impossible; in the case of the very young, Pott's kyphosis had resulted. The general results of excessive exercise were emaciation, increased tendency to infective diseases and colds, especially irritation of the larynx and trachea. A good preventive of these colds was, in the case of professionals, a cold douche of 12.5° C., immediately after riding.

It is certain that injurious effects may be produced on the heart from cycling. Sudden deaths during or immediately after a journey are not rarities. This is not to be wondered at when we call to mind that for short distances at the rate of 61 kilometres per hour has been reached. At such a rate of speed overtiring of the heart is unavoidable.

OPIUM IN STENOSSES OF THE LARYNX IN CHILDREN.

Dr. C. Stern of the Marian Hospital, Düsseldorf, has a paper on the subject in the *Ther. Monatsch. V.* He commences with the remark that it is an old experience that children suffering from diphtheria or croupous stenosis of the larynx breathe with much greater difficulty when they are excited than when they are asleep, and that the breathing of children who have had tracheotomy performed is rendered easier by opium. On these grounds the author has given opium to children for whom tracheotomy was intended, and has found that the respiration had become calmer, and that the cyanosis had diminished. The action, according to the writer, is readily explained, as more air will pass through the narrowed passage when the inspiration is slow than when it is rendered difficult by an intense feeling of impeded respiration. By this calm breathing also the carbonic acid intoxication is relieved. He gives the history of three cases that demonstrate in his opinion the excellent effect of opium treatment. One patient, a child of 15 months, was sent into hospital for tracheotomy. There were excessive cyanosis, loud stridor, resonant cough, and retraction of the zypoid cartilage; 3 minims of tr. opii were given in sweetened water at 3 o'clock. At 5 the child had slept peacefully, breathed easily with

distinct stridor, the cough was less, the cyanosis distinctly less; 2 more drops of the tr. opii were given. The night was passed quietly. The following day 2 to 3 drops were given 3 times, and also on the two following days. On the third day the retraction of the zyphoid had disappeared, and on the eighth day the patient was discharged. The author thinks that opium ought always to have a trial before recourse is had to tracheotomy.

DEATH OF MR. JULIUS SKAMPER.

I regret to have to notice the death of Dr. Julius Skamper, from its commencement one of the most indefatigable collaborators of the *Deutsche Medicinal Zeitung*. A very familiar name will no longer meet the eyes of the readers of this extensively circulated journal. Those who have been accustomed to seeing it for so many years will sympathise with those more nearly associated with him in the loss they have sustained.

Austria.

[FROM OUR OWN CORRESPONDENT.]

Vienna, Jan. 10th, 1896.

LABYRINTH EXPERIMENTS.

KREIDL showed, at the "Gesellschaft," two cats on which he had operated experimentally. One of them had been operated on nine months ago, the other four months. Both exhibited Goltz's phenomena, usually met with when the function of the labyrinth is interfered with. It is now twenty years ago since Breuer drew the attention of this Society to the same subject, which does not appear to have advanced in knowledge since that time, as the same opinion is still retained concerning the semi-circular canals and the otolithic apparatus of the ear. The destruction of the portio mollis and the labyrinth in the mammalia has rarely been performed. The principal experiments on record are those on the dog by Schiff, and more recently by Ewald. Hitherto no experiments have been made on cats.

Kreidl at this point described his own method of operation, which differs somewhat from the preceding experimenters. The latter have always performed their operations by removing a part of the cranium or dividing the auditory nerve with a knife.

He performed the present operations by carefully removing all the coverings of the foramen rotundum, through which he reached the cochlea, by means of a finely constructed Paquelin, whose point was no larger than the opening of the canal for the auditory nerve in the cochlea. The wound closed up perfectly without any bad effects. During the operation, it was observed that the animal was quiet till the auditory nerve was reached, when it struggled and screamed piteously; at the same time nystagmic movements of a horizontal character were observed in both eyes. This phenomenon lasted from 24 to 48 hours after the operation, and could be repeated with any slight irritant fluid, such as carbolic lotion, in the wound. This phenomenon of the binocular auditory nerve nystagmus caused by injury to the auditory nerve is in perfect harmony with the results of Breuer and Mach's experiments. An important consideration in these experiments is the speedy return of the equilibrium, a result which might be expected in a highly-developed animal like the cat. In the case of the animal operated on four weeks ago the head was observed to incline towards the operated side. When placed on the table and food within sight of

it on the floor she would not venture to leap down, having no confidence in herself. In the other cat, nine months operated on, the labyrinth having been perfectly destroyed, there were still signs of disorganisation. She walked with a heavy gait, making pendulum movements with her head, and took her food awkwardly, from the peculiar movements of the head. When lifted in the air she clung tightly to the arm, owing probably to the disorganised sensation of the extremities.

SANITARY INSPECTION.

In the Austrian House of Commons the reorganising sanitary bill was warmly discussed. It is proposed to create sanitary inspection districts in Bohemia and Galicia, as well as a centralized sanitary inspectorate which is to be divided into four classes. It was finally resolved to retain a district surgeon in this office, and dispense with the present form of a sanitary clerk.

The Operating Theatres.

ST. THOMAS'S HOSPITAL.

PLASTIC OPERATIONS UPON EYELIDS BY THIERSCH GRAFTING.—Mr. ANDERSON operated on a girl, *æt.* 9, who had at the age of nine months suffered from a severe burn of the face, the cicatricial contraction from which had resulted in eversion of the upper and lower eyelids and other deformities. Operations had already been performed by Mr. Anderson for remedying the palpebral deformity by the transplantation of Thiersch grafts into the raw surface left by an incision freeing the lids, and allowing their replacement into the normal position; the effect of these operations had been almost entirely successful, but as slight eversion still remained a second operation was undertaken. A small incision was made at the free border of the upper lid immediately above the eyelashes; by dissection the lid was then drawn completely down, carrying with it the fibres of the orbicularis, leaving an elliptical raw surface; the lids were held in place by means of fine wire passed through the free border and fixed below to the cheek by means of American plaster; into the gap now exposed were transplanted Thiersch grafts of suitable size and shape taken from the thigh of the patient; the graft and adjacent portion of the integument were then covered with a thin layer of cotton-wool steeped in colloidion. After a similar operation on the upper lid of the opposite eye the retracted upper lip was freed by an incision through the cicatricial tissue at the root of the nose and the gap exposed on drawing the lip downwards was filled in with a Thiersch graft and dressed in the same manner.

The second case was that of a girl, *æt.* 19, who had suffered from a tubercular syphilis of congenital origin which had destroyed the whole of the nose, and had produced by its cicatrization a great eversion of the lower lids. The patient, when admitted, was suffering from extensive ulceration of the cheeks, upper lip, and of the interior of the nose; this was rapidly cured by large doses of iodide of potassium. The present operation was undertaken as a first step in the relief of the horrible disfigurement which the disease had produced. An incision was made immediately below the border of the everted lid; the lid was then drawn up with the orbicularis fibres and fixed in an upward direction by fine wires passed through the border and fastened to the forehead by means of strapping; the raw gap so exposed was filled in by Thiersch's graft as in

the last case, and dressed with collodion and cotton wool; the lower eyelid of the opposite eye was then treated in the same manner. Mr. Anderson remarked that the use of Thiersch's graft in ectropion promised good results. In the first case an ectropion of both lids in both eyes had been almost completely relieved by a single operation, and the repulsive aspect of the little patient had been removed. It was at first uncertain, he said, how far contraction would occur under a Thiersch graft in such a case, but the result proved that a very little of this took place. A second operation would probably, he thought, be necessary in most cases. The lip deformity in the first patient would very likely be relieved to an equal extent by the method of grafting, but in the second case it was proposed to remedy the retraction of the upper lip, while restoring the nose by a Tagliacotian operation.

GREAT NORTHERN HOSPITAL.

CASE OF INTUSSUSCEPTION.—GANGRENOUS INTESTINE WITHOUT URGENT SYMPTOMS.—MR. H. ALLINGHAM operated on a boy, *æt.* 3, who presented very few symptoms of abdominal trouble. He only vomited occasionally, the bowels had acted, the abdomen was not at all distended nor tender, pressure on it being well borne over its whole surface. The child had been carefully watched in the hospital for two days, but as the vague symptoms still continued it was thought advisable to open the abdomen to explore. It was found that there was an intussusception of the small intestine. Repeated attempts were made to reduce it but as these failed the intestine was opened, when it was discovered that the intussuscepted gut was in a semi-gangrenous condition, so that it was necessary to resect about eight inches of the bowel; the divided ends were united over Allingham's hobbin, this being easily and very quickly accomplished; a few Lambert's sutures were inserted. The intestine was thoroughly washed with carbolic solution and returned into the abdomen, and the external wound closed. Mr. Allingham remarked on the paucity of symptoms in this case; the only points that caused the performance of abdominal section were the aspect of the patient and the rapidity of the pulse. He also commented on the great facility with which the ends of the gut were brought together over the bobbin employed. On opening the piece of resected intestine it was found that the intussusception was due to the presence of a polypus somewhat of a sessile nature.

TREPANING FOR CEREBRAL TUMOUR.—The same surgeon operated on a case of Dr. Beavor's, a woman, *æt.* about 38, who was paralysed down the left side, and who complained of intense headache and double optic neuritis. As all these symptoms were gradually getting worse, Dr. Beavor thought an exploration was necessary. Mr. Allingham made a large semilunar flap on the right side of the head, exposing the area of the Rolando fissure. A large crown of bone was then removed with a large trephine, and, as the dura mater bulged into the wound and did not pulsate, Dr. Beavor advised that a larger portion of the bone should be taken away; this was done with Hey's saw and Horsley's bone forceps, so as to remove an area of bone four inches square. The dura mater was not opened at this the first operation, the skin flap being sutured back in position. Ten days later, the patient having satisfactorily recovered from the first part of the operation, the flap was turned down again and the dura mater incised all round the bone opening and turned down in a large flap. The brain was then carefully palpated to discover any increased resistance. None being

found the exposed brain was incised in various parts and the finger inserted well into the hemispheres, but no tumour being discovered the dura mater flap was replaced and the skin wound united. Mr. Allingham remarked that the interesting part of the operation from a surgical point of view was it having been done in two parts, thus avoiding excessive shock, which often followed the removal of a large mass of bone and the exploration of the brain or a removal of a tumour at the same sitting.

It is interesting to note that the tension was completely relieved, and the patient is in some points improved. The optic neuritis has gone and the headache has disappeared, but the paralysis still remains.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 15, 1896.

GLANDULAR THERAPEUTICS.

ONE of the most promising departures in modern therapeutics is certainly the utilisation of the internal secretions of certain glands to supplement their lack in the individual as a consequence of disease or removal of the corresponding organs. The field of what may be termed "glandular therapeutics" is being gradually extended, and the excellent results so far obtained warrant hopes of still more brilliant results in the near future. According to the theory held and enthusiastically promulgated by the late Dr. Brown-Séquard, all

glands, in addition to their obvious secretions, elaborate substances which pass into the blood, there to perform certain functions which, as well as their chemical composition, was still hugely obscure. We know such to be the case with the thyroid gland, we suspect as much in respect of the thymus, and it is extremely probable that other glands exert an influence over distant parts of the organism not as yet even suspected. The discovery that ablation of the testicles determines retrogression of the hypertrophied prostate opens up a field for speculation in the opposite direction, though experiments are still in progress with extracts of the prostate gland having the same object in view. The latest discovery of the kind is that removal of the ovaries will cure that ill-understood and fortunately rare disease, osteo-malacia. One of the first effects of this discovery will probably be to throw more light on the exact nature of this affection, for there is reason to believe that under this designation various pathogenic modifications of the osseous system are at present included. In this country we are only familiar with osteo-malacia as an affection of advanced life in spite of the fact that it is usually described as a disease occurring mainly, if not exclusively, during the child-bearing period of women's life. The cases reported abroad, moreover, usually comply with this definition, but the disparity is one which must be explained before we can get much further with the treatment of the disease. Osteo-malacia, or what is described as such in the aged, cannot very well derive its origin from changes involving the ovaries at their *point de depart*, and there are many other causes which may influence the nutrition of the skeleton without any reference to the sexual glands. The effect of removal of the ovaries in arresting osteo-malacia has led Professor Curatula, of Rome, to carry out some very elaborate investigations on the effects of castration on the metabolism of healthy animals. It is a matter of common observation that castrated animals usually put on fat, and one of the objects of the professor's researches was to ascertain whether this accumulation of adipose tissue is due merely to lessened vital activity or to the absence of some secretion formerly poured into the blood which facilitated the oxidation of fats. His results appear to point to the truth of the latter hypothesis. He found, for instance, that castration was followed by an immediate diminution in the amount of phosphorus eliminated in the urine, the proportion of nitrogen remaining the same. The subsequent subcutaneous injection of ovarian juice at once brought about an increase in the proportion of phosphates, the increase varying more or less according to the amount of the juice injected. Moreover, the elimination of carbonic anhydride by the lungs undergoes a similar diminution after castration, corresponding possibly to a diminished oxidation of fats, and this doubtless explains the accumulation of adipose substances in the organisms of castrated animals. In support of the view that the internal secretion of the sexual glands is concerned, indirectly at any rate, in the development of the osseous system, the author mentions that giants usually have atrophied

testicles, while, as a point of personal observation, the eunuch choristers of the Sistine Chapel all have massive skeletons. Cases of osteo-malacia, especially of the variety which alone can be supposed to be amenable to this treatment, are rare in this country—indeed almost unknown, but the principle involved, if substantiated, is one capable of extension, and is of great scientific interest.

THE OPERATIVE TREATMENT FOR IDIOCY.

DURING the past year the question of the operative treatment of idiocy came largely under notice. Since the results of this treatment, recorded by the French surgeons, were published some few years ago, a good deal of attention has been paid to the matter. Unfortunately, however, while the French cases seemed to hold out great prospects of much usefulness resulting from operative interference, the experience of other surgeons, both in this and other countries, was by no means encouraging in this regard. Part of this want of success has been attributed to the fact that the cases in question were not recognised as belonging to two classes—those in which the idiocy is due to arrest of development of the brain, as the result of which the skull remains small, and those where there has been premature union of the bones of the skull, in consequence of which the brain is unable to develop. In the latter cases the treatment advocated by the French surgeons would, in all probability, prove successful. But experience has taught that such cases are extremely rare, and that the bulk of those which come under the notice of the surgeon belong to the former category, for which operative treatment is clearly contra-indicated. Thus it may be said that a distinct advance has been made in respect to the treatment of these unfortunate cases, inasmuch as the recognition of the two classes of these patients will tend to prevent indiscriminate operating, a procedure which has in the past been attended with many untoward results. The latest contribution, however, to the subject is that of a comprehensive article by Dr. Charles Dana, of New York, published in the current number of the *American Journal of the Medical Sciences*. Upon the whole, this surgeon takes a more favourable view of the operative treatment of these cases. He claims that inasmuch as statistics now prove that the mortality from craniectomy has been reduced from forty to five per cent. it would be unjust to our art and inhumane to a large class of most unfortunate sufferers were surgeons to cease attempting operative interference. But the views which he holds with respect to the *rationale* of the operation are somewhat novel. His opinion is that it has a profound disciplinary effect upon the idiot, and that it is mainly through this that an improvement in these cases takes place. "The operation," he says, "is allied in its effect to a severe piece of castigation. In the very low type of criminals it is a well recognised fact by philanthropists that discipline and systematic work can only be obtained by actual corporal punishment in many instances, for nothing else seems actually to appeal to them. In the very lowest

grades of intelligence, such as we find in idiots and imbeciles, it is probable that only these very powerful inhibitory influences, such as accompany the performance of a capital operation, can affect materially the intellect of the child. It is through some such explanation as this that I would explain the fact that a second operation on these children is attended by further good results, and that sometimes the second operation is absolutely necessary before any result is obtained at all." Of course it is not impossible that some effect of the kind claimed by the author is produced by operative interference in these cases, but we are not prepared to accept his explanation in its entirety. We should be much more inclined to attribute most of the good which results from the improvement in the circulation and nutrition of the brain, arising from the release of some of the compression to which it has been subject. It may here be remarked that two specially important points are insisted upon by the author, namely, the age of the idiots and the types of cases in respect to which operative interference is indicated. So far as the former is concerned, experience has shown that the simple forms of idiocy with microcephalus are certainly not benefited unless operative interference is undertaken early in life, that is to say, under the age of four years, while with regard to the latter the chief indication for the operation is a moderate amount of microcephalus. When, however, distinct microcephalus is present the operation is not likely to be of any service, inasmuch as in these cases there is very great lack of brain development. The perusal, we may add, of the author's practical contribution to this subject, despite its somewhat sanguine tone, certainly tends to confirm the impression that in certain selected cases craniectomy may be attended with benefit in idiocy, but that in the majority of cases of the kind operative interference is contra-indicated.

THE FUTURE OF MEDICINE.

MODERN scientific medicine strikes its predominant keynote in the word "progressiveness." Its later history has been one long record of triumphs won by continuous and undaunted intellectual labour. The logical groundwork which the early Fathers lacked, in spite of all their subtle reasonings, was first formally supplied by Bacon, who undoubtedly laid the foundations of the marvellous superstructure of knowledge that is now being brought within the reach of every board-school pupil. The experimental testing of phenomena, insisted upon by our illustrious countryman has been steadily conducted ever since by workers in every part of the civilised world, and so great has been the result that in many instances the romance of one generation has become the realized and prosaic fact of the next. Increased accuracy of observation and of means of measurement has led to the accumulation of an enormous mass of ascertained phenomena, from which, every now and then, some master-mind has been able to deduct a great general law. Many examples will doubtless occur to readers, such as Newton's dis-

covery of the law of gravitation, Darwin's famous generalisation of the evolution of species, and Lister's great practical deduction of antiseptic surgery. The art of medicine, which depends on the support of many subsidiary sciences, has advanced step by step with the onward march of its faithful henchmen. Indeed, it may be broadly stated that there is hardly any discovery in the field of science that may not sooner or later be pressed into the service of this most comprehensive art of healing. What the future of scientific medicine may be it is far from easy to conjecture. Within the past twenty years many changes have become part and parcel of everyday practice. The introduction of antiseptics has revolutionised surgery, and has enabled the surgeon to invade many regions of the human body, hitherto sacred to the physician. Bacteriology, again, in itself an exact demonstrator of initial facts, has opened up an enormous field in the prevention of disease. Indeed, there seems to be no end to the fresh weapons of precision that are constantly being placed in the hands of members of the medical profession. One of the most marvellous of the whole series is that of organic therapeutics, as yet ill-understood and tentative, but full of promise of a brilliant future. Until more is known of this as yet evasive branch of special knowledge it will be well for all who are interested in the welfare and reputation of scientific medicine to suspend their judgment for the time being. To jump at conclusions is one of the most deeply-rooted of human tendencies, but such a course, however natural, is simply fatal to scientific life and development. So far as it is possible to draw a general conclusion from the near perspective of current events, one might be tempted to suggest that the trend of professional affairs lies mainly in the path of prevention. In other words, each fresh advance in the various departments of medicine, whether in methods of treatment, in improved habits and environment, will tend to lessen the amount of mortality and sickness incident to mankind. The dream of the public health enthusiast is to improve matters so that the majority of men shall live to three score and ten, while the death-rate shall be brought down to the irreducible minimum of five or seven per thousand of population. Nor does such a forecast seem altogether fantastic and extravagant when we consider the enormous saving of life that has already been effected since the introduction of systematic and scientific protection of the public health. On the whole, the future of medicine appears to promise a field of conquest which will end only when there are no more worlds to conquer, and the human race shall have worked out its own physical and preventive salvation.

DR. J. H. McAULEY, of Drumcondra, has been appointed medical officer of the Summerhill dispensary district of the North Dublin Union.

A JACKET made of aluminium has now been highly recommended as a spinal support in the treatment of lateral curvature.

Notes on Current Topics.

Public Libraries and the Dissemination of Disease.

PUBLIC libraries by means of the circulation of their books have repeatedly been accused of disseminating infectious disease. But, as a matter of fact, readily as such infection could be conveyed, no authentic cases have ever been recorded by which the accusation could be substantiated. Still the fact that this is the case does not by any means exonerate the library authorities from the responsibility of protecting the public. As bearing upon this point it is worthy of note that a librarian of a library in London, in a communication to a recent issue of the *Westminster Gazette*, shows that precautions of a definite nature are adopted in the public libraries, both of London and the provinces. In the first place there is sent to the library each day a list of all the dwellings in the parish where cases of infectious disease exist, and this list owing to the operation of the Infectious Diseases Act, is always complete. No books, under any circumstances, are issued to readers in the infected houses, and it is possible to ascertain those cases in which books have been borrowed before the disease was notified. Again immediate notice is sent to the respective borrowers to the effect that the books must not be returned to the library, but that they are to be retained and delivered to the sanitary authorities, who undertake to collect the volumes without delay and afterwards to thoroughly disinfect them. If any book should happen to be issued to a reader in a house where a case of small-pox has occurred the volume is at once burnt. The whole transaction in regard to collecting the books from an infected house occupies but a few hours, and thus in the event of a scarlet fever case, there is no danger of a volume being left until the period of desquamation begins. The enforcement of such an admirable system as this should undoubtedly be carried out at all public libraries throughout the country. As a matter of warning, it may further be added that borrowers who return to the library books which have been exposed to infection without properly disinfecting them are liable, under the Public Health Act (1875), to a penalty not exceeding £5.

Judgment in the Salicylic Adulteration Case.

MR. DE RUTZEN, the presiding magistrate at the Westminster Police Court, after taking some weeks for consideration, has delivered an elaborate and important judgment affecting the sale of British wines. It will be remembered (*MEDICAL PRESS AND CIRCULAR*, NOV. 13th, 1895) that the case arose out of a prosecution by the Vestry of St. George, Hanover Square, against Messrs. Walton, Hassell, and Port, under the 6th Section of the Food and Drugs Act, for selling orange wine containing salicylic acid. The public analyst gave evidence that he had examined a sample of the wine, and found that it contained '038 per cent. of salicylic acid, equivalent to 26·6 grains per gallon, a statement which was not disputed. He stated that even in this small proportion it was injurious to health, but admitted in

cross-examination by Mr. Rose Innes that he was not a qualified medical man, and that he had never had an opportunity of prescribing it for patients. Prof. W. H. Corfield, the well-known sanitary authority, said that the chief use of salicylic acid was as an application for corns, and proceeded to argue that a drug which would remove these excrescences must, of necessity, act injuriously on the mucous membrane of the stomach. He was apparently unaware of its use as a remedy for rheumatism and other joint affections, and maintained that it was not given internally. For the defence Dr. Murrell, of the Westminster Hospital, gave evidence as to its pharmacological action, and Mr. Thomas Bond, F.R.C.S., stated that he had not only taken it himself, but had prescribed it in hundreds of cases, both in hospital and in private practice. During a recent epidemic of sore-throat among the police of the district he had used it largely and with undoubted success. An element of humour was introduced into the proceedings by the statement of the analyst that he had never heard of Mr. Bond, and that he was under the impression that Dr. Murrell kept a chemist's shop in the neighbourhood! Mr. De Rutzen, in giving judgment, said that he had no hesitation in dismissing the summons on the ground that the case came within the Act, that the drug in the quantity used was not injurious to health, and had not been added to the wine to increase its bulk or conceal inferiority of quality, but solely as a preservative and for the sake of its antiseptic properties. Mr. A. Gill, the counsel for the prosecution, said that the Vestry could not appeal, as his Worship had decided on the question of the facts. The case is of interest not only to manufacturers, but to medical men, and as salicylic acid in varying quantities is largely employed for the preservation not only of wines, temperance drinks, and German beers, but of cream, milk, extract of malt, and especially jam, it is not improbable that further prosecutions will be instituted in different parts of the country, and that the whole question will be fought out on somewhat different grounds.

The Direct Representatives for Ireland in the General Medical Council.

THE competition for the position vacated by the late Dr. Kidd, continues to be acute and interesting, although the necessity for the prior election of a new Registrar of the Branch Council will cause the polling to be deferred to the end of February. The only light which has been thrown upon the position of the various candidates since we last wrote has been shed by the issue of the list of the Committee of Professor Cuming, of Belfast, which is, in itself, an instructive document. The Committee which represents Dr. Cuming says to the reader: "You will learn from this list how very extensive and strong the feeling is in favour of the principle of returning a provincial practitioner. We think that a favourable opportunity now exists for wresting the representation from a metropolitan candidate." Let us see how far the Dr. Cuming list indicates this "extensive and strong feeling." We rather think that it proclaims Dr. Cuming to be the most

ocal and the least provincial of all the candidates in the field. It contains altogether 343 names. Of these, Belfast City returns 142, mostly Professors and teachers in the Queen's College, and in the Local Hospitals, and outside the City walls. The counties of Antrim and Down, which may be called the suburbs of Belfast, return 119 other names. The adjoining counties of Derry, Tyrone, Monaghan, Armagh, and Donegal return 47 names, and Dublin sends eleven. Dr. Cuming's following throughout the whole of Ireland, outside Belfast, and the half-dozen northern counties, numbers exactly 24 persons, out of a possible total of about 1,800. We recommend the study of these figures to Dr. Cuming's Committee and advise them, in their next address, to offer him to the working medical practitioners of Ireland as a much esteemed teacher and consultant, and as the incarnation of the educational interests of the Belfast Queen's College. In these capacities no one can cavil at his pretensions.

Superstition and Insanity.

PERSONS who unwisely allow themselves to become very superstitious are commonly disposed at times to be highly emotional, a condition of things which may result in the over-balancing of their mental equilibrium. The following case, related by Dr. James Kiernan, of Chicago, which may be described as a "True Ghost Story," is of interest in this connection. A young man brought up on a farm was much given to the perusal of sensational literature. He was very superstitious and frequently expressed a fear of ghosts. The boys of the neighbourhood, becoming acquainted with his weakness, devised a plan to frighten him with a pretended spectre at midnight. He always slept with a large revolver in easy reach. During the day the ball cartridges were replaced by blank cartridges and the weapon restored to its usual place. At midnight the victim of the practical joke was awakened by a seeming spectre which stealthily entered the room and stood with outstretched arms, muttering unintelligibly. The victim hurriedly grasped the revolver and sat upright in bed, dumb with fear. The ghost advanced a step; the muttering continued. When the young man, wrought up to almost a frenzy, drew the weapon and stammered, "If you are a man, I shall kill you; if you are a ghost, this won't hurt you," and fired. There was a quick motion of the shrouded arm and the bullet was thrown back, striking the head of the bed. A second time he took deliberate aim at the figure and fired. Again a motion as if catching the bullet, and it also was thrown back upon the bed. He fired a third, a fourth, and a fifth shot, only to have the bullets hurled back, with noiseless motion from the ghostly figure. Then for a brief moment he sat as if transfixed, gazing with mute bewilderment, when with a wild shriek of terror he fired the last blank cartridge and hurled the pistol at the ghost. When the pretended ghost revealed himself, the victim was found in a state of unconsciousness, which gave way to an incoherent frenzy accompanied by marked initial hallucinations of sight and hearing. He recovered after three months' treatment in an asylum. One of the planners

of this senseless practical joke became insane through remorse, and exhibited similar symptoms; but, unlike the ending which a novelist would probably have accorded him, he also made a good recovery.

The Calcutta Medical School.

RAI LAL MADHUB MOOKERJEE, BAHADUR, is the chairman of the Calcutta Medical School Committee, and he had the honour recently of giving an address before Sir Charles Elliot, of the Bengal Presidency, who had undertaken to preside at the annual distribution of prizes at the school. We learn from the first-named gentleman that the "eight long years that have passed since we first started have been also chequered (*sic*) with many happy and encouraging incidents. During these years the Calcutta Medical School has been fortunate to secure the confidence of parents and guardians throughout Bengal, as the roll of students amply testifies. We have now on our rolls more than five hundred students from the different districts of Bengal, and we have sent forth from our institution medical practitioners who are now doing their angelic (*sic*) work in ministering to the sick and infirm and bringing joy and happiness to the homes of our rural population." It must be confessed that this is a very encouraging report, and shows the great progress that has been made by the Calcutta Medical School, "chequered" though that progress may have been "by many happy incidents." We can quite believe that a still further prosperous career is in store for this school, and everyone must hope that for many generations to come it will continue to pass out into this suffering world a numerous body of its alumni, fully capable of maintaining the "angelic" standard of work which appears to have been already attained by its students.

Experimental Diabetes.

THE series of experiments carried out by Professor Biedl, of which our Austrian correspondent gave a synopsis last week, in reference to the experimental production of diabetes, show that much work remains to be done before we shall understand, even approximately, the mechanism of the production of glycosuria and diabetes. One point, however, is made clear, *viz.*, the untrustworthiness, in this particular branch of investigation, of experiments made on dogs. Counter-observations on the human subject proved that the processes of disintegration and elimination of sugar in dogs cannot safely be trusted to furnish data capable of application to man. The general result of Dr. Biedl's experiments is to show either that sugar does not, as is usually supposed, act as an irritant to the glandular structure of the kidneys, or that, in the healthy individual, it is so promptly changed as not to exercise these effects. The injection of sugar in several cases determined a more or less pronounced rise of temperature of the nature of a rigor, similar to that observed during the transfusion of blood. He never succeeded in demonstrating the presence in the urine of sugar injected into the veins, and even when, in the hands of other observers, this has been accomplished, all

trace thereof had disappeared at the expiration of twenty-four hours. There remains for study certain peculiarities in the urine of the subjects of these experiments, the nature and significance of which we still observe.

Pompeian Surgery and Surgical Instruments.

NEARLY two thousand years have elapsed since the Pompeian surgeons practised their art in their ill-fated town, and yet many objects of interest to the surgeon have since then been brought to light during the vast excavations undertaken for the purpose of exposing the ruins of Pompeii. In an interesting paper on this subject in the last number of the *Philadelphia Medical News* Dr. N. Senn gives a description of a recent visit that he made to the ruins of Pompeii and the Naples Museum, and enters fully into the account of what he saw in the nature of Pompeian surgical instruments. The instruments were found in a house which has been called the "Surgeon's House." They are made of bronze, and some of them show a high degree of workmanship. Some of them indicate also the destructive effect of heat and oxidation, while others are in a state of excellent preservation. Careful search was made among the instruments for traces of needles or any appliance which would indicate that at that time wounds were sutured. But nothing of the kind was found. The collection, moreover, did not contain any saws, trephines, chisels, or instruments for operations upon bones. Again, with the exception of the specula and catheters, it is curious to note that the instruments were of a diminutive size in comparison with those of less remote and more modern times. Judging from his instruments, the Pompeian surgeon plainly confined his "cutting" operations to bleeding, cupping, extraction of foreign bodies, and the opening of abscesses. Dr. Senn concludes his paper by pointing out that the surgeon of Pompeii must have been a man of means and good social position; the position of his house in the most aristocratic part of the city, and its capaciousness, both testify to this fact. A liberal income, therefore, probably rewarded his labours and placed him in a position to enjoy the luxuries of life, which seem to have been the main object in life of the mass of the Pompeian people before the destruction of their city.

The Mystery of Hearing.

PROFESSOR MCKENDRICK, in one of his juvenile lectures last week at the Royal Institution, enunciated some new views upon the interesting subject of "Hearing." In his description of the internal ear the opinion was expressed that the latter was a complex labyrinth of winding staircases containing fluid. In the innermost recesses were the essential organs of hearing, a wonderfully arranged mass of fibres and cells, from which fine hairs were suspended in the fluid; and his belief was that each of these hairs was in direct connection, by its nerve thread, with the brain. This point is of much interest because it shows how Nature gets over the difficulty of transmitting an air vibration

into a fluid. But the problem which Professor McKendrick put forward to solve before his audience was how this complex apparatus picked out and analysed the infinitude of shades of tone that are borne upon it. He suggested that each of the delicate hairs or fibres was attuned to respond to a certain shade of tone, and picked up the note to which it was attuned precisely as one tuning fork picked up the sound of another if they both happened to be of the same pitch. The number of different shades of sound in Nature is probably enormous, but as Professor McKendrick pointed out the number of these sensitive hairs is enormous too. In proof of this it may be asserted that an acute musician will detect so slight a difference in tone between two notes as the one-sixth of a semitone. This means that in the eleven octaves that the human ear compasses there are some 8,000 or 9,000 consciously different tones at least. There are about two hair cells to each one-sixty-fourth of a semitone.

Infected Heirlooms.

To become the possessor of old family relics, to step into the shoes of one's ancestors, to inherit the family mansion with all its old associations, its antique furniture, its ancient tapestry, is usually regarded as an enviable lot. But this is a prying, enterprising, unromantic age, which is not apt to be deeply impressed with things as they seem. Sometimes in this connection cruel discoveries have been made by science, cruel in the sense of bursting like a bubble cherished traditions, romantic beliefs, and the rationality of time-honoured customs. Something in that sense has just transpired in regard to the almost sacred possession of certain heirlooms. Some cool-headed, calculating, severely matter-of-fact bacteriologist has actually had the audacity to examine into the bacteriology of some old, beautiful, and otherwise priceless tapestries in an old country mansion. What were the results of his investigations? Must the truth be revealed? What good, it may be asked, can come from concealing it? This bacteriologist found that the tapestries were teeming with micro-organic life, and that they were nothing less than hot-beds for the culture of tubercle bacilli. Will the mural adornments of the "tapestried chambers" throughout the country survive this terrible indictment. It may be that they will. But who after this will be able to look upon the "tapestried" presentments of, say, the lively "Adventures of Dionysius," the wonderful career of "Medea," or the patriotic manoeuvre of "Mettius Curtius," without some feeling of repulsion which such a revelation could not fail to create!

The Salvation Army Shelter Case.

MOST of our readers will probably remember that the action of the Vestry of St. George the Martyr, London, as regards the Blackfriars Salvation Army Shelter, resulted in a magistrate's order against future overcrowding. After an interval of six weeks the defendants have obtained a ruling from the Queen's Bench calling upon the magistrate concerned to show reason

why his order should not be quashed. The disputed order was to the effect that the defendants should abate the nuisance of overcrowding, which was dangerous and injurious to the health of the inmates. In asking for the rule counsel for the late defendants contended that those who made use of the shelter could not be called inmates, on the ground that a person who passed one night in a house was not an inmate in the sense in which the wording of the Act was used. The fault of the magistrate's order, according to applicant's contention, was that it did not state what was to be done to abate the nuisance, and an order could not be good unless it stated what they had done and the remedy were specified. From this application it seems evident that the Salvation authorities will leave no stone unturned in their strenuous efforts to upset an adverse legal decision. The unprejudiced onlooker would probably reflect that the best thing for the Army would be to bring their night shelters into line with the views of local sanitary authorities.

Houses Built on Ash Heaps.

THE Medical Officer of Health for Hackney has once more called attention to a besetting sin of jerry-built houses. In a lately issued report he pointed out that many of the houses in his district were built upon a layer of house refuse, which in turn rested upon a bed of clay. Such a condition of affairs naturally leads to the drawing into the house of various gases of decomposition and of other components of ground air. This danger has been discussed in our own columns for many years past. That it is a common and fruitful source of disease can hardly be doubted. In many parts of the suburbs of London it is a constant practice of the enterprising builder to fill up with ash-pit refuse any pit that has been quarried for stone, sand, or other material. He then proceeds to run up a more or less showy villa on this green mass of miscellaneous animal, vegetable, and mineral stuff. As a rule, the basement is not provided with an impermeable concrete flooring, so that the house settles, the drains are dislocated, and the inside of the house becomes permeated with poisonous ground air. The remedy is simple. No new house should be occupied until it has been duly inspected and certified as properly constructed by a competent sanitary authority. At present, the remedy which the tenant of an unhealthy dwelling has against his landlord is slow, tedious, and uncertain. The advent of some searching and practical domestic legislation would speedily put an end to the ghoulish race of jerry-builders.

Serious Charge against a London Sanitary Inspector.

DURING the past few weeks considerable sensation has been caused in a South London district in consequence of certain charges brought in the first place against an assistant sanitary inspector. This official, so it appears from a published letter, wrote to a house agent asking (1) for full particulars regarding the disposal of certain houses in the parish, and (2) what commission the agent was prepared to pay. His com-

munication was laid before the health committee of the Vestry, and, as the result, that body shortly afterwards accepted the sub-inspector's resignation. Subsequently, however, the ex-official wrote to the *South London Press* a letter in which he asserted that he had written letters like the one complained of to other house owners in Bermondsey. This grave charge was brought before the Vestry for discussion, and the inspector was exonerated. At the same time it was freely asserted that the officials were allowed to act without sufficient control, and that the sanitary committee itself was not free from blame. It seems clear to us that charges of this extremely serious nature can be properly sifted only by an independent inquiry. It is equally clear to us that the Local Government Board should undertake the investigation forthwith. The question of the purity and honesty of the servants of the medical officers of health is one of vital importance to the future of public health in the metropolis. The fact that the chief official implicated is the chairman of the Sanitary Inspectors' Association makes it all the more imperative that an independent Government inquiry should be made upon every one of the issues raised.

The Composition of Microbes.

SOME investigations have been recently undertaken with a view of ascertaining the proximate and ultimate composition of micro-organisms. Tubercle bacilli were found to contain cellulose, together with palmitic and arachidic acids; on the other hand, the bacillus of glands appeared to contain no cellulose, while the acids present were oleic and palmitic. The microbes of these experiments were cultivated on the same media, and, with the exception of the nitrogen, there seemed to be but little variation in their composition when the medium was varied. The results of elementary analyses of three forms (the two above mentioned and the bacillus of swine fever) showed marked differences in the proportions of nitrogen, carbon, hydrogen, and ash present.

Sir Thomas Moffett.

THE honour of knighthood conferred, last week, upon Dr. Moffett, President of the Queen's College, Galway, has been, as will be universally admitted, most deservedly given. There is, we believe, no man in Her Majesty's Civil Service in Ireland to whose advancement, if it may be called so, less exception could be taken by any person or party than Dr. Moffett. He has shown himself to be not only the possessor of exceptional attainments, but a most able administrator and a gentleman in every sense of the word. We congratulate the Lord Lieutenant on having discerned his merit and rewarded it, as far as he has been able.

THE St. Helens' Corporation decided some time ago to conduct a series of bacteriological investigations into the origin and spread of typhoid fever, with special reference to the St. Helens' district, and at a meeting of the Health Committee last week a bacteriological assistant was appointed, at the salary of £12 per month.

The Personal Estates left by Medical Men in 1895.

THE following is the list of the well-known physicians and surgeons who died last year, and the value of their personal estates:—Sir William Scovell Savory, Bart., F.R.S., sixty-eight, Surgeon-Extraordinary to the Queen, and ex-President of the Royal College of Surgeons, £93,190; Sir George Hornidge Porter, Bart., seventy-three, Regius Professor of Surgery in Dublin University, £57,326; Sir John Tomes, F.R.S., F.R.C.S., L.D.S., eighty, £51,897; Sir George Buchanan, F.R.S., sixty-four, medical officer to the Local Government Board, £7,739; Sir Thomas Crawford, K.C.B., seventy-one, Hon. Surgeon to the Queen, Director-General of the Army Medical Department, £7,036; Dr. John Syer Bristowe, F.R.S., sixty-eight, consulting physician to St. Thomas's Hospital, £15,734; Dr. Daniel Hack Tuke, sixty-seven, Hanwell, £29,460; Surgeon-General Sir Thomas Longmore, seventy-nine, professor, Netley, £19,659; Surgeon-General (retired) John Irvine, sixty-seven, who was with Havelock's column at the Siege of Lucknow in 1857, £4,285. It has been estimated that the average of the personal estates of sixty-seven physicians and surgeons whose wills were noticed during six or seven years was £50,614, or less than half of that of forty-four solicitors. Of course, the solicitor has the advantage over the medical man in having opportunities of investing his money safely at good rates of interest. Again, the expenses of carrying on his professional calling are much higher, *pro rata*, in the case of the medical man than in that of the solicitor. For these and other reasons, wealthy medical men are much less common than wealthy solicitors.

The Conviction of John Ferdinand.

THE quack, John Ferdinand, "M.D., U.S.A.," who appealed against the conviction by Mr. Sheil for "unlawfully and falsely representing himself to be, and using the name and title of, a doctor of medicine," and by whom he was ordered to pay a fine of £20 and £10 costs, has come to grief for the second time. The appeal was heard last week at the Clerkenwell Sessions before Sir Peter Edlin and a bench of magistrates. After a short statement of the case had been made by Mr. Mackenzie for the Medical Defence Union, and the appellant had been heard, the magistrates at once confirmed the conviction. The idle boast of John Ferdinand, "M.D., U.S.A.," that he would prove his claim to be a medical man, has thus been severely disposed of.

The Post of Director-General of the Army Medical Department.

THE post of Director-General of the Army Medical Department will shortly fall vacant, Surgeon-Major-General Sir W. A. Mackinnon retiring, after being at the head of the department since 1889. It is stated that he will be succeeded as Director-General by Surgeon-Major-General Jameson, M.D., who is now serving at head-quarters as professional assistant to the Director-General, a post he has occupied since April,

1893, when he succeeded Surgeon-Major-General Reade. Surgeon-Major-General Jameson joined the Army Medical Staff in 1857, and served as principal medical officer in Egypt before joining the head-quarter staff. He served with the English ambulance in the Franco-German War of 1870.

The Royal College of Surgeons, England.

AT the quarterly meeting of the Council of the Royal College of Surgeons, England, held last week, some important business was transacted. One of the principal matters dealt with was that relating to the resolution passed at the meeting of Fellows in regard to the representation of the Members on the Council. The Council decided to refer the resolution to their Deputation Committee to consider and report thereon; probably, therefore, some time will have to elapse before any final decision is arrived at upon this important question. The Deputation Committee consists of the President (Mr. Heath), the two Vice-Presidents, Mr. Reginald Harrison and Mr. Pick, also Mr. Rivington, Mr. Morris, Mr. Bryant, Mr. Howse, and Mr. Tweedy. Another resolution passed at the Fellows' meeting, "That in the opinion of the Fellows of this College women should be admitted to the Diploma of the College," was briefly discussed, but no definite action was taken in regard thereto; all that was done was to instruct the Secretary to enter it upon the Minutes.

The Small-Pox in Dublin.

THE epidemic of small-pox has nearly, but not altogether, disappeared from Dublin. In the week before last no case was admitted into hospital, but last week one case was admitted. Eight cases still remain under treatment, being three under the number for the preceding week.

Leprosy in Norway.

THE latest accounts seem to show that leprosy is decreasing in Norway. In 1856 there were about 3,000 lepers in that country; in the latter end of 1892 there were only 900 cases. The statistics of Dr. Kaurius recently published on the subject, show that a strict segregation of lepers is an important element in the suppression of the disease.

THE *Sun* newspaper last week informed its readers that a man unknown died in the Park, Croydon, from serious apoplexy from over-exertion.

PROFESSOR RAY LANKESTER, of Oxford, has been elected a corresponding member of the Russian Academy of Sciences.

THE Cheyne Hospital for Children, Cheyne Walk, Chelsea, has received a present of game from the Princess of Wales, who is the President of the Hospital. Captain Frederick Saunders has forwarded a cheque for £300 to the Committee as a grant from the estate of the late Miss Caroline Saunders.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

NOTIFICATION DIFFICULTIES AT DUMFRIES.—Still another instance of friction in the working of the Notification Act comes from Dumfries. In that town measles is not one of the notifiable diseases, and the Medical Officer called on the Sanitary Inspector to remove a servant of his who was suffering from this disease to the fever hospital. The inspector refused to order her removal, whereupon the doctor had her taken on his own order. The Dumfries Town Council, on a report of the Committee, have repudiated the liability for the cost of maintenance of the patient on the ground above stated, that measles is not notifiable in the town, and have resolved that no case be removed to the fever hospital at their charge without an order signed both by the sanitary inspector and the medical officer of health, the Committee also to have a word to say in the business, if the patient is to be kept at the expense of the town. In time the poor patients of Dumfries will have to conduct a sort of personal canvass of the members of the Council before they will be able to gain admittance into the town's hospital. The Committee characterised the action of the doctor as high-handed, but surely the medical officer of health should be able to tell whether he can isolate a case of measles in his own house or not. A doctor's house should always be kept free of infection more than other houses, especially the dwelling of the local officer of health. Fancy what a noise these same busybodies would have made if they had discovered later that measles was being spread from the house of their own medical officer!

EDINBURGH UNIVERSITY ANNUAL REPORT.—Of the total number of students at the University of Edinburgh in 1895 (2,836), 1,475, or practically the half, were students of medicine; of these, 43 per cent. belonged to Scotland, 31 per cent. to England and Wales, 5 per cent. to Ireland, and fully 13 per cent. to the British Colonies. Thirty-nine women students attended extra-mural lectures with a view to graduating in the University. The over-crowded ranks of the profession were further re-inforced by the addition of 221 M.B.'s, C.M.'s, while 71 physicians took their M.D. degree. The General Council of the University now numbers 7,891 members. The annual value of the university scholarships, bursaries, and prizes in the Faculty of Medicine amounts to £2,800.

THE EDINBURGH ROYAL INFIRMARY.—The Edinburgh Royal Infirmary report is a most satisfactory one. The number of patients treated during 1894-95 exceeded all previous records, the total being 10,032, while the cost of maintenance is less by 17s. 5d., and the cost of medical necessities by £1 15s. 8d. per occupied bed, than was the case last year. The total cost per annum of each patient works out at £55 8s. 2d., or £3 2s. 2½d. below last year's figures. A net surplus of £2,627 remains from the year's accounts. Besides this large legacies are due in spring, when the whole of the existing debt on the building will be wiped out. We wonder how many hospital managers and secretaries will be tempted to break the tenth commandment when they read these details.

THE ROYAL MEDICAL SOCIETY, EDINBURGH.—Dr. T. S. Clouston delivered the inaugural address of this society on the 8th inst. Owing to his being indisposed the address had been postponed from last November. Dr. Clouston said that it was of immense value to get firm hold of principles of general application. Such an enormous multiplicity of facts were presented to the student that he was in danger of missing the great principles which explained those facts and brought them into relationship with each other. The principle which he wished to impress upon them was that the cortex of the brain, its higher and ultimate part, with the highest function of mind, must be taken into account in the diagnosis, prognosis, and treatment of almost all diseases and injuries. It was an important fact that a merry heart would always act as a medicine in every disease and be a help to every kind of treatment adopted, and that cheerful impressions on all the senses—light, colour, pleasant society, and confidence in their doctor—would by their tonic influence help the cure of every curable disease, and make every wound and injury heal the faster. Dr. Laycock was the first to point out the enormous influence of the brain and of diathesis on disease.

THE LEITH HOSPITAL CASE.—As was expected, the Court of Session have repelled the pleas of the Leith Dean of Guild Court on which they relied when they refused to allow the Corporation of Edinburgh to build a temporary hospital within their boundaries. The matter has, therefore, been again remitted to the Leith authorities to deal with, the Lord President of the Court of Session significantly remarking that he could not doubt that now the matters would be treated in a business-like spirit proper to a Dean of Guild Court. As the Leith authorities have to pay the costs of the appeal, and probably of the preceding petition, they must now be exceedingly sorry that an unreasoning jealousy of their larger neighbour led them into such a false and puerile position.

WOMEN'S MEDICAL SCHOOL, GLASGOW.—Woman doctors who are to be educated in Glasgow now have an Anatomical College building complete in itself devoted exclusively to their use in the study of anatomy and physiology in connection with Queen Margaret's College. Funds to the extent of £5,000 for the building have been handed to the University Court of Glasgow by the Bellahouston trustees.

MEDICAL SOCIETY OF LONDON.

The meeting on Monday evening last (January 13th) was devoted to the reading of and discussion upon a paper by Dr. Savage on "The Treatment and Classification of the Insanity of Pregnancy and the Puerperium." He suggested their classification into mental disorders occurring in pregnancy (1) in the earlier months, and (2) in the later months of pregnancy; the insanity of labour, (1) hysterical and transient, and (2) more lasting and permanent; ephemeral insanity [associated with the onset of milk; insanity during the first fortnight after labour; insanity coming between fourteen days and six weeks after labour; the insanity of lactation; and the insanity of weaning. He pointed out that there was no special well-defined form of insanity deserving the name of puerperal insanity. Only a small proportion of patients had suffered from hysteria, but some had had previous attacks of insanity, the liability being apparently in direct proportion to the frequency of the previous attacks. He raised the question as to how far one was justified in recommending or discountenancing marriage in the case of neurotic women. He mentioned that first pregnancies were most dangerous in respect of the supervention of insanity, especially when they took place after 30 years of age. He added that one variety of puerperal mania coming on soon after labour was believed to be due to sepsis. Early insanity was usually maniacal, while if later, it tended to take the melancholic type. About 3 per cent. of patients died from puerperal mania, but upwards of 20 per cent. remained more or less permanently weak-minded.

The President (Sir J. Crichton Browne) criticised the classification, which he said, if practical, was certainly not scientific. He related two cases of girls with marked hysteria respecting whom he had foretold trouble on child-bearing, but nothing of the kind had occurred.

Dr. Blandford pointed out that 80 per cent. of these cases recovered pretty soon, and the proportion would probably be higher if all outside cases were included. He did not believe that hysteria had much to do with its production.

Dr. G. Herman believed that puerperal mania was a distinct form of insanity deserving of a special designation. He declined to admit that marriage could ever be safely recommended for the cure of any nervous trouble. Of hypnotics for the relief of the initial sleeplessness he preferred full doses of alcohol.

Dr. Robert Jones, of the Claybury Asylum, said the asylum had only been open two years since, which time they had had 60 cases of insanity associated with pregnancy or parturition out of 2,400 female patients, the proportion of puerperal to the female insane being 1 to 48. There had been 30 confinements, in only two of which was albumen present in the urine, and in neither of these cases did convulsions take place. There were 7 cases of mania from lactation, and 1 case of melancholia, while of patients with insanity associated with pregnancy 6 were maniacal and 4 melancholic. The average age of the melancholics was over 30, while in mania the usual age was about 25. Of the 60 patients 32 appeared to have recovered, and 15 might

be said to be convalescent. It was rare to meet with elevation of temperature in these patients, and he pointed out that this fact was inconsistent with the view that sepsis was a common cause.

Dr. Andriezen, Dr. Leith Napier, and Dr. Bower also spoke, and Dr. Savage briefly replied.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

WHAT IS A NATURAL LABOUR?

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR.—The amount of comfort which certain members of our profession derive from the consideration of the term "natural labour" reminds me of an old Scotch lady who was often heard to say that her existence would be quite insupportable but for that blessed word "Mesopotamia."

Having occasion to speak on this subject at the meeting of the Lancashire and Cheshire Branch of the British Medical Association held at Liverpool, on January 8th, to consider the draft Midwifery Nurses' Bill of the Council, I thought it wise to submit the definition clause of that Bill, which contains the term in question, and also some others of very vague import, to Messrs. Boote and Edgar, solicitors, Booth Street, Manchester, who kindly furnished me with a valuable legal opinion.

The definition clause of the Bill reads thus :—

CLAUSE 2.—DEFINITIONS.—In this Act.

The term "midwifery nurse" means a woman who attends cases of natural labour, and afterwards tends the mother and child during the lying-in period, under such rules, regulations, and medical control or supervision, as may be from time to time laid down by the Midwifery Nurses Board.

The questions submitted and the legal answers to the same I append.

QUESTIONS—

What is the legal significance of the term "natural labour" and the words "medical supervision and control"? Do the latter words necessarily imply medical assistance?

Having regard to the meaning of these terms, what legal powers in restraint or regulation of practice, have the Midwifery Nurses' Board under this Bill?

LEGAL OPINION—

It is impossible to say what is the legal significance of the term "natural labour." If any question arose in a Court of Law as to its significance the Court would have to rely upon the evidence of experts, i.e., medical gentlemen. In all probability the words "natural labour" would be defined to mean a labour which originated other than artificially, i.e., by the means of accident, drugs, or instruments, or other than in the ordinary course of nature.

There is no special legal significance attached to the words "medical supervision and control." These words do not necessarily imply medical assistance, and it would be quite competent for the Midwifery Nurses' Board to dispense with the same.

How the ease or difficulty of a labour affects its perfect naturalness is hard to understand, and I hope, in connection with any proposed midwifery legislation, to hear no more of such a blockhead of a term as "natural labour."

It is also very desirable that the Midwives' Board should not have power to dispense with medical assistance, but that the obstetric functions of the midwife should be very clearly stated in the Act itself.

I am, Sir, yours, &c.,
WM. FRASER.

Salford, Jan. 11th, 1896.

MEDICAL TITLES AND THE MEDICAL DEFENCE UNION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your correspondent "H. S." will be, perhaps, surprised to learn that the conviction of Ferdinand,

"M.D., U.S.A.," was confirmed on appeal this day at the Clerkenwell Sessions, with costs; personally, neither the law officers of the Medical Defence Union nor I expected otherwise. If your correspondent will communicate his address I shall be very glad to forward to him copies of our Annual Report, which will show the number of convictions we have obtained in 1895; the earlier reports he can also obtain.

I am, Sir, yours, &c.,
A. G. BATEMAN,
Gen. Sec., M.D.U

London, January 11th, 1896.

DR. CARTER'S THERMO-INHALER FOR ETHER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your report of my remarks made upon the subject of Inhalers before the Society of Anæsthetists, and appearing in your impression of January 8th, at page 32 your reporter has misunderstood what I said. Speaking of the ether inhaler shown by Dr. Carter, and made by Mr. Krohne, I said "My experience of the apparatus is not all in its favour." The omission of the "not" makes me express approval of an apparatus which I consider has many grave defects. Before the words "When these apparatuses failed to prove satisfactory, he said it was due to a want of experience" an important omission has taken place. I was speaking of the apparatuses devised by Mr. Clover, and it was to these I referred, and not to Dr. Carter's. The failure to obtain sufficient anæsthesia with the "Thermo-Ether-Inhaler" is due, I contend, to inherent defects in its construction, and not necessarily to the manner in which it is manipulated.

I am, Sir, yours, &c.,
DUDLEY BUXTON.

82 Mortimer Street, W.

The Apothecaries' Hall, Ireland.

THE Apothecaries' Hall conferred its Licence (hon. 'caus.) last week upon Sir Charles Cameron, a distinction which is the more appreciable because of its rarity, for we believe that the honour was conferred on but, one, or at most, two previous occasions in the history of the "Hall."

The Compounding of Medicines in Workhouse Hospitals.

At the meeting of the Enniskillen Board of Guardians last week, the Right Hon. the Earl of Belmore presiding, Mr. William Wilson said that at a meeting of the committee appointed to fix the salary of the medical officer to the workhouse, it was stated by the Master that the nurse was in the habit of compounding the medicines. He said if this was the custom in the past it ought not to be continued in the future. He considered that in the advertisements they were about to issue for a medical officer to the workhouse it should be stated that the doctor would have to compound the medicines. After some further discussion the Master stated that the doctor simply wrote out the prescriptions, and the nurse compounded the medicines. Mr. Brown, J.P., said it was a very important question. The chairman said that it was, as if anything happened the guardians might be held responsible. It was decided to state in the advertisements that the doctor appointed would be held responsible for the compounding of the medicines.

Professional Ethics and the British Gynæcological Society.

At the last meeting of this Society, held on the 7th inst., the following resolutions were submitted to a large meeting :—

1. That it is undesirable that any member of the medical profession practising homœopathy should be proposed as a Fellow of the Society. This was carried with only four dissentients.
2. That it is contrary to the ethics of the British Gynæcological Society that any of its Fellows should advertise their publications, or otherwise bring themselves before the notice of the public by advertising in any way through the medium of the lay papers. This was carried unanimously.

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

THE LATE DR. KISBY, OF CARRICKMACROSS—A DESERVING APPEAL.

SIR.—Doubtless you have already heard of the sad death of Dr. W. J. Kisby, Medical Officer, Rathfriland Dispensary District, whilst at the post of duty. As he has left behind him a widow and large family of young children almost wholly unprovided for, a committee, as mentioned below, has been formed for the purpose of assisting them in their helpless condition.

Subscriptions will be gladly received by any of the committee or by myself.

I am, Sir, yours &c.,
P. M'KENNA, M.B., Hon. Sec.

ERRATA.—The new work on the Teeth, announced in our "Literary Notes" column, last week, as in the Press, by Dr. J. C. Woodburn, of the Glasgow Royal Infirmary, should read by W. D. Woodburn, of Glasgow Western Infirmary. In the annotation on "Newspapers as the Medium for Obesity," the Medical Defence Association should have been Medical Defence Union.

THE DUTIES OF DISPENSARY MEDICAL OFFICERS.

REQUIRER asks.—A. Is it part of the duties of a Medical Officer to (1) a Union Hospital, (2) to a Dispensary, to compound the medicines required?

A. Neither the Poor-Relief Acts nor the Regulations made by the Local Government Board to define the duty of the Workhouse Medical Officer specify the compounding of medicines as part of that duty. In fact, the only duty imposed upon him which might imply the administration of medicine is that which requires him "to give all necessary directions . . . as to the treatment of the sick paupers." Custom, however, in many instances, supports the system of compounding by Workhouse Medical Officers. The Dispensary Medical Officer is required by the Medical Charities' Act (Sec. 9), "to afford medicine and advice." The regulations, however, only impose on him the duty of supplying "all requisite medical and surgical advice and assistance." Nothing is said of medicine nor is it set down anywhere that—in medicines are to be given—they are to be compounded by the Medical Officer.

B. Are Dispensary Committees and Boards of Guardians not required to provide a legally qualified compounder as defined by the Local Government Board?

A. There is no obligatory provision for the appointment of a compounder which is left to the discretion of the Guardians and the sanction of the Local Government Board.

C. Where the Medical Officer is not legally qualified as required by the Local Government Board as a compounder, can the Board of Guardians impose the duties of compounder on him? (This query refers to both Dispensary and Union Hospital Medical Officers).

A. A registered medical practitioner can lawfully compound medicines for his own patients—whether public or private—though he may not possess any special pharmaceutical qualification. Therefore the Guardians may impose that duty upon him if they make it part of his original contract, but, if they have not done so, they cannot afterwards add that function to his duty, nor could he be removed from office if he refused to perform it.

DR. GODDARD.—Your letter has been forwarded to the address of the gentleman referred to.

Meetings of the Societies.

WEDNESDAY, JAN. 15TH.

ROYAL MICROSCOPICAL SOCIETY, (20 Hanover Square, W.)—8 p.m. President Address by Mr. A. D. Michael.

NORTH-WEST LONDON CLINICAL SOCIETY.—8.30 p.m. Clinical Meeting.

THURSDAY, JAN. 16TH.

HÆMATIC SOCIETY.—8 p.m. President's Address and Annual Conversazione.

SOCIETY OF ANÆSTHETISTS, (20 Hanover Square, W.)—8.30 p.m. Dr. Sydney Short, (Birmingham): Observations on a Series of 550 Timed Nitrous Oxide Cases.

FRIDAY, JAN. 17TH.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL AND OTOLOGICAL ASSOCIATION, (11 Chandos Street, W.)—8.30 p.m. Cases, illustrated by microscopic sections, &c., will be shown by the President, (Dr. Stoker), Mr. Mayo Collier, Dr. Pegler, and Dr. Milligan. Mr. Mayo Collier will open a Discussion on the Causes and Consequences of Chronic Nasal Obstruction. Mr. Lennox Browne will read: A Suggestion to Abolish Gargling in the Treatment of Acute Inflammations of the Throat.

EPIDEMIOLOGICAL SOCIETY OF LONDON, (11 Chandos Street, Cavendish Square)—8 p.m. Surgeon-General U. A. Gordon: Experiences in Relation to Cholera in India from 1842-79.

Vacancies.

Birmingham General Dispensary.—Resident Surgeon. Salary £150 per annum (with an allowance of £30 per annum for cab hire), and furnished rooms, fire, lights, and attendance. Applications before the 20th inst. to Alex. Forrest, Secretary.

Bradford Infirmary.—Dispensary Surgeon. Salary £100 per annum with board and residences. Applications endorsed "Dispensary Surgeon" on or before Jan. 27th, to William Maw, Secretary.

City of Dublin Hospital.—Resident Surgeon. Salary £50 per annum, with apartments, light, fuel, and attendance. Applications with copies of testimonials on or before Jan. 18th, to the Hon. Sec. Medical Board, City of Dublin Hospital, Upper Baggot Street, Dublin.

Fabertown House Asylum.—Assistant Medical Officer. Salary £100 per annum, with board, lodging, and washing. Apply to Dr. Finch, the Asylum, Salisbury.

Great Northern Central Hospital.—Junior House Surgeon. Board, lodging, and laundry provided in the hospital. No salary. Forms of application and full particulars may be obtained from Lewis H. Glenton Kerr, Secretary.

London Hospital.—Two Assistant Anæsthetists. Salary £50 per annum. Applications not later than Jan. 18th, to Dr. Munro Scott, Warden.

Margate Royal Sea-Bathing Infirmary.—Superintendent, not necessarily Medical. Salary £150, with partially furnished house and gas. Full particulars on application to the Secretary of the Charity, 50 Charing Cross, London.

Nottingham Children's Hospital.—House Surgeon (non resident). Salary £100 per annum. Applications to be sent to the Secretary by Jan. 20th.

Appointments.

BARRY, J., M.D. Irel., L.R.C.S. Edin., Medical Officer for the Ballydonn Dispensary.

BERRY, WM., J.P., F.R.C.S.I., D.P.H., Medical Officer of Health and Superintendent of the Sanatorium, County Borough of Wigan.

DESPARD, MISS E. C., M.B. Lond., Junior Assistant Medical Officer at the Holloway Sanatorium Hospital for the Insane, Virginia Water.

DONNAN, W. D., M.B., R.O.A., R.U.I., House Physician to the Belfast Royal Hospital.

DUNNAN, M. G., M.R.C.S., Medical Officer by the Mitford and Lanchester Rural District Council.

HARBOUR, GEO. E., L.R.C.P. Lond., M.R.C.S., Assistant Medical Officer and Dispenser at the Infirmary of the Parish of Lambeth.

HODGE, ALBERT, M.R.C.S. Eng., L.R.C.P. Lond., Resident Medical Officer to the Chorlton-upon-Medlock Dispensary, Manchester.

LAKE, J. H., M.B., C.M. Edin., House Physician to the Royal Berks Hospital, Reading.

LEWIS, J. FERGUSON, M.B., C.M. Glasg., House Surgeon to the Hartlepool Hospital.

MAGOWAN, S. M., M.B., R.O.A., R.U.I., Senior House Surgeon to the Belfast Royal Hospital.

MORRISON, A., L.R.C.P. Lond., M.R.C.S., Assistant Medical Officer for the Infirmary of the Parish of St. Pancras.

PATON, H. E. L., L.R.C.P. Lond., M.R.C.S., Medical Officer for the Chudleigh Sanitary District of the Newton Abbot Union.

RUSTON-GARRISON, G. H., M.B., C.M. Edin., House Surgeon to the Royal Berks Hospital, Reading.

SAUNDERS, BERTHA, M.B., C.M. Aberl., Junior House Physician to the North-Eastern Hospital for Children.

TOWRING, J. H., M.B. Lond., L.R.C.P., M.R.C.S., Medical Officer for the Camborne Sanitary District of the Redruth Union.

WALSH, E. P., L.R.C.P., D.R.C.S. Irel., *pro tem.*, Medical Officer for the Enniskillen Union Workhouse.

WILSON, R., L.F.P.S., L.M. Glasg., Medical Officer for the Newchurch Sanitary District of the Haslingdon Union.

Deaths.

MINTER.—On Jan. 5th, at Mansion Row, Chatham, the wife of Ernest D. Minter, Surgeon R.N., H.M.S. *Esper*, of a son.

MOLSON.—On Jan. 7th, at 13 Lingfield Road, Wimbledon, the wife of J. Cavendish Molson, L.R.C.P. Lond., of a daughter.

OLIVE.—On Jan. 7th, at Leamington, the wife of Eastace J. P. Olive, M.A., M.D., F.R.C.S., of twin daughters.

VOELCKER.—On Jan. 8th, at 31 Harley Street, London, the wife of Arthur F. Voelcker, M.B., of a daughter.

Marriages.

CLARK—MATTHEWS.—On Jan. 8th, at St. Paul's, New Beck enham Arthur Deeshoroug, L.R.C.S., L.R.C.P., son of the late Thomas Clark, of Beckenham, to Annie Rutherford, only daughter of George Kelly Matthews, of Beckenham.

JONES—WOODMAN.—On Jan. 7th, at Christ Church, Forest Hill, Wilfred Edward Jones, M.R.C.S., L.R.C.P., second son of C. Sturgeon-Jones, M.R.C.S., of Chichester, to Eileen Beaks, third daughter of William Woodman, of Woodbank, Forest Hill.

NIAS—DAYKELL.—On Jan. 8th at St. Jude's Church, South Kensington, Joseph Baldwin Nias, M.D., eldest son of the late Admiral Sir Joseph Nias, K.C.B., to Frances Miriam Clare, second daughter of Captain Edmund Dayrell, R.N.

Deaths.

DIXON.—On Jan. 3rd, at Harrow Lands, Dorking, James Dixon F.R.C.S., aged 82.

HILTON.—On Jan. 4th, at Milestone House, Upper Deal, Thomas Dennis Hilton, M.R.Osantab, aged 74.

LOMAS.—On Jan. 3rd, at Belper, Henry Lomas, L.S.A., in his 92nd year.

MAY.—On Jan. 2nd, at Bournemouth, W. Costall May, M.R.C.S., late of South Kensington aged 66.

Lectures

ON

THE DIAGNOSIS OF INSANITY.

By THEO. B. HYSLOP, M.D.,

Lecturer on Mental Diseases to St. Mary's Hospital Medical School,
Assistant Physician to Bethlem Royal Hospital.

LECTURE IV.

In this lecture I propose to deal with some additional factors which either tend to predispose towards or modify attacks of insanity. Considered *seriatim* these factors are:—

(5) *Habits of Life*: (a) intemperance in alcohol, (b) sexual excesses, (c) excessive meat eating, and other dietetic irregularities, (d) irregularity as to sleep and bodily hygiene, non-cultivation of control, &c.

(6) *Periods of Life*: birth, dentition, infancy, puberty, adolescence, maturity, pregnancy, puerperium, dimacterium, and senility.

(7) *Previous Illnesses*: fevers, malaria, rheumatism, gout, rickets, syphilis, scurvy, struma, tuberculosis, cancer, anæmia, chlorosis, diabetes, goitre, &c.

(8) *Accidents or Injuries*: shocks, wounds, local injuries, sunstroke.

(9) *The Effects of Drugs*: alcohol, opium, haschisch, belladonna, chloroform, ether, lead, &c.

Alcohol undoubtedly produces far-reaching effects upon the exquisite structures of the brain, and consequently upon the mental faculties which these structures subserve. The derangements due to alcohol may be mainly sensory, motor, or intellectual. Alcohol may produce a temporary disturbance of the intellect by means of its direct poisoning influence on the brain, or it may cause structural alterations of the brain which are characterised by progressive weakening of the mental faculties, and finally dementia. The symptoms of direct poisoning are doubtless well known to all; the features of slow decay of the brain and mind will be dealt with later.

The main types of alcoholic insanity are as follows:

(1) The purely sensory types in which there is perversion of the common, visceral, or special senses. Perhaps one of the most common causes of delusional insanity is alcohol. Not infrequently recurrent attacks of alcoholic mania ultimately pass into delusional states with ideas of persecution. Several patients now in Bethlem are of this type, they have been admitted and re-admitted suffering from the effects of intoxicants from which they have recovered. Sooner or later, however, there has come a time when sensory disturbances have predominated and these followed by delusions of persecution have rendered the cases incurable and destined to remain for ever under asylum supervision. (2) *Motorial types*, in which the intoxicant affects the motor apparatus, are also very common, and it is with these cases that the greatest number of mistakes in diagnosis are made. Not infrequently persons suffering from tongue tremors and inability to co-ordinate movements are diagnosed as general paralytics. They may be suffering from general paralysis, but it is better to give a provisional diagnosis and state that the effects, if due entirely to alcohol, may pass off and end in recovery.

Sometimes it is difficult to obtain a history of alcoholism. The wives of commercial travellers and city men have never seen their husbands intoxicated, and possibly they may not have been really so; nevertheless, they have been accustomed to drink copiously and constantly so that their brains have become predisposed to break down under some other exciting cause. Sometimes such individuals are keenly conscious of their motor unsteadiness, and resort to "a hair of the dog that bit them" to regain stability. Cases in which there are marked tremors on admission and which appear to increase during the next few days are always suggestive of alcoholism, and more particularly so if subsequently they tend to disappear. In this relation it is of the utmost importance to remember that alcohol may produce temporary disturbance of the cerebro-spinal system which cannot be distinguished from general paralysis with spastic or ataxic symptoms. (3) Alcohol may produce very varied mental defects. The chief defect is impairment of memory. The impairment may be primary and progressive in nature, leading to a condition of dementia. Some observers believe that amnesia is the earliest evidence of structural change in the brain, and that absolute recoverability is rarely (if ever) obtained in this stage of alcoholism. This, however, is an opinion which we are unable to confirm, and I believe we are not warranted in giving an unfavourable prognosis solely from the consideration of a defective memory. In alcoholic insanity, just as in other forms of insanity, the memory is liable to be temporarily affected; and at present we are not well enough acquainted with the laws of memory to be able to definitely prognose as to curability. In old standing cases in which there is complete failure to re-educate the memory, and in senile cases, we may be able to give an unfavourable prognosis; but I repeat that, in acute cases it is wiser to give a provisional diagnosis. The more one sees of alcoholics the more one realises that to them all things appear to be possible, even recovery from the lowest depths of degradation.

Alcoholic insanity is most apt to supervene during the periods of activity when there is the greatest amount of wear and tear. Thus it is more commonly met with between the ages of 25 to 30 and 35 to 45. It has been estimated that 37·2 per cent. of alcoholics are predisposed to it by inheritance. Sometimes children have a morbid craving for alcohol. In nearly all the types of alcoholic insanity the most noticeable feature is that of impulsiveness. Subsequently, however, we shall devote more attention to the varieties of morbid impulse associated with epilepsy and other neuroses, cranial injuries, syphilis, sunstroke, &c.

Hallucinations may be visual, aural, general, systemic, visceral, or relating to the senses of smell or taste. One alcoholic patient in Bethlem used to believe that his legs were being bitten by fishes, the belief arising in connection with a cutaneous patch of hyperæsthesia. Others imagine themselves to be persecuted by electricity, &c., owing to some cutaneous disturbance. The other features of alcoholic insanity will be dealt with more conveniently when we come to consider the points of differential diagnosis between general paralysis and other forms of insanity.

Sexual excess is undoubtedly a cause of some forms

of mental disorder, while in others it is merely a symptom of a predisposition or nervous instability. The husbands of amatory and voluptuous women are not infrequently the victims of general paralysis. It is important to note, however, that, although it is fairly certain that sexual excess does cause general paralysis, yet there are some cases in which the sexual excess is a symptom and not a cause. I have seen a man who, during his adolescence and manhood, had led a temperate life sexually, yet who, when he got on in years, became unstable and developed a tendency to excessive venery, which was regarded rather as a symptom of early senility than a cause of the morbid mental symptom. Another patient, formerly in Bethlem, broke down after exposure to a tropical sun, and developed an ambition to get black babies, which ambition he pursued to the point of extreme exhaustion and mental ruin. Although some authors maintain that sexual excess is almost invariably a cause of general paralysis, it is fairly evident that in some cases, at least, there has not been any sexual excess. Masturbation seldom causes it. The influence of sexual excess in the production of mental diseases is very difficult to estimate correctly. In adolescents the disorder is usually characterised by certain well-marked features. The individuals are usually dull, phlegmatic, and lacking in energy, they hold themselves aloof from others, and may be seen sitting in a corner with their hands lying between their thighs. The dull look and the obvious sluggish circulation are fairly constant characteristics. Unfortunately, patients of this class are exceedingly apt to degenerate and become demented. Their delusions are commonly connected with the sexual organs, and not a few of them have perversions of taste and smell. A person of the above type, who complains of pain in the back of his head, foul smells or tastes, and delusions as to sexual persecution is generally a masturbator. In my experience such cases seldom recover. They may improve up to a certain point, but ultimately they tend to become demented. Impulsiveness is also a common symptom, and in my opinion the development of impulsive tendencies in such cases is a very unfavourable omen. Dr. Skæ has graphically described this vice as producing a group of symptoms which are quite characteristic and easily recognised, and give to the case a special natural history; the peculiar imbecility and shy habits of the very youthful victim; the suspicion, fear, dread, suicidal and other impulsive tendencies, the palpitations, scared look, and feeble body of the older offenders, passing gradually into dementia or fatuity.

The influence of diet in the production of mental diseases can scarcely be over-estimated. Insufficient nutritive substances, irregularities in the habits of feeding, injudicious diets, and other strains upon the digestive organs are extremely apt to disturb the cerebral circulation, and consequently the nutrition of the cortical structures. Insufficient food during early life has been assigned as the cause of imbecility and idiocy. At the present day there is considerable uncertainty as to the origin of some of the scorbutic types of imbeciles and idiots in our asylums, and we do not as yet know the relations between scurvy and rickets and mental defects. Not a few of these types are difficult to estimate, and more especially so when no hereditary tendency can be traced. Dr. Cheadle was one of the first to point out to the medical world the clinical affinities of infantile scurvy. Seventeen years ago he published his investigations upon cases of scurvy supervening on rickets in young children, and later some important observations on osteal and periosteal cachexia and scurvy. There are still, however, many observations wanted upon these subjects. We do not know whether the acute rickets of the German authors, which is now commonly regarded as a combination of

scurvy and rickets, is in reality a combination; and, if so, whether the scurvy is an essential and the rickets a variable element, or *vice versa*. The points of difference between infantile and adult affections are not clearly defined. No explanation has been offered, although frequent mention has been made, of the hysterical objection to vegetable diets in these cases. The fainting fits reported as occurring in association with these cases are of doubtful nature. It would also be of great value to have some definite information as to the value of Swiss milk, Nestlé's food, Robb's biscuits, Liebig's extract, and other preparations, which at present appear to be household words to the possibly uninitiated. At present we do not know what proportion of children fed on these foods have faulty nutritional changes.

In adult life the peculiar distribution of general paralysis has been thought to be due to variations in diet. The large consumption of potatoes in Ireland, and of oatmeal in Scotland, has been regarded as a cause of exemption from general paralysis. Whether the peculiarities of diet are the causes, or whether the influence of syphilis, sexual excess, and alcohol are the chief factors, we are at present unable to determine.

Excessive meat eating is sometimes assigned as a cause of general paralysis, but this is a conjecture which we are unable to verify. Commercial travellers and others who are liable to take their meals at irregular intervals, and who freely indulge in nitrogenous diets, not unfrequently become general paralytics.

Insomnia is undoubtedly one of the most common of the causes of insanity. Loss of rest and failure to recuperate cerebral energy has insidious and far-reaching effects, which may lead to temporary mental instability or even to total dementia and death. Eighty per cent. of the cases admitted to Bethlem have suffered from want of proper sleep.

I now propose to mention some of the *physiological periods of life* which are most fraught with danger to an individual. During *infancy* various forms of idiocy and imbecility may arise. The causes acting at birth may be, premature birth, difficult labour, instrumental delivery, accident, asphyxia neonatorum, or primogeniture. Those acting subsequently to birth may be, infantile convulsions, epilepsy, cerebral affections, febrile disturbances, paralytic affections, sunstroke, nervous shock, or physical injury to the head.

Among the more important factors which determine mental defects or aberrations in the infant, we have to note the following structural abnormalities of the brain and spinal cord:—(a) Anencephalus in which the vault of the cranium is absent, the base being occupied by a mass of connective tissue and blood vessels, formed from outgrowths of the pia mater; (b) absence of the proencephalon in which there is a rudimentary thalamocephalon, the cerebellum, pons, and medulla, being reduced in size owing to the absence of development of the proencephalic fibres; (c) cyclops, in which there is an undivided anterior cerebral vesicle occupied by only one ventricle, and in some cases the presents, of only a single optic nerve and a single eye.

Other abnormalities of the brain and spinal cord have been grouped as follows:—

(1) Abnormalities accompanied by defects in the envelopes of the part:—

(a) Cranioschisis:—
Encephalocele.
Hydrocephalocele.
Meningocele.

(b) Rachischisis:—
Myelocele.
Meningocele spinalis.
Spina bifida occulta.

(2) Abnormalities in which the envelopes are entire:—

Hydrocephalus.

- Microcephalus.
- Porencephalus.
- Hypertrophy.
- Aberrant arrangement of fissures and convolutions.
- Agenesis of cortical elements, commissures, and associative tracts.

Of the various types of congenital and acquired imbecility which may be diagnosed during infancy, we have to note the following:—

(1) Congenital, in which the individual is usually of a low type, with a tendency to physical weakness, strabismus or nystagmus, a highly arched or elongated palate, also automatic movements, contractures, or spastic rigidity. Such patients not uncommonly slaver, and appear to be incapable of caring for themselves. Their special senses may be defective or only partially developed, and there may be little or no power of attention or volition.

The types of congenital imbecility have been classified as follows:—(a) Simple congenital, which include those forms without any obvious physical deformity of the head or limbs. The Mongol or Kalmuc idiot belongs to this class. A typical Mongol idiot, however, is usually of stunted growth and brachycephalic. His fingers and hands are short and dwarfed. Their defective circulation and inability to resist acute diseases usually incapacitate them from attaining to adult age.

(b) Microcephalic, in which the brain has ceased to grow, due either to some internal cause or to the premature closure of the sutures of the skull. As a general rule, heads below 17 inches in circumference are held to be too small for ordinary intelligence.

(c) Hydrocephalic, in which the fontanelle is raised, the head is globular, with the widest circumference at the temples, and occasionally a slight bulging above the superciliary ridges. (d) Scaphocephalic, in which the head is keel-shaped. (e) Paralytic, in which there is arrest of development of part of the brain, due to injury, disease, or apoplexy. In such cases the mental powers can sometimes be cultivated to a certain extent, but the physical development is locally arrested. Usually one hemisphere only is affected.

(f) Cretinism, which may be sporadic or endemic. The types of acquired imbecility are as follows:—

(a) Eclamptic, in which there is arrest of development of the mental functions due to the occurrence of convulsions soon after birth, and which have damaged the structures of the brain. (b) Epileptic, in which, as the result of frequent fits, the intellect becomes dull, and the individual becomes incapable of advancing intellectually. (c) Paralytic, in which the paralysis is acquired at some period after birth. Some of the cases are due to the occurrence of fits, or to cerebral apoplexy. (d) Inflammatory, is usually a sequel to some acute illness, such as measles, typhoid, whooping-cough, sunstroke, &c. The amount of impairment of the mental faculties depends in great part upon the amount of damage to the brain-tissues. (e) Hypertrophic, which may or may not be associated with rickets. Usually, the brain is not so large as in hydrocephalus. The head is somewhat square and bulges above the superciliary ridges. Hypertrophy is said to differ from hydrocephalus in the fact that in the former there is no elasticity over the late closed fontanelle as in the latter. In hydrocephalus the distance between the eyes is increased; in hypertrophy this is not the case. (f) Traumatic, due to a fall or blow on the head. Sometimes the injury has caused the occurrence of fits which serve to prevent mental improvement. (g) Endemic cretinism, in which there are none of the fatty tumours in the posterior triangle of the neck like those found in sporadic cretinism. Usually, cretins are classified according to their degree of development. The lowest types are termed "cretins"; those with a certain amount of intelli-

gence "semi-cretins"; while those who have a fair amount of mental power are termed "cretineus."

Insanity is rare in early infancy. It occurs in children who have a strong neurotic inheritance, and manifests itself by terrors, nightmares, nocturnal delirium, and visual hallucinations. Some children have morbid and often dangerous impulses. Attacks of melancholia or of mania are rare. Night terrors usually occur an hour or two after going to sleep. The attacks are characterised by excessive fears, screaming, and usually some terrifying hallucinations. They occur in children of a neurotic, scrofulous, or anæmic type. The immediate exciting causes may be indigestion, worms, teething, enlarged tonsils, ear disease, catarrh of the respiratory passages, irritation of the skin, ill-ventilated bedrooms, fevers, or to various conditions of mental excitement during the day. The attack may be idiopathic, in the form of a transitory hallucination of sight, due to increased irritation of the brain cortex, or symptomatic, as a reflex neurosis of the pulmonary vagus resulting in dyspnoea, and thereby in a sensation of subjective terror. It is not common for night-terrors to be associated with organic brain disease or with epilepsy. Occasionally, however, children affected with night-terrors become epileptic. One case has been reported in which night-terrors took the place of epilepsy.

Dreams, nightmares, and somnambulism occur in children, due to causes similar to those of night-terrors. Over-fatigue or nervous excitement during the daytime tend to produce these affections, and, as the consequence, there is imperfect brain-rest with its disastrous sequelæ. Of the other factors which determine an attack of insanity in a child, we shall take account in the next lecture.

POST-GRADUATE CLINICAL DEMONSTRATIONS.

By JONATHAN HUTCHINSON, LL.D., F.R.S.,
F.R.C.S.,

Consulting Surgeon to the London Hospital, and late President of the
Royal College of Surgeons, England.

[Specially Reported for the MEDICAL PRESS
AND CIRCULAR.]

AMONG the cases recently illustrated by Mr. Hutchinson at his Clinical Museum was an interesting one of
**DESTRUCTION OF THE SOFT PALATE, OF DOUBTFUL
ORIGIN, IN A BOY.**

The boy who was in fair health, was 8 years of age, and had lost the greater part of his soft palate. The point of chief interest in the case was whether or not he was the subject of any taint of inherited syphilis. The history showed that the disease had been two years in progress, it was, therefore, slow, and nothing of a phagedænic nature had ever been present. Thus its persistence was against the diagnosis of lupus, for, had the disease been lupus, the duration of the case would not have been so long. Two years ago the patient suffered from synovitis of both knees—that is hydrops articuli. The effusion lasted for six months, was unaccompanied by pain and was followed by complete recovery of the joints. The joints were now quite healthy. It was of interest to note that in cases of inherited syphilis effusion into the knee-joints was of common occurrence. It usually occurred about the same time as the interstitial keratitis. But the patient's eyes were quite healthy, and he had no interstitial keratitis nor choroiditis. His teeth, moreover, were large and good, and neither mercurial nor syphilitic. That, however, would be likely to be the case provided that he had been healthy as an infant. As a matter of

fact his mother stated that he had been quite well during infancy, and had not required any medicine. Mr. Hutchinson differentiated between the effusion into joints the result of inherited syphilis and that due to a rheumatic cause. In the former there was no pain and perfect recovery followed without any relapses, while in the latter pain was always present, and secondary changes occurred in the joints. The boy's face was not suspicious of syphilis; and although the head was "a little lumpy," there was nothing which anyone could, in this respect, be certain about. Some enlarged glands were present under the jaw. Mr. Hutchinson, upon the whole, regarded the diagnosis as an open one. His suspicion, however, was in favour of syphilis. The boy had been better since taking iodide of potassium. But if interstitial keratitis were to develop, the diagnosis, of course, would be set at rest.

The next case was that of a woman suffering from a
RELAPSING SORE TONGUE.

There were large abraded patches upon the surface of the organ and these resembled a severe attack of herpes. Herpes of the tongue occurred chiefly along the margin and tip; herpes of the tip was exceedingly common. Sometimes these attacks supervened with such frequency that the patients were scarcely ever free from them. The history of the present case was that the disease had persisted off and on for twenty years. At intervals the tongue would be quite sound, but after some months a relapse would occur. The present attack, which had lasted for four months, was the most severe which the patient could remember. On examination of her teeth, one tooth was seen in which an amalgam stopping had been used. Mr. Hutchinson here remarked that he entertained great prejudice against amalgam stoppings in teeth, especially in mouths which were sore. In such cases he always insisted upon the amalgam being removed and gold inserted in its place. Dentists, he stated, would not believe that any harm arose from amalgam stoppings. But he was satisfied that in certain conditions some chemical solution of the amalgam took place. Most often the tongue became sore opposite the tooth in which the amalgam was present. Moreover, he had often found that patients could tell by means of a slight metallic taste in their mouths which tooth it was in which the amalgam had been placed. Again, he had often seen cases of sore mouth where all the symptoms had been relieved by replacing the amalgam with gold stopping. The pellicular condition of the patient's mouth was most interesting. In some respects the leucophakia somewhat resembled that seen in smoker's tongue, but more inflammation was present than was usually observed in the latter condition. It was worthy of note that the filiform papillæ had disappeared over a large area. The patient, on being asked if any particular articles of diet caused irritation to her tongue, replied that anything "sharp" did so, and in this connection she instanced vinegar. She also avoided walnuts. Mr. Hutchinson was interested to find that she had herself discovered the irritating effect of walnuts. He pointed out that walnuts were especially harmful in these cases. The old dry walnuts were possibly not much to be blamed in this connection, but the juice of the rind of the young moist walnuts was especially irritating. He had seen many cases of sore mouths arising from this cause. Again, such patients should avoid all effervescing waters, and sugar in combination with vegetable acids was very harmful. The remedy for these cases was arsenic.

His next case was a very interesting one of

DOUBLE INCOMPLETE PARALYSIS OF THE THIRD NERVE.

The patient was a lad, *æt.* 10. Mr. Hutchinson

pointed out the sleepy aspect which the drooping of the lids caused. The boy instinctively thrust his chin forwards and wrinkled his brow in order to try and overcome the effects of the ptosis. Besides the double incomplete ptosis there was double divergence, more marked on the left than on the right side, owing to weakness of both internal recti muscles. It was evident that certain branches of the third nerve were involved, but it was also clear that some of the branches were unaffected, inasmuch as the pupils were of normal size, and freely active to accommodation and light. The other recti muscles were normal. The case, Mr. Hutchinson observed, was a very curious and interesting one. There was nothing in the boy's history to throw any light upon its etiology. No evidence could be produced showing an inherited syphilitic taint. The main features in the onset of the attack were that about three weeks before he came under notice he was suddenly seized with severe pains in his head, and seven days later the paralytic signs appeared. At first he was supposed to have had diphtheria, but this appeared to be negated by the fact that the movements of the palate were free, and that there was no nasal voice. The patient could fix with either eye, but he usually looked with the right. His tongue was clean, his appetite good. He could walk quite well. His head was occasionally painful; he did not complain of sickness. The etiology of the case was very obscure.

KAPOSI'S DISEASE.

The patient was a little girl, *æt.* 8, the youngest of three sisters; she was quite well until two years of age, and then the signs of Kaposi's disease, from which she was now suffering, began. Xeroderma pigmentosa—which was another name for this disease—was a rare malady. As a rule, it became manifest early in the life of the patient. It was due to congenital weakness of the tissues, which could not stand more than a certain amount of stimulation by sun-light. Cases were sometimes met with in which the whole body was affected. It was a family disease, almost always attacking three or four members of the same family. Its first stage was one of extensive freckling, affecting the face and hands. Next followed a stage of ulceration, and bossy masses of granulation grew out; and, finally, there was a strong tendency to develop fungating masses, which were of the character of epithelial cancer. In most of these features it had close parallels to certain cases of lupus. A point of some interest in the present case was that the patient was the offspring of a consanguineous marriage. In that respect there was some parallelism between it and cases of retinitis pigmentosa, in which a history of consanguineous marriage was not infrequently to be obtained. But Mr. Hutchinson stated that he had never seen Kaposi's disease associated with retinitis pigmentosa, and it was probable that the cases were quite distinct. In cases of retinitis pigmentosa the retina began to take on pigmentation from exposure to light, in other words, the retina became freckled, mainly at first at the periphery, the pigmentation, however, extended, and gradually approached the yellow spot region, and at about early middle life much loss of vision was the result. So far as treatment was concerned in Kaposi's disease, a great deal could be done by protecting the skin with some ointment, and by keeping the patient out of the sun. It was worthy of note that the disease was the same in all climates.

THE West London Hospital has been recognised as a place of study during the fifth year of the curriculum by the Council of the Royal College of Surgeons, England.

ON
CHILDREN'S SPINES:
HEALTHY, UNHEALTHY—AND
OTHERWISE.

By EDMUND OWEN, M.B.LOND., F.R.C.S.,

Surgeon to St. Mary's Hospital Senior Surgeon to the Hospital for Sick Children, &c.

THE author (a) directed attention to the great range of movement possessed by the spine of the healthy child, demonstrating its extent by diagrams and photographs, which he had prepared from various pictures and statues in galleries of ancient and modern art. He then showed photographs of children who had been under his care for tuberculous inflammation of the vertebra, calling attention to the fact that in every such case the first symptom of the disease was stiffness. After duly discussing the need of having the child stripped naked before attempting to examine the back, he urged that the medical attendant should be constantly on the look-out for the occurrence of suppuration, as abscess often approached the surface of the chest, the loin, or the groin, without giving any warning of its formation. Such abscesses were best treated by incision, erosion, and immediate suturing. It was a mistake to use a drainage-tube unless the subsequent course of events showed that its presence could not be dispensed with. As regards the value of laminectomy in those cases in which paraplegia followed collapse of the vertebra, Mr. Owen said that it had at first been sadly over-estimated. He gave clinical records of paraplegic cases in which he had refrained from interfering, and had been rewarded by slow but steady return of the power of locomotion. In one of these cases there had been motor paralysis in the upper extremities as well as the lower, and paralysis also of the intercostal and abdominal muscles. He compared the operation of laminectomy with the heroine of the modern society-drama, in that it had a discredited past and a hopeless future. He had a good deal to say about a class of children whose spines he declined to regard as "diseased," though other practitioners refused to consider them healthy; so, with the view of avoiding unpleasantness, he placed them in a special class, calling them "otherwise." He insisted that too much fuss was being made about a slight lateral deviation of the spine of a growing child. People, it seemed, were inclined to look at a child's spine, to speak, and to write of it, and also to treat it as if it were something apart from the child itself. And he delicately hinted that such impressions were apt to engender a species of irregular practice. He instanced a case in which a practitioner had advised a lady to place a younger child—whose back the said practitioner admitted was quite healthy—under his prolonged and close supervision, lest this healthy child should ultimately acquire a deflected spine like that of its elder brother! He thought that such "prophylactic" treatment of healthy spines was an unworthy occupation for a surgeon, and, quoting George Eliot, he remarked that medicine should be honoured as a profession but despised as a trade. He thought that if medical men occupied themselves too exclusively with the treatment of slight deflections of a limp spine their surgical vision was apt to become distorted, and that they were likely to lose the necessary sense of perspective and proportion. He reported another case of a weak-spined child whose mother had been terribly alarmed by what had been told her by a gentleman whom she had consulted in reference to it. This gentleman had told the mother that her child must at

once come into lodgings near him for exercises and treatment or he would not be responsible for the consequences. Mr. Owen had not been able to find much wrong with the spine; but the mother had apparently been made to think that unless the child were at once taken in hand she would grow up into a woman somewhat like that described by Burns:—

"She's twisted right, she's twisted left,
To balance fair in ilka quarter:
She has a hump upon her breast,
The twin o' that upon her shouther—
Sic a wife as Willie had,
I wadna gie a button for her."

Presidential Address

AT THE ANNUAL MEETING OF
THE BRITISH GYNÆCOLOGICAL SOCIETY.

By CLEMENT GODSON, M.D.,

Consulting Physician to the City of London Lying-in Hospital and late Assist-Physician Accoucheur to St. Bartholomew's Hospital, Physician to the Samaritan Hospital for Women.

AFTER thanking the Society for the honour bestowed on him by his re-election as President, he referred to the fact that during the past year no less than ninety-three new ordinary Fellows had been added, which was the greatest number elected in any one year since the society was founded. They had also elected two Honorary Fellows—Professor Leopold, of Dresden, and Dr. Lombe Atthill, of Dublin.

He then referred to the losses by death the Society and the profession at large had sustained during the year. By the death of Dr. Thomas Keith, on October 9th, he was reminded of the great influence for good which he brought to bear upon the development and perfection of abdominal surgery. His name must for ever live as one of the greatest of British ovariotomists. He next alluded to Robert Battey, of Rome, Georgia, U.S.A., who died at his home on November 8th last. Battey was a country practitioner, who after much thought and consideration, performed oöphorectomy in a case of pronounced neurosis. He fully explained his methods and reasons; and, while it is admitted that nowadays such operations can only very rarely be justified, there can be little doubt but that Robert Battey deserves to rank as a pioneer in modern gynecology. Another Fellow of the Society who had passed away was Henry Widenham Maunsell, M.A., M.D., (T.C.D.) They would miss him in their debates; his strength of argumentative power was evidenced in his remarks on "The Extra-peritoneal Method of Dealing with Uterine Myomata" at the meeting on Feb. 25th, 1892, which he concluded in these words. . . . "It is my opinion that extra-peritoneal myomectomy should be at once, and for ever, abandoned, as it is a disgrace to the surgery of the latter end of the nineteenth century; and all forms of uterine clamps, pedicle skewers, and wire écraseurs should be forwarded without delay to a museum for antiquated and barbarous surgical instruments." Maunsell was an apt and ingenious surgeon who instituted various novel procedures, especially in connection with intestinal surgery. Mr. Hugh Thomas, of Birmingham, M.R.C.S.Eng. and L.S.A., who was a life Fellow of our Society, died at his residence, Grange Road, Coventry Park, on May 23rd last. He was a past President of the Queen's College Medical Society, the author of "Uterine Hydatids" (1883), besides many contributions to the medical journals. Dr. Robert Alexander Jamieson, of Shanghai, was born in Cork in 1842, and died at Shanghai in 1895. In 1869 he was appointed Medical Officer to the Imperial Chinese Maritime Customs, and edited the Customs Medical Reports. Dr. Patrick Manson tells me that through this medium together with many

(1) Abstract of paper read before the Harveian Society of London, Jan. 8th, 1896; President, Sir John Williams, Bart., M.D., in the Chair.

excellent papers on disease in China he contributed very largely to our knowledge of diseases of the East.

The President then proceeded to review the work done by the Society during the past year.

At the March meeting, Dr. Macnaughton-Jones contributed a paper on "The Dangers of Morphia in Gynecological Practice," showing forcibly the disastrous effects produced by the abuse of one of the most useful of drugs. The paper displayed great labour and research in the literature of the subject, and was considered so important that the discussion upon it was adjourned to the next meeting, when several visitors, distinguished specialists in mental diseases, took part in it. At the May meeting, a most important paper was read by Dr. Michie, of Nottingham, on "Pregnancy complicated by Suppuration within the Pelvis." He related six cases which had come under his observation. He divided them into three groups, the first, perforation of the vermiform appendix giving rise to abscess extending into the pelvis, of which he had only one example, operated upon by him at the end of the fourth month of pregnancy; the second group, where suppurative peritonitis had been set up shortly before or during delivery, and having its origin probably in pre-existing disease of the uterus or its appendages, of which he gave two examples, both of pyosalpinx which gave rise to puerperal peritonitis, in both of which he opened the abdomen and found in the peritoneal cavity a quantity of thin offensive pus which was proved to have escaped from the Fallopian tubes. Of the third group—suppuration of the appendages operated upon during pregnancy, *i.e.*, before delivery—he gave three cases. In my remarks during the discussion on this paper I mentioned a case identical in the symptoms to those of the second group:—A lady, well-known in the fashionable circles of London, who when she asked me to attend her in her first confinement, told me she had been laid up in Italy soon after her marriage with some inflammation about the womb, and had suffered pain in the lower abdomen more or less ever since. She was confined in December, 1890, and I saw her on account of this pain frequently before she was taken in labour. She had a natural labour, conducted by myself on the most strict antiseptic principles, as explained by me in a lecture on Antiseptic Midwifery, delivered at the Midwives' Institute and Trained Nurses' Club in 1887. In less than 30 hours after her delivery she was seized with acute abdominal pain; distension of the abdomen, with great tenderness, ensued, with rise of temperature and vomiting. She was seen by several eminent physicians in consultation with me, all of whom agreed that she was suffering from septic peritonitis. It was only towards the end that a surgeon, a friend of the family, Mr. Astley Bloxam, was asked to meet us to consider if any surgical operation might be undertaken. Abdominal incision and flushing out the peritoneal cavity was discussed by us, but the tympanites was so great, and the patient almost moribund, so it was decided not to operate. She died on the eighth day after delivery. I have never ceased to regret that Mr. Bloxam did not see her at the commencement of the illness, when I feel convinced, had her abdomen been opened, a similar condition to that recorded by Dr. Michie, in his second group, would have been found, and the patient possibly might have been alive now. Fashionable London said she died of puerperal fever, and the husbands of all the ladies of this circle that I was about to attend politely intimated to me that they would not like me to do so, and no wonder. There were two patients, however, not cognisant of the occurrence, and these I had no hesitation in attending, and, needless to say, no fever was communicated to them: they did perfectly well, and I have had no case of puerperal illness in my practice since. The loss of this patient did my obstetric prac-

tice serious injury for a time. I have hopes that Dr. Michie's paper, following that of Dr. Grigg, read at this Society in November, 1890, recorded in Vol. VI, No. 24, of the *British Gynecological Journal*, may demonstrate the importance of early surgical interference in cases of puerperal peritonitis, and that they may be recognised as distinct from puerperal septicaemia arising from absorption of septic matter from without, the symptoms of which widely differ.

At the June meeting the subject of curetting the uterus was brought forward in the form of a paper for the first time before this Society by Dr. Fancourt Barnes, under the title of "On Some Difficulties in the Use of the Curette." He concluded by submitting five questions: 1. What are the symptoms which point to the clear necessity of curetting the uterus? 2. Which is the safest and most natural method of dilating the cervix? 3. Should the curette be used in cancer of the uterus—more especially when the growth is at the fundus? 4. Is it advisable to resort to the use of the curette as a means of making a diagnosis? 5. Is it possible to establish a satisfactory system of drainage of the uterine cavity after curetting? Surgeon-General Harvey, Professor Japp Sinclair, Mr. Greig Smith, and Mr. Christopher Martin took part in the discussion, which was adjourned to the next meeting.

At the October meeting Mr. Jessett contributed an instructive paper—"Suggestions for Performing Abdominal Hysterectomy by Total Extirpation of the Uterus." This, with the notes of eight cases operated upon by him, and illustrated by excellent sketches, showing the several stages in the operation, will be found in the November number of the *Journal*.

At the November meeting a valuable paper by Dr. J. Halliday Croom on "Glycosuria Complicating an Ovarian Tumour, and Ovariectomy," was read. (Published in *THE MEDICAL PRESS AND CIRCULAR*, December 4th, 1895.) The subject is one of importance to general practitioners as well as to gynecologists, and will well repay future study.

The President next referred to the many instructive specimens that had been exhibited during the past year, all of which have been recorded in these columns. He concluded this portion of his address by referring to the last meeting of the Society, December 12th, when Dr. Smyly, of Dublin, showed some very interesting specimens—one a pyosalpinx removed by vaginal colotomy, and three myomatous uteri removed per vaginam by morcellement—the results in all being apparently excellent. A discussion, in which Dr. Bantock took a warm part, as to the relative merits of the removal of such by abdominal section, or per vaginam ensued, and he thought it would be well if the subject were brought up again during the ensuing year for discussion.

The President next congratulated Dr. Leith Napier and thanked him on behalf of the Society for the great improvements he had wrought in their journal as editor, and which had become a permanent record of the good work of the Society. Since the last annual meeting an American edition of the journal had been established, which primarily involved the Society in additional expense, but there would now be a substantial gain to the funds by the arrangement which had been made with the American publishers.

In conclusion, he urged upon the Fellows the great importance of regular attendance. Those who had not time to write papers, nor had material in the shape of specimens to exhibit, might take part in the discussions; or, if they did not care to speak, they could not fail to profit by being present. One had only to look through the list of Fellows to see what a strong Society it had become. It should be second to none in the attractiveness of its meetings. There was, he considered, a sociable body, with no petty jealousies.

They did not profess to be better than their neighbours, but they endeavoured, by upholding all that is noble, by suppressing everything that is dishonourable, and by the earnest character of their work, to maintain a high place among the learned Societies.

Clinical Records.

A CASE OF PARA-UTERINE AND PARA-VAGINAL TUMOUR EXTENDING INTO THE LEFT BUTTOCK.

By Mr. FRED. EDGE, F.R.C.S.,

Gynaecological Surgeon to the Wolverhampton Hospital for Women.

Mrs. C., *æt.* 35, married 11 years, came to me on June 18th, 1894. Some three or four years previously she had seen Mr. Lawson Tait. She began to menstruate at 13, has been regular every 28 days, lasting one day, and accompanied by sharp pain for about three hours on left side. The loss was always scanty. She has had no children nor abortions.

Physical Examination.—*General.*—Patient is a well-nourished sound woman, with no perceptible disease of general systems.

Local.—The left labia and the tissues overlying the ischio-rectal fossa are bulged out evenly to a marked extent. The bulging is firm and not nodulated, and can be pushed inwards and upwards. There are no signs of inflammation. The vulva is displaced to the right, and is convex to right from before back. The finger *passes into vagina* over rounded surface bulging left vaginal wall inwards and forwards, and implicating lateral and back part more than anterior part of vagina. Vagina is narrow and rugæ marked. The cervix is high up, is elongated, slightly pointed, and has distinctly rounded small os. The uterine sound is deflected to right side; uterus normal in length. The appendages are not to be made out, nor the upper part of uterus, since parietes are tense and fat. The para-vaginal mass feels slightly fluctuant or yielding.

Per Rectum.—The large fluctuant tumour is well-defined and lies on the left wall of the pelvis, running as high as the uterus and not to be defined above. On combined rectal and vaginal examination the tumour feels rather fluctuant.

The diagnosis was made of a fibro-cystic tumour of uncertain origin, but there was a doubt as to its being due to pathological growth of foetal remnants. It was decided to remove as much as possible to ease the sitting.

Operation in July, 1894.—An incision four inches long on the inner border of gluteal fold and running up to left labium minus was made and carried through adventitious capsule of growth. This was found to consist of rounded dark masses very like the gizzard of a fowl in section. A good quantity of the growth was removed and in posterior part a small central looser reticular space was seen. A uterine sound passed into this was carried without any force parallel to the vagina in the ascending portion of the tumour up to the uterine level. (An incision was made half way up the vaginal wall through this and down to the uterine sound. A small drainage tube was left in this opening and the external incision was closed.)

Patient made a quick recovery and was much relieved at the time, especially in sitting down.

In December it was evident that the growth was progressing, one cannot say recurring, because it was not all removed. I could make out a mass on the left of the uterus which felt firm and regular, not tender. In fact, a broad ligament tumour. Having the view now that I was dealing with a growth from the canal of Gaertner, and that the upper end formed a distinct para-uterine tumour I determined to treat it as a fibro-myoma and endeavour to bring about its retrogression by removal of the tubes and ovaries.

Operation in December, 1894.—There was found to be a fluctuating rounded orange-sized tumour on the left of the uterus, and the appendages on this side were rudimentary. The ovary was small and so loosely attached that it almost came away while I was ligaturing this side and without any force.

She made an uneventful recovery, and was much relieved both as regards the short acute dysmenorrhœic

pain and the feeling of tension in the pelvis. The lower end of the growth, however, was not affected by the removal of the appendages and cessation of menstruation, so on October 8th, 1895, I performed a third operation.

Under anaesthesia one could feel that the para-uterine tumour was imperceptible to bimanual examination.

A long antero-posterior incision over the first incision, but more extensive, was made up to the middle of left vulvo-vaginal border, and then the labia and vaginal walls were cut through up to the left vaginal fornix. The growth was dissected out, and in doing this the internal pudic vein was torn, but was easily controlled. The ascending portion gradually tapered off and was distinctly softer and more friable than the lower part. It was followed up into the broad ligament and removed, no mass of firm tissue being felt to be left behind.

The patient has done well and can now sit easily and perform her marital functions, which were quite inhibited. Microscopically, the growth presented no special characters beyond those of ordinary fibrous tissue.

The part removed in the first operation and the appendages have unfortunately been lost, but I have here the growth as removed finally, and the tapering off of the ascending para-vaginal limit is well seen. I think that this case presents many interesting points—(1) as to its origin, (2) as to treatment, (3) as to the limitation of the effect of removal of the appendages.

Transactions of Societies.

BRITISH GYNÆCOLOGICAL SOCIETY. ANNUAL MEETING HELD JANUARY 9TH, 1896.

CLEMENT GODSON, M.D., President, in the Chair.

THE TREASURER (Dr. MANSELL-MOULLIN) having read his annual report, which was of a highly satisfactory character, the ballot for the election of officers for the ensuing year was announced. The list will be found in our "News" column.

Cordial votes of thanks were accorded to the Treasurer, the Editor of the Journal, the Librarian, Secretaries, and Auditors, all of whom were unanimously re-elected.

THE EXCLUSION OF HOMŒOPATHIC PRACTITIONERS.

The PRESIDENT moved the adoption of the following new by-laws recommended by the Council:—1. That it is undesirable that any member of the medical profession practising homœopathy should be proposed as a fellow of the Society.

Dr. G. H. BURFORD hoped this was intended merely as an academic expression of opinion, and not a matter of society policy. When the society was founded, invitations were sent to many men interested in gynaecology, inviting them to join; and no test of opinions was hinted at. To introduce such a test now would be, he thought, a putting back of the hands of the clock; it would be a reversal of the whole policy of the society. He would like to know what had occurred to warrant this proposal.

The PRESIDENT stated that the proposal had resulted from a letter received from the Editor of *The Lancet*, asking how many homœopaths there were in the society, and suggesting that it was undesirable that such should be admitted fellows.

Dr. CARFRAE moved as an amendment that this by-law be not adopted.

The amendment having been seconded, Dr. HEYWOOD SMITH said he did not champion the cause of homœopathy, but he thought it would be a mistake for a gynaecological society to adopt such a by-law. Surgical principles were the same whether practised by allopaths or homœopaths. If it were a pharmaceutical or clinical society, where medicinal treatment was a prominent subject of discussion, it might be different.

The amendment was put to the meeting and negatived, being supported by only 4 votes. The original motion was then put and carried.

ADVERTISING IN THE LAY PRESS.

2. That it is contrary to the ethics of the British Gynaecological Society that any of its Fellows should advertise their publications, or otherwise bring themselves before the notice of the public by advertising in any way through

the medium of the lay papers. The Council would look with disfavour also on announcements sent round to the medical profession generally. This was carried unanimously.

The PRESIDENT, after being re-elected for another year of office, delivered an address, a abstract of which will be found in another column. After which

Dr. ROUTH moved a vote of thanks to the President for his address, and congratulated him on his re-election; by his direct influence a larger number of Fellows had been elected than in any preceding year.

The vote was seconded by Dr. MACAN, and carried with acclamation.

SPECIMENS.

The following specimens were shown by Professor MAYO ROBSON, F.R.C.S., of Leeds:—

1. *Myoma removed by Hysterectomy. A Method of treating a Divided Ureter.*—The patient was *et.* 50. The tumour was a large one, weighing after removal 20 lbs. When slitting the peritoneum in front of the tumour he found that the left ureter passed round in front, and that he had removed 2 inches of it. He had three courses before him: to remove the kidney, to establish a fistula, or to produce anastomotic union of the cut ends. Having formerly considered what he should do in the event of such an accident, he lost no time, but made a small vertical slit in the lower piece, so as to open it funnel-wise, and passed the end of the upper portion into it, retaining it in position with a few fine sutures. This procedure caused no difficulty, and the patient made an uninterrupted recovery, without any blood in the urine, or any other urinary symptoms.

2. *Ectopic Gestation in Left Fallopian Tube.*—The primary rupture occurred at the sixth week, with formation of hæmatocoele. She was admitted a week later, the history being clearly that of extra-uterine gestation. The left broad ligament was distended. The fluid gradually absorbed, and the tube could then be felt. This began to get larger, and so, in the twelfth week, she was operated upon and the gravid tube removed. No foetus was discovered, but chorionic villi were found on microscopic examination. The patient had made a good recovery.

3. *Sarcomatous alteration of Myoma. Hysterectomy. Intra-peritoneal treatment of pedicle by a method not previously described.*—This was one of several cases in which he had removed large solid uterine tumours after the menopause. There was evidence that the upper part of the tumour was malignant, and he believed that this occurrence was not very uncommon at that time. The patient had had the tumour for several years; when she was 51 years old it started increasing rather quickly. He performed hysterectomy, by a method he had used in several cases, viz, amputating above the cervix, and forming anterior and posterior flaps. In this case there seemed to be some oozing from one of the flaps; he therefore brought the uterus up and fastened the peritoneum round it, making the uterine wound actually extra-peritoneal; he then closed the fascia and skin over it entirely. Recovery was rapid.

4. *Fibro-Cystic tumour removed from between the layers of the sigmoid meso colon.*—The patient was *et.* 43. The tumour had been growing rapidly. On opening the abdomen, the uterus and ovaries were all separate from the tumour. Passing over the top of the latter was a coil of large bowel which seemed to be transverse colon. It looked as if it could not be got away; however, he incised the peritoneum over it, and it then shelled out fairly easily from between what turned out to be the layers of the sigmoid meso-colon. He feared gangrene of the bowel, but no accidents occurred and the patient made a satisfactory recovery.

5. *Myoma Uteri filling Pelvis in 8th month of pregnancy. Removal per vaginam without interference with pregnancy.*—When seen, at the 8th month of pregnancy, the patient had a myoma involving the lower part of the uterus, and filling the pelvis. It was not polypoid. In a similar case he had done a Porro's ovariectomy. In this case he slit through the capsule of the tumour, which was on the posterior lip of the cervix, and shelled out one after another, a number of small fibro-myomata. The patient did not miscarry, but went on to term and had a normal confinement.

6. *Myoma Uteri removed by the Vagina.*—Owing to profuse hæmorrhage, the patient was very blanched. The cervix was expanded and the os could only be felt as a slit high in the vagina behind the pubes. The tumour filled the vagina and reached to the umbilicus. It was enucleated through the vagina, after incising the posterior lip of the cervix. There were no bad symptoms, and patient made a good recovery. When the patient left for home, at the end of the month, no remnant of the tumour could be felt.

The PRESIDENT thanked Professor Mayo Robson in the name of the Society for his interesting specimens, and congratulated him on his brilliant results. He thought that his treatment of the ureter would be of the greatest advantage to any surgeon who should meet with a similar accident.

Mr. BOWREMAN JESSETT thought the first specimen was of special interest; the method adopted for repairing the ureter was novel, simple, and ingenious; it was an accident that might happen at any time, and if it occurred to him he would use Professor Mayo Robson's method. As regards the second case, he thought that total removal of the uterus was better, because it was simpler, and drainage could be secured more efficaciously. But both pan-hysterectomy and Professor Mayo Robson's plan were better than the use of the *serre-naud*, and he was one of those who hoped to see this instrument relegated to the museums of antiquities. He agreed with Professor Mayo Robson that fibroids not uncommonly took on malignant characters after the menopause.

Dr. HEYWOOD SMITH said he was not yet satisfied as to whether pan-hysterectomy or partial hysterectomy were the better treatment for fibroids. It would form a good subject for discussion during the coming year. At present the mortality of pan-hysterectomy seemed to be the greater.

Dr. LEITH NAPIER congratulated Professor Mayo Robson on his excellent results. The first case was a very teaching one; he was not prepared to say whether the means adopted for the ureter were unique, but it was better than any other method hitherto recommended. It was questionable, however, if it would be available if the accident were not discovered at the time, or if a large piece of ureter had been removed. In a case lately reported by Roth, of Berlin, he found it necessary to pass a catheter into the ureter, but if this had to be done every time a ureter was injured it would greatly add to the difficulties of abdominal surgeons. As regards the increase in the growth of fibroids after the menopause, he had, during the last four or five years, seen fourteen cases where this had happened. Probably some of these cases which became sarcomatous might be regarded as originating as soft glandular adenoid tumours. The hard fibroids generally atrophied.

Professor MAYO ROBSON, in reply, said it only remained for him to thank the Society for the cordial reception they had given to his contributions. He had read with great interest Mr. Bowreman Jessett's paper on Pan-hysterectomy; he believed that Mr. Jessett's procedure brought the operation under the category of practical surgery; he did not, however, think it would do for all cases.

Mr. FRED. EDGE, of Wolverhampton, showed a specimen of

PARA-UTERINE AND PARA-VAGINAL TUMOUR EXTENDING INTO THE LEFT BUTTOCK,

the note of which will be found under the heading of "Clinical Records."

EDINBURGH MEDICO-CHIRURGICAL SOCIETY. MEETING HELD WEDNESDAY, JANUARY 15TH.

The President, Dr. ARGYLL ROBERTSON, in the Chair.

Dr. CAIRD showed a boy in whom he had performed supra-pubic cystotomy for rupture of the urethra with no extravasation of urine. In order to find the urethra he had to pass an instrument from above and cut down upon it.

SPECIMENS.

Dr. W. ELDER showed—1. A brain from a case of aphasia of 17 years' duration. The patient, a female, had a shock of paralysis 14 days after childbirth with right

sided hemiplegia. On two different occasions afterwards she was treated in an asylum for mental symptoms, and shortly before death she had what appeared to have been a congestive attack. During her illness she was able to speak, but could not use the proper words; her hearing for sounds was perfect, for words very defective; she could not write nor add up sums, although she seemed to be able to check mistakes in bills. The brain was normal, save for atrophy of the left temporo sphenoidal lobe; the supra-marginal gyrus was affected, accounting for the visual defect. 2. Hypertrophied bladder wall with dilated ureter following stricture of the urethra.

Dr. F. BOYD showed an aneurysm of the aorta, with rupture into the lung. There were no previous symptoms in the case before the rupture took place, and the pleura on one side was found adherent also without any previous history of disease.

Dr. D. GREIG showed a "Cathartine" cast of lupus vertuosus.

Dr. NOEL PATON read a paper on

THE ACTION OF THE LIVER ON FATS.

Dr. Paton commenced by reviewing our present knowledge from previous work on this subject. He pointed out that it was generally held that the liver caught the sugars and proteids of the food, while the fats were thrown directly into the venous circulation by means of the lymphatic duct. Nasse thought that the liver was directly connected with the metabolism of fats, but used erroneous data in his observations. Langley, from a microscopic examination of the livers of frogs, thought that the liver must have to do with fats. With regard to methods, the old way of estimating the amount of fat in the liver by means of extracting with ether was fallacious, as the amount of fatty acids in the liver was very great. The fatty acids must be separated from the ether extract. In the liver the solid fatty acids, palmitic and stearic, predominated. The change in the percentage of fats in the liver might be due to accumulation of fats or to increase in decomposition. Remembering, however, that change in the other constituents of the liver might alter the percentage of the fats, he had investigated the effect of starvation on the fats of the liver in cats, kittens and pigeons, and found that after four days the average of fat remained practically the same. Could this be because the liver acted as a storehouse of phosphorus? In order to settle the question of storage, kittens were fed on cream. The melting point of cream fat is lower than that of the liver, and it was found that the fat stored in the liver did present a lower melting point sixty to seventy hours after the melting point of the stored cream fat rose. Fats were, therefore, stored in the liver in some animals. In the salmon it was stored in the muscles, in the pig in the adipose tissue, and in the cod, sheep, rabbit and cat in the liver. If there was a relation between the ingestion of carbohydrates and the formation of fats, as there undoubtedly was, we should get an increase of fats in the liver when the glycogen was disappearing from it. He found that this was the case in rabbits fed on a carbohydrate diet and then starved. It had been suggested that the body fats took the place of those in the liver under those circumstances as occurred in phloridzin poisoning. In the latter case the blood became milky, but did not do so in starvation. Probably glycogen can, therefore, be transformed into fats as well as into sugar in the liver. Pflüger's researches showed that there was no evidence to support the theory that proteids were a source of fats. A proteid diet increased the metabolism in the liver, and fats, if formed in greater quantity, might be broken down faster. Evidence of this might be found in the results of feeding with proteids, and, therefore, it might possibly be true that fats were formed from these bodies.

Dr. G. A. GIBSON asked why in phosphorus poisoning the liver decreased in size if the fats were kept at the normal? and suggested that Ebstein and his school were wrong, if Dr. Paton was right, in treating obesity with fatty food.

Dr. DUNLOP said that Dr. Paton had proved that lecithin was present in the liver in much greater quantities than former observers, and stated that at his suggestion he had investigated the fats in the liver in fatty infiltration and degeneration of that organ. He could find no difference between the fats present in the two.

Dr. LOCKHART GILLESPIE asked if the phosphates in the urine during starvation had been estimated, as, if there was no phosphorus ingested and some being eliminated, he failed to see how the phosphorus in the liver could remain constant without grave changes throughout the body. He also asked if Dr. Paton believed with Pavy that fats were formed in the cells of the wall of the intestine, and if so what effect that would have on his theory of the liver storage of fat.

Drs. GULLAND and STOCKMAN also spoke.

Dr. PATON, in reply, thought that in phosphorus poisoning the liver substance became disintegrated from the action of the poison. He did not believe that fat was formed in the intestinal cells, that in starvation phosphates were excreted in the urine in very small amount, and that the storage of them in the liver did not undergo a relative decrease.

Dr. LEWIS read a paper entitled, "An Inquiry into the Physiology of the Action of the Thermal Saline Baths and Resistance Exercises in Chronic Heart Disease (the Bad Naubeim and Schott System)." The principal point he brought out was that the marvellous reports of decrease in the cardiac dulness were not to be implicitly trusted.

Drs. GIBSON and BALFOUR discussed the paper.

THE HUNTERIAN SOCIETY.

MEETING HELD WEDNESDAY, JANUARY, 8TH (at the London Institution).

The President, MR. CHARLES J. SYMONDS, F.R.C.S., in the Chair.

AFTER the election of an unusually large number of new members, Dr. JAS. H. SEQUEIRA read a paper entitled:—

CHRONIC PHARYNGEAL AFFECTIONS AND THEIR RELATION TO DIPHTHERIA.

Admitting diphtheria to be a specific bacillary disease, he wished to consider the entrance of the bacillus by the air passages: he referred to the fact established by Drs. Thompson and Howlett that air filtered through the nares was practically germ free, and hence deduced as a corollary that anything which contributed to oral breathing must be a predisposing factor in the onset of diphtheria. He then drew attention to the depth of the crypts of the tonsils where bacilli could rest undisturbed, and to the altered vitality of the tonsillar mucous-membrane in catarrh. From these two premises he then proceeded to draw conclusions and summed them up as follows:—
1. Tonsillar hypertrophy and post-nasal adenoids are found chiefly in children from the age of two to puberty, and 80 per cent. of the cases of diphtheria are found between those ages. 2. These pharyngeal affections are rare after 30, while only 3 per cent. of diphtheria cases occur at this period of life. 3. 72.5 per cent. out of 40 cases of diphtheria that he had examined presented evidence of tonsillar hypertrophy. 4. Diphtheria is a common sequela of scarlet fever, which severely affects the tonsils and often leads to mouth breathing.

Dr. FRED J. SMITH said he thought that adenoids and enlarged tonsils with catarrhal conditions did not account for the whole increase in vulnerability to diphtheria, something more must be added in the shape of general constitutional weakness of resistance to infection.

Dr. HINGSTON FOX laid stress upon family disposition to the incidence of specific diseases, and said he knew of many cases in which immunity seemed to run in families.

Dr. A. DAVIES referred to his experience of the frequency of diphtheria as a sequel of scarlatina.

Dr. F. WARNER quoted a case of simple tonsillitis (occurring in the nurse of a diphtheria patient) in which no diphtheria bacilli were found.

Dr. GOODALL was not at all convinced that throat diseases did predispose to diphtheria. He referred to the difficulty of obtaining reliable histories of the previous condition of the throats of the patients in the fever hospitals, and he suspected that it might prove that diphtheria was the cause and not the consequence of chronic throat trouble. He recognised diphtheria as a sequel of scarlet fever, but said it occurred very irregularly, now attacking very few and then a large proportion of convalescent scarlatina patients.

The PRESIDENT mentioned two cases of removal of adenoids which had unfortunately succumbed to diphtheria after operation for removal of the growths.

Dr. SEQUFIRA briefly replied.

Dr. FORTESQUE FOX then read a paper entitled,

LOCALISED RHEUMATOID ARTHRITIS.

Simple local arthritis, he considered, was distinguished from all other forms of degenerative joint lesion, specific, septic or nervous. Whilst the latter are parts of generalised disease, simple arthritis was a local disease, excited by injury, in those in whom from hereditary causes or senility the joints were vulnerable. Hence it affected by preference exposed joints, and the right side of the body. A summary was given of thirty-nine cases of local arthritis met with at Strathpeffer Spa, and affecting the shoulder, knee or hand. In the hand the basal joint of the thumb was most commonly involved, "typical senile local arthritis" causing a cupping of the palm. "Last joint arthritis" was regarded as a form of gout in women. "Residual arthritis," the result of bygone acute rheumatism, &c., was also distinguished from proper local arthritis. The latter belongs to the climacteric and the senile periods. The treatment consists in active irritation in the early stages, rest, and later some form of thermal treatment. The methods in use at Strathpeffer were described. The prognosis in most cases is not unfavourable.

HARVEIAN SOCIETY OF LONDON.

THE ANNUAL MEETING AND CONVERSAZIONE HELD ON THURSDAY, JAN. 16TH.

The President, SIR JOHN WILLIAMS, Bart., in the Chair.

The Annual Reports of the Council and Treasurer were read and unanimously received by the Society.

PRESIDENTIAL ADDRESS.

The PRESIDENT then delivered his Annual Address, in the course of which he dealt with the changes that had occurred in the various Examining Bodies with regard to their examinations in Midwifery, showing how some thirty years ago this subject received but scant attention at their hands. He pointed out how important it was that those who presented themselves for examination in midwifery should be able to satisfy the examiners as to their knowledge of the shape and diameter of the female pelvis, the anatomy of the pelvic organs and the size of the fœtus at various times during gestation, and particularly at term. He said that upon these data rested the science and art of midwifery, and they were the first essentials of that science. Sir John Williams went on to describe the changes which had taken place during the last forty years in various operations, and showed how the recognition of the relative sizes of the pelvis and of the fœtus had influenced the manner in which these operations should be performed, and the period at which they should be undertaken. He concluded with a criticism of the term "Meddlesome Midwifery," and showed how proper interference undertaken at the proper time, during gestation or labour, might be justifiable and even imperative so long as its aims were the saving of the life of the mother and child. The officers for the ensuing year were then balloted for and elected. The list will be found in our "News" column.

Cordial votes of thanks were accorded to the President, Treasurer, the retiring members of Council, and to Mr. Peyton Beale, the indefatigable Honorary Secretary.

These formalities were followed by a *conversazione*, which, we understand, was a success, but, as the usual courtesy was not extended to the medical press, we are unable personally to vouch for.

FRANCE.

[FROM OUR OWN CORRESPONDENT.]

PARIS, Jan. 18, 1896.

ARTIFICIAL SERUM.

At the meeting of the Société de Chirurgie, M. P. Michaux gave his experience on the treatment of post-

operative peritoneal septicæmia by intravenous injections of artificial serum. For the last three years he has used these injections twenty-five times after major operations, and more or less frequently for shock or abundant hæmorrhage, and in these later cases with marvellous results, regular resurrections were operated before his eyes. Of the twenty-five cases he had kept a detailed account of fifteen, which he submitted to the meeting. In all the cases the septic symptoms were very grave; distension of the abdomen, pulse quick and wiry, temperature low, or scarcely above the normal, gripped face, eyes sunken, nose pinched, &c. Five of the fifteen cases recovered, and amongst them the most interesting was that of a woman of fifty, on whom he had performed six weeks ago vaginal hysterectomy for an enormous fibroma. The operation lasted an hour and a half. The evening of the second day the general condition was not satisfactory, and the following morning, in spite of the antiseptic dressing unmistakable signs of peritoneal septicæmia had set in. Seeing that there was no time to lose, M. Michaux removed the instruments from the vagina, applied ice to the abdomen and injected into the cephalic vein a quart of artificial serum. The temperature, which had been under the normal, rose hourly up to 103° and then gradually went down, so that on the following day it stood at 98° or thereabouts. Injections of the serum were also made five or six times in the cellular tissue. After five or six days of this active treatment matters took a good turn, and at the time of speaking, the patient was out of danger. In another woman, æt. 33, who had undergone a similar operation for pyosalpinx, septicæmia set in on the third day. After injecting into the veins of the arm over a quart of serum the speaker re-opened the abdomen and by means of a large drain in the vagina, washed out the cavity with warm salted water. Two days afterwards a marked improvement took place; the washings of salt water were continued for eight days and the patient recovered completely.

In two other cases the patients were literally dragged from the jaws of death. Where death does ensue, M. Michaux remarked that the injections of artificial serum retarded for four or five days at least the fatal *dénouement*. Nearly all the injections were made with the serum of Hayem, but more than once he contented himself with boiled water, and from two to three drachms of sea salt. The liquid is filtered through hydrophile cotton and boiled for fifteen minutes in a bottle and then hermetically sealed until ready for use. The operation, as practised by M. Michaux, is simple enough. After cleaning, antiseptically, the region, he incises the teguments directly over the cephalic or basilic vein, which, when properly exposed, he opens by a V-shaped incision, and introduces the canula of the syringe, taking care that no bubble of air is injected. The liquid, heated to 103°, is slowly injected. The effect on the patient is immediate; the respiration becomes deeper and more expansive, the pulse becomes full and diminishes in frequency, and a general *bien être* is experienced. Sometimes a certain amount of dyspnoea is observed and vomiting, but only after large doses. The quantity of urine is greatly increased by the transfusion when repeated for a few days. Besides the intra-venous injections, M. Michaux said he was in the habit of injecting into the subcutaneous tissue small quantities of the serum with good effect, and even exclusively in the least grave cases.

Although he was confident that intra-venous injections

of artificial serum constituted a precious resource in the treatment of peritoneal septicæmia, he was far from being indifferent to the important services rendered by the other means usually employed against this grave complication, in the front rank of which should be placed purgatives and enemata, applications of ice to the abdomen, and a large abdomino-vaginal drainage.

CARDIAC LIVER.

UNDER the above title Prof. Lépine, of Lyons, has just published an article on the treatment of hepatic affections as a sequence to certain forms of heart disease. It is well known, says the writer, that the liver in its normal condition is a very soft organ, and distends like a sponge under the influence of the sanguine flux. Consequently, when for any reason the tension increases in the right auriculum, the liver increases rapidly in volume, provided, however, that no cirrhosis exists which, by the development of the conjunctival tissue, deprives the organ of its softness and elasticity.

The edge, which is scarcely visible in the normal state can be felt far below the false ribs, hard and resisting. If, on the other hand, the tension in the right auriculum disappears, almost immediately the liver disgorges itself and returns to its primitive volume. This great permeability and softness of the liver explains sufficiently the facility with which can be observed the hepatic pulsations described by Prof. Potain, and met with in each case of insufficiency of the tricuspid valves. It follows naturally that the treatment of cardiac liver should consist in diminishing as much as possible the tension existing in the auriculum and the inferior vena cava.

I had recently, relates M. Lépine, in my wards, simultaneously three patients suffering from insufficiency of the tricuspid valves, and presenting, each of them, an enormous liver, the lower edge reaching as far down as the umbilicus. In one of them the affection was of recent date. Under the influence of digitaline the dilatation of the right heart diminished considerably, but the lower edge of the liver remained in the same position, at which I was much surprised. In seeking the cause of this anomaly, I found that all the patients ate well, and especially a good deal of meat. I put them immediately on a milk diet, and soon I had the satisfaction of seeing the liver recede almost completely under the false ribs. After all, the fact was not very extraordinary, as digestion and above all that of meat, produces a notable congestion of the liver, as may be proved by opening the abdomen of a dog after a heavy meal; the portal vein will be found to be enormously distended and the mesenteric arteries to beat with violence and the liver considerably distended. The natural inference to be drawn from this physiological fact is the necessity of excluding meat from the diet of patients suffering from tricuspid disease.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, JAN. 17th.

THE TITLE OF PROFESSOR.

THE title of Professor, until a few years ago, was never conferred on medical men having no teaching connection with a university. The highest rank men who were not teachers could then attain to was that of Geheimer Sanitätärath or Privy Sanitary Councillor or in the case of medical officials, Geheimer Medizinalrath, or Privy Medical

Councillor. The first occasion, therefore, on which the title was bestowed naturally gave rise to a good deal of talk on the part of members of the profession. The clinician Dr. Paul Ehrlich was the first to receive the titular distinction, and it was bestowed on him in consequence of his studies into the colour-analysis of blood. He was then an assistant in the Frerich Klinik. Since that time a number of non-teaching practitioners have been the recipients of the distinction. Reuvers, then assistant in Leyden's Klinik, and now Director of the Moabit Hospital, was among the earlier ones thus distinguished. Albert Köhler, assistant in Bardeleben's Klinik, soon followed, then Emil Behring, the so-called founder of blood-serum therapeutics, and now ordinary in Marburg. Then came staff-surgeon E. Pfuhl, for many years assistant to Robert Koch, and now organiser of the bacteriological laboratories in connection with the army sanitary officials. Dr. George Cornet, known for his investigation into the spread and prophylaxis of tuberculosis, and Dr. Kitasato, of Japan, both for several years volunteers in the Koch Institute, then followed. These were followed by a number of others, mostly men of distinction and connected as directors with public institutions. Amongst them may be mentioned Eugen Hahn, of the City Hospital, Friedrichshain; Langenbuch, of the Lazarus Hospital; James Israel, of the Jewish Hospital; Wagner, of Königshütte, and a number of distinguished provincial medical men. Finally, the title has been bestowed on Dr. Baume, a dentist and a member of the Dental Examination Board of this city. The conditions of the bestowal of the title are now so far changed that the Cultus Minister grants this or that of Sanitätärath as seems the most suitable for any given case.

At the Berlin Medical Society, Hr. Saul read a note on the

STERILISATION OF CATGUT.

After numerous experiments he came to the conclusion that this was best effected by storing it in a solution containing eighty-five parts of alcohol, five parts of carbolic acid, and ten of water. In this solution the spores of anthrax were killed in ten minutes. He showed an apparatus for the purpose made under his direction by the firm of Gebrüder Lautenschläger.

Herr O. Israel then showed two preparations of

DIFFERENT FORMS OF CANCER FROM ONE INDIVIDUAL.

The patient, a man, set. 50, was admitted into hospital, suffering from cholelithiasis. The gall bladder was sutured and fifteen stones removed from it. The patient was also suffering from mitral stenosis, and died soon after from his cardiac trouble. The autopsy and microscopical examination showed that the anterior wall of the gall bladder was the seat of a cylindrical-celled carcinoma, and that a canceroid sprang from the head of the pancreas and projected into the duodenum. He said that the form of growth in the pancreas was a great rarity, but the presence of two cancerous growths of different kinds in one individual was a very great rarity. He saw such a case, however, in 1883, in a man, set. 69, who had canceroid of the tongue and cylinder-celled carcinoma of the jejunum.

At the Hufeland Society Hr. Liebreich showed a patient in illustration of the

STIMULATING ACTION OF CANTHARIDINE.

The man, who had suffered from syphilis, was not improved in any way by a course of mercurial treatment. It was only after taking cantharidine that the mercury had

any effect. The symptoms of syphilis had then mostly disappeared. In a similar case the speaker had also tried cantharidine with a good result.

Hr. Saalfeld said that he had also treated a number of cases with mercury and cantharides simultaneously, some of them being individuals with distinct evidences of tuberculosis. In these cases it was known that one had to be very cautious with mercury. Some were cases that had not improved either under mercury alone or under mercury and potass iodide combined. In the case of the phthical patients, mercury could be given in the usual quantities when the cantharidine was given at the same time. In the second group of cases with torpid ulcers and no tendency to heal, improvement set in with increased flow of serum after cantharidine had been given.

The same speaker then showed a patient with a

SYPHILITIC GUMMA OF THE FOREHEAD.

The diseased parts had a certain resemblance to lupus gummosus. On application of the phaneroSCOPE, however, and glass pressure the diagnosis was very clear; there was then no trace of lupus vulgaris.

Hr. Hausemann then spoke on

AN UNUSUAL CASE OF MORBUS ADDISONII.

He said that the significance of the supra-renal capsules in Addison's disease was not yet sufficiently recognised. Some inquirers looked upon the supra-renal affection as secondary, and thought the primary disease lay in the solar plexus, the splanchnic nerves, and the spinal cord. There was no doubt the capsules might be completely destroyed without the onset of Addison's disease, as in the case of a woman, *æt.* 53, both of whose supra-renal capsules were completely destroyed by cancer metastases without a trace of Addison's disease appearing. The same thing occurred as regarded the pancreas and diabetes. All disease of the pancreas might lead accidentally to diabetes, but there was a diabetes independent of the pancreas. Granular atrophy of the pancreas led on to diabetes with great regularity.

The case he brought forward was that of a man of 30, of healthy parentage and always healthy himself. He was admitted into hospital in June last suffering from impaired nutrition, slight jaundice, great weakness, that was increased by vomiting and deficient ingestion of food. The lungs, heart, spleen, and kidneys were sound. Pigmentation was well-marked, especially in cicatrices and on the edges of the *velum palati*. He died in 14 days. The autopsy showed brown atrophy of the heart, in the lungs small cicatrices with small caseous patches, swelling of the follicles of the intestines, patchy swelling and redness of the mucous membrane, and some hæmorrhages. All the organs except the supra-renal capsules were unchanged. These were united to the adjoining parts by fibrous bands. As flat surfaces they were of fair size, but they were very thin. Every trace of yellow cortical substance had disappeared. In some foveæ a round-celled infiltration was present. There were no neoplasms. There was no positive change in the nervous apparatus, except a few pigmented ganglion cells in the solar plexus. There were no changes in the cord. The absence of the cortical substance of the supra-renal capsules must, therefore, be the sole cause of the disease.

EIGHTEEN fatal accidents occurred in the Alps last summer, 4 in the French Alps, 6 in the Swiss, 6 in the German and Austrian, and 2 in the Italian Alps.

[FROM OUR OWN CORRESPONDENT.]

Vienna, Jan. 17th, 1896.

LEPROSY.

PROF. KAPOSI opened his Clinic by showing a few cases of leprosy that have lately come under his notice. In recounting the early history of the disease, which he admitted was of great antiquity, he assured his audience that we were indebted to the Arabian medical schools for the most of our knowledge concerning its ancient history. In the Latin translation of these works the Arabian term "Dal fil," which, correctly rendered, is "an elephant's foot," has been translated "Elephantiasis," or "elephantopus," but more recent investigations have classed it as a thickening of the skin, or pachydermia, or "Elephantiasis Arabum." In the original Arabian works of medicine we meet with another term "Djudzan" which appears to have included a number of diseases with nodules on the surface of the body, associated with shedding of the nails, and subsequently proceeding to a fatal termination. These could be more correctly translated as leprosy. It was not until the Renaissance period that these works, whose contents have thrown much light on the disease, were discovered in the cloisters. In the Greek language there is another disease described under leprosy corresponding to the Arabic term, but from closer inquiry it appears that the disease has no grave consequences, only attacking the skin and leaving large white patches, which we are inclined to believe was *peoriasis*; indeed, the late Sir Erasmus Wilson, termed it "crescentic lepra *peoriasis*." The Arabians appear to have had another allied disease which they called "Albaras" represented in the Greek by "Morphosa," which was either "Albos" or "Melas" or black and white, agreeing in some measure to our "Vitelligo."

The constitutional disease or general lepra appears to have reached extraordinary dimensions in Europe between the 10th and 12th centuries when hospitals were everywhere provided for their isolation. At that time the leper was under the necessity of carrying a bell to give notice of his presence, so that the healthy might pass without coming in contact with the diseased person. The word "Zarad" in the Bible is translated by the "Septuaginta" as Leger, but this included other diseases. After this time the epidemic seems to have gradually disappeared, when syphilis made its appearance, which was for some time considered as another form of leprosy. It has now disappeared, except in limited localities, such as Norway, Sweden, Finland, South of Spain, Constantinople, and South America. Leprosy may be correctly divided into "Tuberoea," "Maculoea," and "Anæsthetica." The "Tuberoea" form appears like large papular syphillides over the hands, feet, and various parts of the body, ultimately passing on to ulceration. The "Maculoea" appears as bronzed or brown spots on the surface, which soon become anæsthetic and atrophied. The third, or "Anæsthetic," often begins with a "Maculoea" appearance, subsequently forming vesicles and terminating in complete anæsthesia. The neurilemma of the fibrille first becomes infiltrated and thickened till the tactile sensation is quite lost as well as that of heat and cold. There is one peculiarity that still remains to distinguish this disease and that is the muscular sensation of the feet is retained as the patient is able to stand quite steady when the eyes are closed.

MEDICAL FACULTY FOR LINZ.

The inhabitants of Lower Austria have petitioned the Austrian Government for a new medical school at Linz. They complain of the wide area in their province which is without medical aid, and assure the Government that a better provision could be made if a centre of education were established in their midst. Another complaint is the defective arrangements of the Government for carrying out sanitary reforms which they think would be better accomplished by a Faculty of their own.

PROF. ALBERT has again returned to his clinic after a severe illness from gout. Prof. Hochenegg has been performing the duties of lecturer, and will continue throughout the session to do so.

The Operating Theatres.

MIDDLESEX HOSPITAL.

STEPHEN SMITH'S AMPUTATION AT THE KNEE-JOINT FOR GANGRENE OF THE LEG AND THROMBOSIS OF THE FEMORAL ARTERY.—MR. PEARCE GOULD operated on a man, *æt.* 57, but looking considerably older. Occupying the middle third of the outer surface of the patient's right leg was an ulcer more than six inches long, extending down to the interosseous membrane, to the tibia and to the fibula; this was caused by gangrenous inflammation; the slough had nearly all separated, but the exposed outer surface of the tibia was necrosed. The foot was very oedematous. Pulsation was felt in the femoral artery down to the apex of Scarpa's triangle, below which no arterial pulsation could be detected. The leg was removed at the knee-joint below the semi-lunar fibro-cartilages, the stump being covered in by lateral flaps taken from the leg according to the method of Stephen Smith. The femoral artery was found filled with a dark red thrombus; the arterial wall was not notably thickened or otherwise diseased. Mr. Gould said it was necessary in these days for a surgeon to justify very completely every amputation, but he believed that in this case there was no other course open to him to pursue. The existence of the thrombosis, together with the feeble state of the patient, rendered it probable that the ulceration would never heal, but, even were healing to be obtained, the man would be left with a useless and troublesome leg. The extensor and peronei muscles were destroyed, so that the foot would be in a condition of paralytic equino-varus; and the anterior tibial and musculo-cutaneous nerves having also been destroyed, the dorsum of the foot would be deprived of all sensation, and would probably become quickly the seat of trophic sores. Having decided to amputate, the question arose as to the best method to adopt: he had chosen Stephen Smith's amputation through the knee-joint because it was attended with less shock and less hæmorrhage than any amputation through the lower part of the thigh; if successful it would leave the man a better stump than an amputation higher up. In the patient's feeble state Mr. Gould attached great importance to the little shock and trifling hæmorrhage (in this case not amounting to half-an-ounce), and this was the chief reason that had weighed with him in his decision. He was aware, however, that this operation was in this particular patient attended with risk; the flaps of skin and fascia which he had reflected from the leg were very thin, and at the same time were of necessity long, and with thrombosis of the popliteal and

femoral arteries there was danger that one or both these flaps would slough. He pointed out that the outer flap, owing to its less free blood supply, was more liable to slough than the inner flap. In speaking of the thrombosis, he drew attention to the probability of its being due to an extension of clot from the anterior tibial artery, the seat of disease, and not to extensive disease of the arterial wall, the case differing wholly from another he mentioned, in which he had recently performed the same operation for gangrene of the leg due to obliterative arteritis, and in which the popliteal artery was found to be filled, not with a thrombus, but with organised fibro-cellular tissue.

KING'S COLLEGE HOSPITAL.

SECONDARY NERVE SUTURE AFTER DIVISION OF THE ULNAR NERVE.—MR. CARLESS operated on a young woman, *æt.* about 20, who sustained a glass wound of the wrist: four months previously, severing the ulnar nerve. An attempt had been at once made by the medical attendant to suture the divided ends, but the result was unsatisfactory, as also were two subsequent operations performed by the same medical man. On admission the usual signs of division of the ulnar nerve at the wrist were markedly evident, namely, complete anæsthesia of the little finger and adjacent side of the ring finger, flexion of the fingers, especially sustained, flexion particularly of the little and ring fingers, inability to adduct and abduct the fingers, and defective mobility of the thumb. The muscles were exceedingly wasted, and the electrical reaction very imperfect. After exsanguinating the limb by Lister's method of elevation the nerve was exposed by an incision extending along the radial side of the flexor carpi ulnaris and pisiform bone; there was a large amount of cicatricial deposit in the neighbourhood of the injury, but the ends of the nerve were readily found above and below this. The mass of cicatricial tissue constituting the bulb was freely dissected away and the nerve ends divided transversely so as to expose the nervous fibrillæ. It was then found that although over three-quarters of an inch of tissue had been removed the divided ends could be brought into apposition with scarcely any tension. One deep stitch was passed through the whole substance of the nerve at about a centimetre distance from the divided ends. This, when tied, acted as a traction stitch to diminish tension upon the ends when united. Four fine sutures were next inserted so as to secure accurate apposition of the incised extremities, which were brought into accurate apposition by this means. The wound was now closed and dressed in the usual way, and a plaster-of-Paris splint was put on the dorsal aspect of the forearm and hand so as to keep the latter well flexed. Mr. Carless commented on the necessity of free and complete removal of the whole mass of cicatricial tissue which intervened between the nerve ends in these old-standing cases; it is absolutely essential, he said, that the actual nerve fibrillæ free from infiltration should be brought into contact. In many cases it is impossible to accomplish this owing to there being insufficient tissue, and when such a condition exists the ultimate prognosis is very unsatisfactory, whatever precautions are taken to make up for the defect. In this case fortunately the ends were easily brought into contact and the prognosis was consequently increasingly hopeful.

It is satisfactory to state that by the eighth day sensation had been almost entirely regained in the anæsthetic area, that the fingers were not quite so much flexed, and that the movement of opposition of the thumb to each of the finger tips could be accomplished.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, JANUARY 22, 1896.

THE INSANITIES OF PREGNANCY AND THE PUERPERIUM.

THE subject of the insanities of pregnancy and the puerperium ranks, in the matter of obscurity, with that of puerperal fevers, but while the latter have profited by the greater knowledge at present possessed in respect of the influence of pathogenic organisms in their causation, the insanities have remained in the chaotic condition in which they were bequeathed to us by our professional ancestors. Before attempting a classification it behoves us to decide whether or not there are really forms of insanity peculiar to the pregnant or the puerperal states. We are fully aware of the fact that women are more prone to mental disturbances at particular epochs of their life's history, but this alone does not establish any special relationship. Certain persons inherit or acquire a liability to mental disturbance under comparatively slight stress, and it is presumably only in such persons that any form of insanity can declare itself either during the puerperal period or at other times. It would not seem that these attacks present any features which enable us to differentiate them from cases of insanity due to other causes and if the puerperium acts only as a determining factor in virtue of the great demands which maternity imposes on the female

organism it follows that we have to do only with this or that variety of ordinary insanity, although in the cases under discussion the attack may have been precipitated by the physiological strain of conception and delivery. There is, however, good reason for believing that a large number of cases of puerperal insanity are the direct and immediate result of septic infection, and, as might be expected, these cases are at present far less frequently met with than in the old days of midwifery before the introduction of antiseptic methods. These are the cases, if any, which really merit the designation of puerperal insanity. But even if all cases could reasonably be referred to this source, which is certainly not true, insanity thus induced does not differ essentially from the forms which are constantly met with as the result of toxic influences generally. Indeed, the pathological appearances would appear to be virtually indistinguishable from those due to phosphorus poisoning, for instance. They ought, therefore, strictly speaking, to be classed as toxic insanities, and not as puerperal insanities. All classifications hitherto proposed, including that brought forward by Dr. Savage, at the last meeting of the Medical Society of London, are ostentatiously unscientific. Some varieties are classified in accordance with their supposed etiology, others again, according to the period at which they occur, and lastly, by way of a *reductio ad absurdum*, by their duration. Such a classification sins against all the canons of scientific consistency, and if this be really the best that specialists can offer us, it only emphasises the fact that we have still much to learn in this department before we can get a clear view of the nature and relationship of the various forms of mental disease which occur in connection with pregnancy and labour. The most salient feature of all these forms of insanity, so-called puerperal, is their curability. This is something to be thankful for, seeing that, according to most statistics, one out of every forty cases of insanity occurring in females is due to this cause. The proportion of recoveries is given at 80 per cent., and these figures only deal with cases, presumably the more severe, which have been treated in asylums. A complete return, including the more manageable cases which are successfully treated at home, would certainly give a much larger proportion of recoveries. One curious fact was brought out in the discussion which followed on Dr. Savage's paper, viz., that illegitimacy is far from having the influence usually attributed to it. Theoretically, the mental distress which is entailed by an illegitimate pregnancy ought to result in the overthrow of all unstable minds, but the figures show that, as a matter of fact, girl-mothers contribute but an infinitesimal proportion of the cases of so-called puerperal insanity. The explanation is probably that women who “fall” in this way are persons with strong animal passions and a physique to correspond. Moreover, they belong for the most part to the uneducated classes and feel less acutely than might be imagined the irksomeness of their position in society. It is an open question how far treatment may be relied upon to avert or attenuate an attack. In view of the fact that such attacks are almost invariably

ushered in by a period of sleeplessness and watchful anguish, there is a great temptation to seek to remedy this symptom by the administration of narcotics. Those who have had most experience of such cases are confident that an attack may sometimes be averted by such treatment, and it is impossible to challenge the accuracy of their statements. Whatever the effect may be in the stage of incipency it is plain that little is to be gained by the use of sedatives in large doses once the attack is fully developed. Each physician has his favourite panacea, one gives chloral and bromides, another Indian hemp, and another alcohol, in full doses, the last named being of questionable wisdom, unless the precaution be taken to render the drug sufficiently repulsive to the taste, and unless the patient be left in ignorance of its nature. There remains the delicate question of the attitude of the physician in respect of marriage of markedly neurotic women. Taking as a cardinal principle that there is no form of mental disease in which marriage can safely be recommended as likely to prove of benefit, bearing in mind also that in discussing such a question one ought in fairness to remember the possible consequences to the unfortunate husband, it is evident that the responsibility of the physician is exceedingly grave. It is comforting to know that mere hysteria, *per se*, does not appear to have any predisposing influence in this direction, and in the event of a woman suffering from any other form of nervous instability, the physician's advice ought unhesitatingly to be in favour of abstinence.

PUBLIC SCHOOL SURGERY.

THE Presidential Address delivered before the Bristol Medico-Chirurgical Society by Mr. Arthur W. Pritchard, and published in the current number of the *Bristol Medico-Chirurgical Journal*, deals with a subject which, for many reasons, entitles it to be carefully read by practitioners. Under the heading of "School Surgery," Mr. Pritchard discusses at length his professional experience as medical officer to a large public school—Clifton College—and gives an interesting description of the accidents and other surgical emergencies, in connection with the School games, which have come under his notice during the past few years. The games mentioned are football, runs, athletics, and cricket, and speaking of the first he admits that when played under the Rugby rules it is marvellous that serious mishaps do not occur more frequently than they do. Still, he adds that most of these contests finish without anyone complaining of any serious hurt. Fractures in football games are stated to be comparatively rare. The most common injuries are to the muscles, and of all those in the body the muscles of the thigh suffer most. It is interesting to note that separation of the anterior superior spine of the ilium by muscular action is a well-known accident; the symptoms of this are very definite—namely, loss of power in the thigh and a sensation of something having given way near the hip during a violent muscular effort. The injury in question is one which is probably seldom seen outside a public school, and hence the text-books on surgery have but little to say about it. One of the commonest

lesions met with in the football field is hæmatoma of the ear, in consequence of the ears being severely crushed in the "scrimmage." Simple as this affection might seem to be, Mr. Pritchard points out that it is by no means simple in reality, inasmuch as, unless it be successfully treated, the patient will be left with one very ugly ear for the rest of his life. Despite, however the best care in some cases, an unsightly thickening of the affected auricle remains. It is worthy of note that on one occasion the author was called upon to treat an alarming accident, namely, a rupture or fracture of the trachea. In this case there was a tender spot about three rings below the cricoid, the throat, neck, face, and chest quickly became emphysematous, and there was great difficulty in swallowing but not in breathing. Fortunately, however, in ten days time the symptoms had entirely disappeared. In regard to the question as to the comparative danger to life and limb between Rugby and Association football, Mr. Pritchard holds that as far as his experience goes, the former is more dangerous in respect to injuries to muscles and joints, while in the latter accidents occur less frequently, but when they do take place they are often more serious. In one Association game, for example, a boy's cornea was cut across by the ball, from which a loose tag was hanging, as a consequence of which the eye was ultimately lost. Coming next to the question of "school runs," Mr. Pritchard is of the opinion that this form of exercise does more good than harm, and that in healthy boys it is seldom that any mischief results therefrom. He holds that the value of the lesson of endurance taught by the runs more than compensates for the fatigue and the few accidents which they cause. This testimony upon a much-debated point should be borne in mind by those who have been accustomed to find fault with the head masters of schools for allowing "runs" to take place. Under proper safe-guards, we quite agree with the author, that the form of exercise in question is both salutary and expedient. In comparison with football, cricket is remarkably free from danger, and the author points out that it is seldom that any accidents occur during a match at cricket. This testimony is in accord with that of the greatest of living cricketers Mr. W. G. Grace. Injuries to the hands from playing fast bowling without gloves, broken noses, and cut lips are the usual forms of injury met with at cricket. Of course, it is only to be expected that out of a large community of boys in a public school, there should be some whose inclinations would prompt them to malingere. But it is of interest to learn that at Clifton the tendency of the boys is to make the best of any injury, so as to return to their work and to the games with as little delay as possible. However, the author relates his experience of one malingere. The patient was a small boy who had an abrasion of his skin which positively refused to heal. After some time it was found that the wound was kept from healing by the boy brushing it with some developing solution used in photography. The same boy, on other occasion, alleged that he had swallowed the bulb of a thermo-

meter which had been placed in his mouth, the bulb having hestated broken off. But his previous history was against him, and after four days quarantine, nothing having occurred, he was despatched to school again and properly punished. Space will not permit us to refer further to the many other features of surgical interest contained in this address on "School Surgery." Nevertheless, we are glad to see that Mr. Prichard's experience leads him to the conviction that school games, although necessarily associated with some risks, are nevertheless highly advantageous, and that the advantages far outweigh the risks by reason of the immense gain which ensues both to the health and strength of body, mind, and character of the boys.

STREET PAVING.

THERE can be no more certain index of the degree of administrative evolution attained by any civilised community than the state of its roads and streets. In the country the question of the best material for the highway paving has long ago been settled by the adoption of the broken stone introduced by the Scotchman, MacAdam. In busy towns, however, where the macadamised roadway and its congener, the granite cube, has been generally abandoned, the problem has yet to be solved. Of late years great advances have been made by the construction of streetways made of asphalt, wood, or concrete, but the general verdict as to the most suitable of the various rival plans is still unpronounced. In one form or another the question is continually cropping up at the meetings of Vestries and of other bodies charged with the details of local administration. Its settlement in the present imperfect stage of knowledge and experience is surrounded with many doubts and difficulties. The various arguments advanced in favour of this or that particular material may be classed under two main headings, the popular and the scientific. To the average man the chief points to be considered as regards the roadway would be cost, cleanliness, noisiness or otherwise, and its suitability for horses. Turning to the three staple substitutes for macadam introduced in recent years we find that both asphalt and concrete, in certain states of the weather, are dangerous to horses. On the whole, wood offers a better foothold than either if properly looked after, and it is also less noisy. There are, however, certain objections against wood, such as, for instance, its cost, the rapidity with which it wears out, and its bad smell in hot and damp weather. This last-mentioned drawback brings us to the scientific aspects of wood-paving, apart from the mere lessening of noise and the indirect saving in wear and tear of horse-flesh. There can be no doubt that the popular mind has become possessed of a firm belief that the effect of the wooden roadway is to cause a large amount of disease. This idea has probably sprung in the first instance from a vague general association on the part of most people of evil smells with noxious diseases. There is, however, an absolute lack of evidence that the wood-paving

encourages the development of pathogenic micro-organisms. So far from that, it seems likely that the majority of microbes exposed on an impermeable pavement would be speedily destroyed by the combined action of sunlight and air. The æsthetic objection would, doubtless, be to a great extent overcome by a more systematic and thorough system of scavenging. Indeed, it may be broadly stated, without much fear of contradiction, that an evil street smell is almost invariably the result of neglect on the part of the local authorities. For all that, no positive proof exists against the agency of wooden streets in the spread of infection. Indeed, so far as we know, the only scientific investigation made into the special conditions of wood-paving are those of Dr. Wynter Blyth, who showed there was more ammonia in the under layers of the gutter than of the central blocks. A well-laid paving of hard wood, however, should be practically waterproof, and would not permit the percolation of moisture which presumably lies at the root of the phenomenon ascertained by Dr. Blyth. Further investigation into the facts of the case by scientists is much needed, for the subject involved is one of great practical importance to the community. At present there are no established conclusions, and the ratepayer is consequently too often at the mercy of the interested commercial speculator and of official wire-pullers. The result of this chaotic confusion and bewilderment is to be seen in the patchwork state of the streets of our great cities. The road-area of an average London district, for instance, presents a veritable mosaic of wood, macadam, granite cubes, asphalt, and concrete, that cannot fail to exact an immense unnecessary tax from the unfortunate horses condemned to travel over such constantly varying surfaces. The cost of the annual maintenance and repair of roads is hardly realised by the ordinary citizen, who rarely troubles himself about the administrative economics of his peculiar locality. Still less does he form any adequate conception of the vast sums of money required to carry out the substitution of modern paving for the old macadam roads of a district.

Notes on Current Topics.

A Sanitary Death-Trap.

A FEW weeks since a remarkable action was tried before the Edinburgh Court of Session. It illustrates in a startling manner how householders are at the mercy of landlords and workmen, as regards the wholesome condition of their dwellings. The pursuer claimed damages from a property company through their failure to put a house let to him in proper sanitary repair. The evidence showed that two drains were cut off and sealed by the company's workmen, who, however, did not disconnect the drains from the main sewer. The sealed drains ran, one under the lobby, and the other under the kitchen and sitting-room. One of the disused drains had an opening immediately under the kitchen sink. The pursuer's

family suffered from much illness, and two of his children died of diphtheria. Lord Kincairney, before whom the case was tried, awarded damages to pursuer to the extent of £150 and expenses. His remarks on the scientific evidence are worthy of careful note. One medical man attributed, without any hesitation, the death of the children to the bad drainage. Two other doctors, although they agreed that diphtheria and bad drainage were often concurrent, gave more hesitating evidence. But, said the judge, at present the origin of the disease was a moot point, and it did not matter vitally whether the sewage gas acted directly in producing diphtheria, or indirectly by lowering the system and rendering a person more prone to attack. This appears to be a just and common-sense view of the case. The defendants, it should be noted, made no attempt to bring forward expert evidence to controvert the view that the bad drainage led to the illness.

Lunatic or Criminal?

LAST week an elderly maiden lady was sent to prison for twenty-one days by a London magistrate, under the following extraordinary circumstances. The evidence showed that for upwards of three years she had subjected the congregation of a Clapham church to persistent annoyance. She was in the habit of promenading the aisles during the service, and of singing discordantly, commencing before the rest of the worshippers and continuing after they had ceased. The prisoner had no excuse to offer for her conduct, but complained that the clergy refused to administer to her the Holy Communion. Now, it appears to us that such conduct as that of the accused is not that of a sane and responsible person. Yet the magistrate, by sending this poor eccentric old woman to prison, virtually declared she was responsible for her action in disturbing the service. Then, again, why was the defendant refused admission to the Holy Communion? If on account of her eccentric mental condition, then the clergymen who brought the charge cannot fail to see the injustice of the magistrate's decision. Of course, it is clear that congregations must be protected against disturbers, but it certainly seems on the face of it that this unfortunate lady should have been consigned to a lunatic asylum rather than to a gaol. At any rate, the case should be carefully inquired into, and deserves the immediate attention of the Home Secretary. It has been pointed out in these columns time after time that a great many cases which are sentenced in the police courts offer *prima facie* evidence of insanity. As a rule, magistrates are utterly ignorant of the most elementary facts of mental aberration. What is wanted is an independent official expert in insanity, to whom all doubtful cases should be referred for investigation and report. If some such course were adopted there can be no doubt that the shadow of a grave reproach would be lifted from the police-court administration of this country.

The Irish Conjoint Examinations.

THE return of the Committee of Management for the Dublin Colleges, with respect to the last summer examinations, has just been presented, and no explanation is offered for its issue more than six months after date. The preparation of so meagre a statement could not occupy more than a few hours, and its presentation to the Colleges after such a delay is an absurdity which, it is to be hoped, will not be repeated. The return shows a slight decrease in the number examined, from 219 in July, of 1894, to 212 in July, 1895, the falling off being especially visible in the third and fourth examinations, owing to the operation of the five years system, which encourages the student to waste his third year, inasmuch as there is no examination to be passed in that period. The rejection percentage, taking all the examinations together, reached the high ratio of 57.5 per cent., but the explanation of that high "mortality" is to be found in the preposterous severity of the physiology test at the second and third examinations. The return does not give the proportion of candidates victimised in that subject, but it shows that the rejections at these two examinations at which it is the salient subject were respectively 65.1 and 75.7 per cent., and it is notorious among students and teachers that the physiology and histology tests are responsible for this heavy slaughter. We observe that the Committee of Management proposes to remedy this abnormal severity of the test by defining and limiting the subject by a syllabus, but we do not anticipate that the adoption of such expedient will have any material effect until a root and branch reform of the method of examination is effected. Any examiner who is minded to submit candidates to an unanswerable examination and to frighten and discourage them, can do so as effectually within the scope of a syllabus as in any other way. This part of the examination has been for years a scandal and a blot upon the Dublin conjoint system. We do not believe, no one believes, that the Dublin student presents himself in physiology in so unprepared a state as to justify the persistently excessive rejections, and we submit that it is high time that the colleges should intervene for the protection of the students.

Antiseptic Books.

THE Paris Academy of Medicine has been engaged upon the discussion of a communication by M. du Cazal, in which he records his experiments respecting the danger of infection from books. It goes without saying that he found abundant microbes on the pages of books, especially those lent out from libraries, and that he found it impossible to effectually disinfect them. The sequence, we assume, is that no one should read a book unless it is uncut and fresh from the press, and that, even in that case, the reader will have to run the gauntlet of a lesser army of microbes. The question suggests itself, where is this microbe craze to stop? or at what point does it become ridiculous? Is there any article touched from morning to night in our daily life which is not open to the same objection in a greater or lesser degree than the circulating library

book? The most rabid antisepticist accepts with satisfaction a bank note reeking and saturated with germs, and carries it about with him into every sick chamber into which he enters. Where is the consistency?

Appointment of Registrar of the Branch Medical Council for Ireland.

THE election of a successor to Dr. Heard, the Registrar, who recently resigned, took place on the 16th inst. Several candidates presented themselves, including Mr. Houghton, the Assistant Registrar, Mr. Greenwood Pim, Secretary of the Conjoint Examination Board, and Mr. Wilson, sometime Librarian and Assistant Secretary at the Royal College of Physicians. Mr. Wilson was the only one of these candidates who possesses a medical qualification, and he was eventually elected. We understand that Mr. Houghton has resigned his office as Assistant Registrar, the salary of which office is £50 a year.

The "Mother's Friend."

THE extent of the trade in infant hypnotics may be judged from the evidence presented in a recent prosecution by the Pharmaceutical Society of England against a grocer for selling one of these nostrums. This concoction, which is called the "Mother's True Friend," was a mixture of Epsom salts and morphia, to the amount of one grain of the latter to the ounce of water. The defendant pleaded that he had sold two gallons a week of the liquid for the last twelve years, but he admitted that, for the privilege of doing so, he had paid already £25 as fines to the Pharmaceutical Society upon five separate convictions. He was fined another £5.

The Risks of Anæsthesia.

IT is stated that 61 deaths have occurred within the past year in the United Kingdom, of which 52 were from the administration of chloroform. This would be a fearful indictment against the use of that anæsthetic if we only knew what was the relative proportion of patients submitted to its influence and to the influence of other anæsthetics. In other words, if the number of chloroform cases were fifty-two times the number of nitrous oxide cases chloroform would be no more dangerous, although it might have caused 52 deaths for one death caused by the latter anæsthetic.

The Study of Pharmacy—Important Judgment.

THE Dublin Queen's Bench Court delivered judgment last week upon a question which has been the subject of much controversy for years. The Pharmaceutical Society of Ireland had refused to admit to examination a student who presented a certificate of apprenticeship *not* from a recognisable firm of qualified chemists, but from the manager of the pharmaceutical department of a limited liability company in the general trading line. The candidate appealed to the Court against the decision of the Society, but the result has been unfavourable to him. The judges agreed that the certificate of the manager was not a legal compliance with the regulations, but some of

them expressed their opinion that the regulation might operate harshly towards candidates, and that a more elastic arrangement might be advantageously made.

The Viavi Treatment.

AT an inquest held recently at Brighton it transpired that the deceased had died from apoplexy, although she was only 24 years of age. She had been subjected to the "Viavi" treatment for anæmia, and had taken medicines in accordance therewith, but the agent, who was examined, did not know what those medicines contained. The points in the case worthy of notice were that a sympathetic lady paid out £3 6s. for the Viavi medicines, and that the jury, without having the medicines analysed, returned a white-washing verdict.

The Health of Johannesburg.

NOW that the eyes of the world are concentrated upon Johannesburg, it may be of some interest to refer to the latest reports respecting the salubrity of the city, as testified to by the medical officer of health. The latter holds that the climate of Johannesburg is good and conducive to health. On the other hand, his reports show that the place is most unhealthy, owing to defective sanitation. During the month of October last the total death-rate for all diseases corresponded to 38.4 per 1,000 per annum, or 9.6 per 1,000 more than for the previous month. In the first month named no less than 331 interments took place in the public cemetery, of which 193 were natives and coloured people and 132 Europeans, while six only belonged to the Jewish population. It may here be observed that the total black population in Johannesburg has been estimated at 60,000, and the whites at 70,000. So far as the drainage is concerned, there is no efficient sewerage system, hence the sanitary arrangements are appallingly horrible in some parts of the town. For the most part the bucket system prevails with all its attendant evils. Again, a general consensus of opinion shows that the water supply is very much at fault, that a scarcity often occurs, and that the water is far from wholesome. It is further pointed out that the death-rate among the Kaffirs is exceptionally high, the causes being accidents, pulmonary disorders, and typhoid fever. After all Johannesburg, for many reasons, does not appear to be a desirable place in which to reside at the present time.

Should Medical Men Wear Beards.

THERE is no doubt that the hirsute appendages of men, no matter where they may be, can and do become the convenient resting-places for micro-organisms. It is for this reason that the process of shaving becomes so necessary before the surgeon, a true disciple of Lister, proceeds to cleanse the skin of the part upon which he is about to operate. The recognition of these facts has drawn attention to the alleged inexpediency of medical men wearing beards. A correspondent to an American medical contemporary has pointed out that in a medical man's beard the infection

of zymotic disease can be readily conveyed to healthy households. He even cites cases in which the infection of diphtheria and scarlet fever have been so communicated. The *New York Medical Record* referred to the same subject some time ago, and our contemporary raised a storm around its editorial sanctum by suggesting that medical men would be wise to restrict their beards to modest and sanitary limits. Indignant correspondents, however, wrote to say that they had for years worn long and breezy whiskers and beards, and that they had no intention of depriving themselves of these appendages. After this no more was said on the subject, but since then it has been revived by the correspondent above referred to, in a somewhat active manner. Of course, we do not deny the possibility of infection being conveyed by means of a medical man's beard or whiskers, but such a mode of infection is, to say the least, highly improbable.

The Untruthfulness of Morphinomaniacs

THE mental and moral destruction which occurs in a victim to the morphia habit is a fact which unfortunately has been only too frequently demonstrated. This point has led to some discussion respecting the expediency of rejecting the testimony in a court of law of those who are known to be addicted to the use of morphia. One authority has even gone so far as to say, "I would not believe a man who is a victim of the morphia habit on oath." No doubt the moral obliquity as to truthfulness present in such a person would be perfectly uncontrollable, under any circumstances, and unrestrained, even although he had sworn to tell the truth. But before coming to any definite decision upon the question of receiving or rejecting the evidence of such a witness, it would first of all be only expedient to determine what constitutes a person whose mental and moral capacities have been tainted by the use of morphia.

The Adrenal Treatment of Addison's Disease.

IT must be admitted that the supra-renal-capsule treatment has failed to answer the expectations originally formed of it. In addition to the case read last week by Dr. Ringer, before the Clinical Society, we have received particulars of an unsuccessful case treated by Dr. Murrell, at the Westminster Hospital. The patient was a comparatively young man, and as the symptoms were of less than six months' duration the failure is the more remarkable. There could be no question as to the activity of the preparation employed, as special precautions were taken to obtain a supply of absolutely fresh adrenals. The animals were slaughtered daily in the presence of Dr. Copeland, the house physician, by whom the glands were at once removed and administered to the patient. Both sheep and calves were used, and thanks to the kindly co-operation of a friendly butcher interested in the amelioration of suffering, an ample supply was always at hand. The initial dose was a drachm, but this intensified the nausea and vomiting, and failed to increase the blood pressure. The dose was then reduced to fifteen grains three times a day, but

the pigmentation became more pronounced, and the patient gradually lost flesh and strength, and died on the thirty-seventh day of treatment. The correctness of the diagnosis was confirmed by the post-mortem examination. Addison's disease is of somewhat rare occurrence, but there must be many cases scattered throughout the country, and it would be interesting to learn if other observers have failed to obtain good results from the new treatment, and especially if any untoward effects have been noted. The natural tendency is to report successful cases and to ignore those terminating unfavourably.

"The University of Philadelphia.

DR. BATEMAN, the active general secretary of the Medical Defence Union, did good service in pointing out last week in the *Times* the precise facts in regard to the status of the so-called "University of Philadelphia," of which so much has recently been heard. He states that this so-called university had its Charter revoked in 1879 under the following circumstances: "By the Legislature of 1871, a joint special committee was appointed to investigate the alleged issue of diplomas by the 'American University of Philadelphia' and the 'Philadelphia University of Medicine and Surgery.' This committee, after taking evidence in the City of Philadelphia, recommended that the Charters of the two so-called universities should be revoked, both institutions having been guilty, in the opinion of the committee, of selling their diplomas to persons who had not followed the prescribed course of studies and of violating the franchises granted them." Subsequently proceedings were taken against the Universities and the Charters forfeited. The Charters also of the Electric Medical College of Pennsylvania were similarly revoked on September 30, 1880. It is to be hoped that the newspaper press throughout the country will take note of these facts, and bring home to their readers how American quacks coming to this country are able to deceive the public. Quacks of this ilk can only be successful in their campaigns by means of the fraudulent assumption of titles; without titles they would be "nowhere;" hence, in order to counteract their practices, it is clearly expedient that the public should know all about the value of these American M.D.'s.

Eye Troubles of Bicyclists.

THAT some ocular troubles should be associated with bicycle riding is perhaps not surprising, but so far only two cases of the kind seem to have been placed on record. One is recorded by Dubois in the *Annales d'Oculistique* for last year. The patient was a professional rider, aged twenty-four, who was attacked with a peculiar visual disturbance during a twenty-four hours' race in very cold weather. About the eighteenth hour he noticed that his vision was disturbed, that he steered badly, and that he ran into other machines. A diffuse haziness of both corneæ was found, without superficial lesion. Under the influence of warmth and rest the vision began to improve, and the next day the corneæ had regained their normal

appearance, and the vision its usual acuity. The trouble, in the opinion of the author, was due to the cold—a possible explanation in view of the fact that during the race the thermometer fell to 10° below zero Centigrade. The second case is published in the *Archiv. Med. de Toulouse*, also for last year. Clavelier, under whose care the patient was, records that a man, aged 32, consulted him after he had ridden a race of twelve kilometres, in which a very rapid pace was accomplished in the latter half of the ride. The patient had been seized with severe palpitations, which had scarcely terminated when a sudden diminution in the vision of the left eye supervened, the sight falling to one-fourth. The right eye remained normal. Ophthalmoscopic examination showed traces of numerous retinal hæmorrhages. Examination of the heart yielded nothing, and the urine was perfectly normal. There was no rheumatic, syphilitic, or alcoholic history; no anæmia, and no disease of the digestive organs. The conclusion was then arrived at that in some way the bicycle race had caused the lesions.

The Abolition of the Gargle.

THE length of time which it takes for any scientific fact to receive general recognition is equalled, possibly even exceeded, by the difficulty experienced in inducing practitioners to discard measures or methods which more recent experience has shown to be inadequate, inefficient, or even injurious. It is to be feared that the time-honoured gargle falls into this category, but even its antiquity, coeval though it be with the poultice and the leech, cannot blind us to the fact that it necessarily falls short of the mark when the diseased tissues are on a plane behind the posterior pillars of the fauces. Even a casual study of the conditions which obtain in the act of gargling as usually understood, will show that the fluid is kept in front of the lowered soft palate, so that it is impossible for any effects to be exercised on tissues posterior to that structure. A gargle, as ordinarily employed, is, therefore, only a mouth wash. Under these circumstances, it is really surprising that it should have been reserved for Mr. Lennox Browne to enter a protest against the continuance of a practice which is not only useless but, in presence of actual inflammation, is exceedingly painful, and may be injurious. Mr. Browne describes, however, another method of gargling, using the term gargling in the sense of trickling a fluid through the mouth into the pharynx, which is free from one, at any rate, of the objections already alluded to, viz., the method of Von Troelstch, for which the directions are as follows:—"Take a tablespoonful of the gargle in the mouth, hold it in the back of the throat with the head thrown back, then, closing the nose with the finger and thumb to prevent entrance of air, open the mouth and make the movements of swallowing without letting the liquid go down the throat." By this means the medicated fluid can, it is true, be brought into contact with the pharyngeal tissues, but the process is by no means easy to carry out in an effectual manner, and in the majority of instances it is quite out of the question. Gargles, again, are quite

inadmissible in cases entailing the dorsal decubitus, such as diphtheria, in which cardiac failure has to be sedulously guarded against. Another obvious objection to gargles is that they must perforce comprise only the most harmless ingredients, if we are to avoid subjecting the patient to the danger of poisoning in the not improbable event of any portion of the fluid escaping control and finding its way down the œsophagus. Moreover, solutions thus employed must not contain any considerable quantity of an active ingredient, because they will come into contact with vastly more healthy, than diseased, tissue. The moral is that gargles should give place to more scientific and precise methods of applying topical agents to diseased surfaces in the throat, especially in children, in whom gargling of any sort is virtually an impossibility. The future, therefore, is toward irrigations, sprays, lozenges, and, in the case of children, to medicated confections.

Calomel—A Warning.

OUR contemporary, the *Chemist and Druggist*, calls attention to the liability on the part of calomel to undergo decomposition under certain conditions, with the result of the production of a certain proportion of corrosive sublimate. Reiterated observation and experiment have shown clearly enough that if mixed with sugar and put up in powders an appreciable quantity of the more active salt sooner or later makes its appearance, although the amount, it is comforting to know, has never been large enough to permit of exact estimation of the amount present. The nature of the decomposition is, however, such that the eye can detect the change in a trace of black mercurous oxide, formed simultaneously with the mercuric salt, giving the white calomel a grey tint, and it is quite conceivable that such a powder might produce unwished for effects in an infant. Our contemporary raises the further question as to whether chemically pure calomel is a trustworthy therapeutical agent. As a cholagogue the sublimate is stated to be far more active than the sub-chloride, and it is hinted that the efficacy of calomel in the past may have been dependent on its admixture with or conversion into the more active compound. This is a point which it is worth while clearing up, because, if the effects attributed to calomel are really due to the presence of an impurity, it is as well that we should be made aware of the fact.

The First Female "Master in Surgery."

MISS LOUISA ALDRICH-BLAKE has achieved the distinction of becoming the first Master in Surgery of the University of London. She has, by winning this distinction, capped an honourable career as a student at the London School of Medicine for Women, having distinguished herself in every part of her student course. Miss Blake is Curator of the Anatomical Museum at the Royal Free Hospital, London.

AN epidemic of measles is at present raging in Maidstone, which has necessitated the closing of all the elementary schools in the town.

Typhoid from Ice.

SOME months ago we published an abstract of the report of the Paris municipal analyst which revealed the fact that much of the ice served out in clubs and restaurants is of inconceivably filthy origin and laden with nameless abominations. It is now stated that the military officers at Rennes have suffered from a typhoid epidemic which has been traced to the ice which was used to cool the champagne at a banquet. The ice had been taken from the neighbouring river at a point where the town sewers empty themselves.

Over-zealous Sanitation.

WE have many times deprecated the interference of public analysts in cases of adulteration of a technical and legal character, but which injure nobody and are of homoeopathic dimensions as regards the amount of the adulterant. We note that traders have been prosecuted, within the past week, for selling lemonade containing a sixth of a grain of lead to the pint, and for selling preserved peas with less than a grain of copper to the pound. It must be admitted that if an individual swallowed a keg of lemonade or consumed a dozen tins of preserved peas, he would probably become sick, but it may be doubted that the most gluttonous person would, take enough of either article to harm him in the slightest degree. It is surely not necessary for analysts to go in search of such infinitesimal adulterations, considering that almost every article of consumption is largely sophisticated, and it appears that the only effect of such prosecutions is to bring the law into contempt and to deter sanitary authorities from activity in the suppression of adulteration.

A Bengali Professor.

MR. J. C. BOSE, Professor of Physical Science in the Presidency College, Calcutta, is almost the first Bengali to distinguish himself in the field of original research. A paper he has recently written on the polarisation of light has been accepted for publication by the Royal Society, and a grant, it is understood, is to be made from the funds of the institution to assist the investigations he is conducting in the Presidency College Laboratory.

The Inter-Colonial Medical Congress.

GREAT preparations have been made for the meeting of the Inter-Colonial Medical Congress at Dunedin, New Zealand, in February next. From Australia steamers have been arranged to leave all the chief ports in time for the opening of the Congress. The attractive programme of the "trips" available for those who attend the Congress has probably influenced a good many of the members of the profession in Australia to make their journey to Dunedin. New Zealand seems to abound in scenery of the loveliest description.

Pasteur.

A STATUE is to be erected to Pasteur, in Paris, and the French Government have started the subscription with a contribution of £400.

Infectious Disease in Birmingham.

BIRMINGHAM is particularly unfortunate in its experience of infectious disease, and appears to be in a chronic condition of epidemic visitations. Last week the Health Committee of the Aston Board reported a continued outbreak of measles, in consequence of which a Board School had been closed. Diphtheria had broken out in another school; there had been sixty cases altogether, forty-five of which had been of persons directly or indirectly connected with a certain school, and there had been fourteen deaths among them. Scarlet-fever showed no abatement. All these disquieting reports from a city so advanced in intelligent local administration as the capital of the Midlands, simply emphasises the imperfection of our sanitary preventive methods. From the modern point of view the whole of this lamentable sickness, with its consequent suffering and death, is preventable, and every single life lost in this way is an unnecessary loss to the community.

River Fish and River Pollution.

THE good folks of Carmarthen are bewailing the decrease of salmon in the Towy. Their story is the familiar one of a once prosperous fishery failing steadily beneath the fostering hands of a Board of Conservators. The complaint they make is not without humour, namely, that before the guardian body was created there were many more salmon in the river. The leading Carmarthenshire newspaper asks whether the breeding of fish cannot be reduced to a science as well as the breeding of dogs and horses. Certainly, there is a great future awaiting scientific pisciculture. It would be extremely illogical, however, to turn shoals of fish into water that for some reason or other fails to support its present quota of fish. Nor is it of much use to limit the number of anglers on the river. What we would advise the Carmarthen Bay Board of Conservators to do is to enforce the Rivers Pollution Act to the utmost letter, so as to restore the purity of their beautiful river. If this is done, the salmon will soon regain their former supremacy in the struggle for existence, which is specially keen in river life.

Public Health Examinations.

OF late years the standard of requirements in public health examinations has been considerably raised. It will be of interest, therefore, to the profession generally and to medical officers of health, students of sanitary science, and those who contemplate taking out the D.P.H., to have an idea of the increasing scope and tendency of the examination tests. It is with much pleasure that we publish in another column complete sets of questions lately put to candidates for the diploma in public health in no less than three of our leading Universities—Oxford, Cambridge, and Durham, and at the London Conjoint Board. These papers have been specially forwarded to us for publication by a gentleman who holds two of the qualifications for which they were set, and they will appear in a series extending over the next few weeks.

MISS MARY DARBY STURGE, who passed the examination for the degree of M.D. London, last month, received her early training at Mason College, Birmingham, proceeding afterwards (in 1888) to the London School of Medicine for Women, and the Royal Free Hospital. She took Honours in Anatomy at the First M.B. Examination, and was subsequently appointed Demonstrator of Anatomy at the London School of Medicine for Women.

AN old Anglo-Indian officer attributes the increase of typhoid fever among the young soldiers in India to their pronounced teetotal habits. They drink, he claims, a great deal too much lemonade and other similar beverages, and he is of the opinion that every Englishman under the age of 25 who lands in India should go through a course of whisky and soda.

A MEDICAL Club, Limited, has been founded in Liverpool, with a capital of £1,000 in £2 shares. The objects are to establish and maintain a club for members of the medical profession, in particular those practising in Liverpool and its vicinity. The directors have been decided upon to the number of 15, of whom 10 are general practitioners.

It has been estimated that a case of quadruplets occurs but once in three hundred and fifty thousand to four hundred thousand births. But if the proportion were one in a million, or even a billion, there would always be two persons who would regard the prodigality of Nature as an act of unkindness.

DR. WM. BERRY has been unanimously appointed Medical Officer of Health for the important Borough of Wigan, Lancashire. The appointment is a popular one, as Dr. Berry was born there, is a justice of the peace, and highly respected.

MR. H. A. ALBUTT has been fined at Leeds for using the titles M.R.C.P., L.S.A., his name having been removed from the *Medical Register* some time ago.

WE regret to learn that Dr. C. R. Illingworth is now an inmate of St. Luke's Asylum.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

NEW APPOINTMENTS IN THE UNIVERSITY OF EDINBURGH.—The Edinburgh University Court has appointed Mr. George Berry, M.B., C.M.F.R.C.S.E., &c., senior ophthalmic surgeon to the Royal Infirmary, to the post of Lecturer to the University in Ophthalmology, vacated by the resignation of Dr. Argyll Robertson. Dr. Affleck was appointed an additional examiner in medicine in its bearings to public health.

MEDICAL FEES AND SHIPOWNERS.—An important case affecting doctors and shipowners has recently been decided in Ayr Sheriff Court. The question raised was as to the liability of a shipowner for surgical attendance rendered to a seaman on board ship in a home port. Dr. Charles M. Stewart, of Glasgow, sued the Garnock Steam Shipping Company, Limited, for £1 1s. for professional services rendered to a fireman on board the company's s.s. *Burnock*, who had sustained injuries through falling down into the hold of the steamer while she was lying in the harbour of

Glasgow. The defenders denied liability on the ground that the ship being in a home port the master was not entitled to pledge the shipowner's credit for surgical attendance. The Sheriff, however, found that the Merchant Shipping Act of 1854, section 228, subsection 3 (re-enacted in the Act), and which provides that "the expense of all medicines and surgical or medical advice and attendance given to any master, seaman, or apprentice whilst on board his ship, shall be defrayed by the owner of such ship," applied to the present case; judgment with costs, was given accordingly.

STILL ABOUT THE OYSTERS.—At a meeting of the Stirling Police Commission on the 14th inst. a letter was read from the Junior Health Officer of Glasgow to the Secretary of the Local Government Board, stating that he had been informed by the cook who was engaged at the County Ball that some water which he drew from the tap in the hall kitchen both smelt and tasted badly, and that if the subsoil was exposed to pollution there appeared to him fair grounds for conjecture that the epidemic attributed to oysters might be traced to defective drains. The Master of Works, Stirling, however, submitted a report on the condition of the water-pipes at the Public Hall, in which he states that the service pipe was opened and found to be perfectly dry throughout its whole length, there being no appearance of sewage or subsoil water. The service pipe was perfectly sound and the pressure of water at its maximum. Dr. Wilson, Medical Officer of Health, Stirling, also submitted a report dealing with the whole subject, concluding his report by stating that the cause of the outbreak of the fever still remained a mystery.

EXAMINATION PAPERS FOR THE DIPLOMA IN PUBLIC HEALTH AT THE UNIVERSITIES OF OXFORD, CAMBRIDGE, AND DURHAM, AND THE CONJOINT BOARD OF ENGLAND. (a)

OXFORD, NOVEMBER 25TH, 1895.—PART I.

No. I. — *Chemistry and Physics.*

1. DESCRIBE the treatment of raw sewage (a) by means of slaked lime; and (b) by means of ferrous sulphate or ordinary green vitriol, with or without the supplementary use of lime. What proportions of the respective precipitants are usually employed per 1,000 gallons of raw sewage, and what are the chemical and other effects produced? How do the results compare with those obtainable by sewage irrigation?

2. What are the difficulties attendant on the combustion of house-refuse in the class of furnaces known as "destructors"? What are the conditions requisite for complete combustion; how are they sought to be effected; and with what results?

3. Within what range of proportion is common salt usually met with as a constituent of drinking water? What are the sources of the common salt present in different varieties of drinking-water? Under what circumstances does the presence of a somewhat high proportion of common salt indicate probable sewage contamination?

4. (a) State approximately the relative proportions by volume of oxygen and nitrogen in atmospheric air, and in the air dissolved by uncontaminated river-water. (b) Assuming that at mean temperature, and under an effective pressure of 30 inches or 760 m.m. of mercury 100 volumes of water dissolve approximately 3 volumes of oxygen, what, under standard atmospheric conditions, is approximately the actual volume of oxygen dissolved in 100 volumes of water, in accordance with Dalton's law of partial pressures? (c) What is approximately the weight of oxygen dissolved, under standard atmospheric conditions, in 1,000,000 gallons of water, taking 1 cubic foot of oxygen to weigh 0.115 lb., and 1 cubic foot to equal 6.23 gallons?

5. Set forth and discuss the discordant statements that have been made with regard to the rapidity and extent of the disappearance of contaminating organic matter, taking place in running water. What evidence is there as to the means by which the removal of the organic matter is effected?

(a) Examination for the Degree of Bachelor in Hygiene, and for the Diploma in Public Health (D.P.H.) Durham.

6. In what particulars does the atmosphere of a closely-packed room differ from that of the open country? How far are these differences capable of estimation? What are the chief agencies by which the intermixture of different kinds of air is effected?

N.B. Candidates are not expected to answer more than four questions

No. II.—*Chemistry and Physics (Practical).*

1. Determine the hardness of the specimens of water, A and B.

2. Determine the amount of oxygen absorbed in one hour from "permanganate" in the specimen of water, C.

3. Determine the amount of lead, as metal, present in the specimen of water, D.

4. Determine by means of the specific gravity bottle the specific gravity of the specimen of dilute spirit, E.

CAMBRIDGE, TUESDAY, OCTOBER 1ST, 1895.—PART I.
No. I.

1. Discuss critically the respective values of (1) a chemical and (2) a bacteriological examination of drinking-water.

2. What quantities of carbon-dioxide, water, and combined nitrogen are excreted daily by an adult man? What amount of fresh air is required per diem to maintain in health a person continuously inhabiting a room? What quantity of water does an adult need per diem for drinking, cooking, ablution, and other domestic purposes?

3. Discuss the value of attempts at the disinfection of houses by means of fumigation. What disinfectants are usually employed for this purpose, and how are they respectively prepared? How many grains of sulphur dioxide are evolved by the action of 150 grains of sulphuric acid on copper?

4. Describe the process of bread-making, and explain the changes which take place in the flour. Upon what data would you give an opinion of a sample of flour submitted to you? Explain briefly any analytical procedure you would adopt in order to arrive at an opinion.

5. Explain the various methods in use for the softening of hard water. Describe accurately how you would prepare the reagents for determining the hardness of water, and also how the determination of hardness is made, calculated, and expressed.

6. In a town of 100,000 inhabitants there are 2,600 deaths per annum, of which 350 were ascribed to diseases of the respiratory organs, 250 to phthisis, 110 to diarrhoea, 120 to convulsions, 50 to enteric fever, and 10 to alcoholism. Point out any deviation from the average and any sources of fallacy in those figures.

PART I.—No. II.

1. A cubic foot of air measured at 32 degrees Fah. is allowed to remain at the same barometric pressure of 30 inches in contact with water until saturated at the temperature of 60 degrees Fah. How and to what extent would the volume of the air be changed? Give calculations. (Vapour tension of water at 60 degrees Fah. = 0.52 inch.)

2. What are the meanings of the terms isobars and isothermal lines? In what respects physically and chemically does the atmosphere at the seaside differ from that of inland towns in summer and winter respectively?

3. What means are commonly adopted for the preservation of articles of food for considerable periods, and how and in what way are these methods liable to affect the health of persons habitually consuming such food?

4. Describe the food-stuffs necessary for the maintenance of life. State the quantities of them requisite for an adult for subsistence only, for average work, and for severe labour respectively. How much bread and how much milk, taken together, would suffice for the subsistence diet of a man?

5. Discuss the significance of the presence of compounds of iron, zinc, and magnesium in water supplies, and state what proportions of these are admissible in drinking-water.

6. In what ways may the atmosphere in a house become contaminated with carbonic oxide, and how may its presence be detected in such an atmosphere?

WEDNESDAY, OCTOBER 2ND, 1895,

Practical Chemistry.

1. Make an examination of the sample of water marked A or B, and write your opinion as to its fitness for domestic use, giving reasons. (State the letter on the bottle.)

2. Examine the samples of air marked 1, 2, and 3, and state what, if any, gaseous impurities they contain.

N.B.—Describe in each case the operations you perform, as well as the results obtained.

DURHAM, WEDNESDAY, APRIL 17TH, 1895.

No. III.—*Sanitary Chemistry and Physics.*

[1. Describe and explain how you would prepare a solution of Potassium Permanganate, of such a strength that 1 cc. is equivalent to 1 mgrm. of oxygen

K. = 39.1, Mn. = 55, O = 16, Fe. = 56.

2. In what forms may nitrogen occur in a polluted well-water?

3. How would you recognise the presence of each of the following gases when mixed with air: (a) Sulphur dioxide: (b) carbon monoxide: (c) sulphuretted hydrogen: (d) hydrochloric acid gas.]

[4. What is meant by the "height of the barometer"? In a siphon barometer, in which the section of the limb open to the air is twice that of the closed limb, through what distance will the mercury fall in the closed limb when the "height of the barometer" falls one inch?

5. Explain the relation between the "head" producing circulation of air in a ventilating system and the "flow" of air produced. State the various means available for producing the requisite head.

6. Define the dew-point. Describe Mason's wet and dry bulb hygrometer, and explain how the dew-point is determined by its means.]

Directions:—The answers are to be made up into two sets, indicated by the brackets on the questions. Each set is to bear the Candidate's number.

Practical Chemistry.

Examine a sample of water (A) for poisonous metals (lead).

Standardise a solution of silver nitrate by means of a given solution containing 3.3 grammes sodium chloride per litre, then estimate chlorides in a sample of water (B).

Examine solution C for an acid (nitric). Determine the amount of acid volumetrically by means of a solution of sodium hydroxide of known abnormal strength.

Standardise a solution of soap by means of a solution of calcium salt of known strength. Ascertain the hardness of water (D), using your standardised soap solution.

(The above paper was not printed.)

CONJOINT BOARD OF ENGLAND, JULY 1ST, 1895.—PART I.

1. What is an Isobar? What inferences may be drawn from the examination of Synoptic Charts?

2. Define Latent Heat and Specific Heat. How may the latent and specific heat of the various forms of Water be measured, and what influences do they exert on the meteorology of this country?

3. Describe Bramah's Hydraulic Press. The smaller piston of such a press is half an inch in diameter, the larger piston is ten inches in diameter; a weight of 12 lb. is placed on the small. What will be the weight placed on the larger?

4. Name the salts of Calcium and Magnesium most frequently found in potable water. How would you determine the presence of these salts, and what practical processes would you employ to remove them when present in inconveniently large quantities?

5. What are the processes employed to preserve Meat and Milk? Discuss the advantages and disadvantages of each.

6. In what substances have the organisms causing Diphtheria and Tetanus been discovered? How would you detect each of them, and describe them?

PART II.

1. You are requested to construct a class-room to hold 25 young adults. With a view to economy of construction, artificial ventilation has to be resorted to. State the

initial cubic capacity you would allow, and the amount of fresh air that would have to be introduced per hour; and sketch the general plan you would adopt for warming and ventilation.

2. What are the differences between atmospheric air and the air of soil? How are these changes produced?

3. You have to advise with regard to the Water-supply of a rural town. What data will you require as to the amount necessary, the amount possible to be obtained, and the reserve necessary for storage in case of drought?

4. Describe the process of Bread-making. What deleterious products may arise during its manufacture, and what are the chief adulterations?

5. Describe some of the principal means of treating Sewage, with a view to its best application to land. How would you arrange for the disposal of urine and slop-water on premises used as a dwelling-house distant from any Public Sewer, and what precautions would you recommend to ensure safety to the inhabitants?

6. Describe the construction of the Syphon Barometer, and how would you make an accurate record of its variations?

JULY 3RD, 1895.—PART III.—PRACTICAL CHEMISTRY.

1. Submit the sample of Water marked I. to quantitative and qualitative examination, so as to pass an opinion as to the fitness of the water for drinking and cooking purposes. The reasons for your opinion and the methods by which you arrive at those reasons are to be briefly stated in your report.

[N.B. The total solid matter of the Water and the absorbed Oxygen need not be estimated.]

2. Make a qualitative examination of the samples of Air marked A and B, with the view of detecting gaseous impurities, and report thereon.

THE TWELFTH INTERNATIONAL MEDICAL CONGRESS.

WE have been officially informed that the Executive Committee has now fixed on the 19th of August, 1897, as the first day of the Congress, which will continue for a week thereafter. Moscow, as previously announced, is selected as the meeting place. The Congress will be under the patronage of the Grand Duke Sergius Alexandrovitch. Prof. F. Klein has been elected president, Kojewnikow vice-president, Erismann general secretary, and Filatow treasurer. Every qualified medical man is eligible; but those who do not belong to the profession, if they possess a scientific qualification, will also be admitted. Members can be enrolled by forwarding their visiting card to the treasurer Filatow, accompanied with a remittance for 10 roubles or 25 francs. This entitles the ordinary member to all the privileges of visiting or taking part in all or any one of the sections. The extraordinary member or member with scientific qualification alone, can only visit the section in which he is most interested. The Congress is to be devoted entirely to scientific work, and will be divided into twelve sections. Contributors are requested to forward a copy of the papers they desire to read at the meeting, not later than January 13, 1897. Time allowed for each paper is strictly limited to twenty minutes in reading, while five minutes will be allowed to any wishing to make remarks. The official language of the Congress will be French. In the three plenary meetings any European language will be acknowledged, but the sections are supposed to be conducted in German, French, and Russian.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

THE GENERAL MEDICAL COUNCIL ELECTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Nothing astonishes me more than the indifference or, at any rate, the silence of the mass of the Irish medical profession at this moment. Let me remind them that our profession is unhappily divided into the governing

few and the governed many. Let me further remind them that the interests of the many have been and are daily sacrificed to those of the few, and that every ill we labour under is due to those ruling few. Sixpenny dispensaries, and advice free with a pound of tea, mark the lowest depths to which any calling could sink. Yet in the face of all these, one of the ruling few in the person of Mr. Thomson, of Dublin, has the modesty to seek our suffrages, and I note that some of the masses are to be found in his train. Intelligent Englishmen and Scotchmen strove for years to obtain a remedy for the grievances of the bulk of the profession, and they did obtain a partial remedy in 1886, by the addition of six direct representatives to the Medical Council. They intelligently used that power but we in Ireland, like the Roman plebs. of old, elected a patrician. Come now, tell me, ye rural supporters of him, what did he so much as even attempt to do for you during his tenure of office?? There are four men now in the field who appeal to the outraged and much-wronged rank and file. If those four men go to the poll the audacious representative of the oligarchy must win. I appeal to Drs Jacob, Greene, Cuming, and McDonnell to meet in Dublin and to produce their list of promises, and let him who has the largest number of promises be selected to fight the fight for the mass of the profession. I do not think that it ought to be Dublin v. Ferns or Dublin v. Dundalk, but it ought to be the case of one of the working Bees v. one of the Diplomavending Drones who have heretofore battened on our debasement, robbery and degradation.

I am, Sir, yours, &c,

THOMAS LAFFAN.

Cashel, Jan. 13th, 1896.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—As two practitioners have discussed in the Dublin daily papers the claims of individual candidates to succeed Dr. Kidd as Direct Representative of the Irish medical profession, we feel called upon, in justice to Dr. Jacob, to point out to the Poor-law medical officers of Ireland that, whatever claims upon their votes Mr. Thomson may have—and we do not wish to depreciate them—Dr. Jacob's services to those officers transcend such claims tenfold in duration, in earnestness, and in self-sacrificing patience and industry.

It is true that Mr. Thomson acted, three years ago, for the *British Medical Journal* in collating information collected by it with reference to the abuses and hardships of the Poor-law medical system, and that he compiled a useful report on the subject; but for many long years before this was done Dr. Jacob had been persistently engaged in preparing the ground which was subsequently occupied by the *British Medical Journal* and Mr. Thomson in instructing and advising the Poor-law medical officers as to their rights—legal and moral—and as to the means to be employed to obtain redress of their manifold grievances. Under his influence chiefly the Irish Medical Association has been engaged for twenty years before any other champion of these officers took the field in vindicating their legal rights and enlarging and protecting their privileges.

Under the influence, to a great extent, of his untiring and unremunerated labour, additional emoluments to the amount of many thousands a year have accrued to the Poor-law medical officers of Ireland, and these officers have been placed in many respects in a position of independence which was previously unknown either to themselves or their employers.

In all these years let us ask what were Mr. Thomson's services to the Poor-law medical officers? Nay, more, what has he done within the three years since he completed his report which should efface the recollection of Dr. Jacob's work? He was co-opted as a member of the Council of the Irish Medical Association, but he rarely attended its meetings or afforded any assistance in its deliberations, and he is now not even a member of the organisation. Meanwhile Dr. Jacob has been working hard to secure superannuation allowances for these officers, and with his own hand drafted the Bill for the redress of their grievances which was introduced to Parliament in the session of 1894 by Mr. T. W. Russell, M.P.

So much for the relative pretensions of these candidates to represent the working country practitioners. As re-

gards the business of the General Medical Council in regulating education and examination, we need only say that Dr. Jacob was one of those who, before Mr. Thomson occupied any public position, reconstructed and reformed the Irish system of medical qualification, and he thereby acquired familiarity with every detail such as no other candidate can lay claim to.

We are convinced that your sense of justice will secure to us the opportunity of making these facts known, and thus preventing Dr. Jacob's great services from being forgotten or overshadowed.

We are, Sir, yours, &c.,

HENRY W OULTON, M.D., Univ. Dub., L.R.C.S.I.,
Medical Officer No. 1 North City Dispensary.

JOHN P. GARLAND, L.R.C.P.I., L.R.C.S.I., Medical
Officer No. 3 North City Dispensary.

LUNATIC ASYLUMS—THE RELIGIOUS QUESTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of the 8th inst., you kindly inserted a few remarks of mine on this important question. These have been followed by an interesting lecture in your last issue, by Dr. Thos. B. Hyslop, in which he deals with the religious aspect of insanity, and he remarks that "A true and philosophical religion raises the mind above a mere incidental emotionalism." Now, granting the truth of this assertion, the difficulty arises which I for one should be content to leave experts in lunacy to determine—viz., which, out of the multifarious forms of religious belief or superstition which pervades all types of humanity, is "the true and philosophical one"? because it must be evident to all, in the vast majority of cases, that religious belief, of whatever kind, is the result of impressions drilled into the infantile mind through the influence of the maternal ancestry, who, therefore, is to decide whether the maternal inculcations of one individual or another is "the true and philosophic religion." Probably the safest type of mind is that which is grounded on common sense and harnessed and disciplined in search after truth, and therefore less likely to soar in regions of imagination and superstition.

Dr. Hyslop also asserts that, "With no religious and no moral obligation the organism is apt to become a prey to the lusts of the flesh." This, I, am aware, a generally accepted view, but is there not a good deal of fallacy connected with it, and is it not frequently put forward as a dangerous and plausible plea to excuse religious superstition on such grounds? Whatever our personal religious beliefs may be, we are bound, in dealing with insanity, to take into account every factor, and it may be open to question whether the cases of religious enthusiasm which culminate in insanity are not greater than those which arise from intemperance in alcoholic stimulants. No doubt in the old stage-coach days, before the introduction of steam, when the public mind was in a comparatively torpid state, there was some excuse for religious excitement, but since then life in its every phase has changed, and with education, rapid means of transit, public entertainments, free libraries, &c., which afford a healthy stimulus to those who choose to avail themselves of them, there is, I think, no longer any grounds for religious enthusiasm or excitement, which so frequently culminate in mental aberration. But whatever differences of opinion there may be on this point, it is to be hoped our experts in lunacy will speak out in no muffled tone in repressing the danger arising from this source.

I am, Sir, yours, &c.,

CLEMENT H. SERS.

Queen's Rd., Peckham, Jan. 17th, 1896.

THE NOTIFICATION CASE—HADDEN FUND.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Will you kindly insert in your next issue enclosed list of subscribers to the above Fund? In answer to many inquiries, I may say that Dr. Hadden was unable to recover any costs from the plaintiff, so that his expenses have been very great. The decision of the full Court on Dr. Hadden's appeal is of such importance to the entire

profession that I would ask all who wish to support the movement to do so without delay.

I am, Sir, yours, &c.,

JAMES CRAIG, Hon. Treas.

DR. CARTER'S THERMO-INHALER FOR ETHER.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Referring to some corrections made by Dr. Dudley Buxton in your last week's issue, we, who had the great pleasure of manufacturing the inhaler in conjunction with Dr. Carter, are much pleased to see it criticised in the MEDICAL PRESS AND CIRCULAR. As, however, general statements are unsatisfactory, Dr. Dudley Buxton would greatly oblige by pointing out in your next week's issue, each of the many grave defects which he considers and, it appears, found in practice inherent in its construction. This information forthcoming may enable us to explain in a plain and, we believe, satisfactory way the cause of the difference of opinion held and expressed by Dr. Dudley Buxton to that held by Dr. Carter and ourselves regarding mechanics in the administration of anaesthetics.

Meanwhile we enclose a table of Dr. Carter's first 22 cases of normal etherisations effected by means of the inhaler under discussion, showing an unprecedented uniformity in the quantity of ether expended on an average per minute, viz.:

In the first series of 18 administrations	31.5 minims.
„ second „	4 „ 31.4 „

Are the uniform results obtained by Dr. Carter in his cases of 85 and 86 facts consistent with the general statements made by your correspondent?

Thanking you in anticipation for inserting this letter in your next week's issue,

We are, Sir, yours, &c.,

KROHNE AND SESEMANN.

London, January 18th, 1896.

Literature.

TURNER'S GUIDE TO THE MEDICAL AND DENTAL PROFESSIONS. (a)

THIS little book may be strongly recommended to all those about to enter the medical or dental professions, except to those very rare examples in the ranks of medicine, men of fortune, who are not likely to be mainly or entirely dependent upon their calling for a livelihood. The book gives full information and is a trustworthy guide in all matters bearing upon a start in professional life. It clearly explains the commercial details as to purchasing and selling practices, partnerships, &c., details on which the average professional man, through lack of business training, is commonly in sore need of guidance. If we have any fault with the book, it is that these objects which it admirably fulfills are not clearly indicated in its principal title.

ANDERSON ON DISEASES OF THE SKIN. (b)

THE second edition of this important work is considerably larger than the original volume. It contains a number of articles specially contributed, as, for example, one by Prof. Unna on Eczema seborrhoicum. The text is illustrated by numerous illustrations and by several well-executed chromo-lithographs. It deals systematically with diseases of the skin, a subject which has of late years attained considerable importance, and is firmly dovetailed into the literature not only of general medicine, but also of other highly-developed specialties. There is no need to discuss exhaustively the contents of the present volume. The author has presented a general view of the subject, and has incorporated the results of his own wide experience. Indeed, the individuality of the Scotch methods and teaching is traceable throughout these pages. As a work of reference the book might perhaps be made more valuable by condensing some parts and enlarging others. The interesting condition of Plica Polonica, for instance, deserves more than a couple of lines. Again, we fail to find any mention of the important group of associated symptoms known as Raynaud's Disease. The author has wisely placed a description of various rare dermatoses to an appendix. The book is well mounted, and should be on the shelves of every practitioner of medicine who is interested in dermatology.

STOCKEN'S DENTAL MATERIA MEDICA. (c)

THIS little book has been in earlier editions favourably reviewed in the MEDICAL PRESS AND CIRCULAR, and calls for little notice now. It probably contains enough information on the subject for the practice of dentistry in which the role of materia medica has a very small place indeed. It is the salutary rule among dentists, including those medically qualified never to prescribe other than strictly local medication. Dentists need practically a knowledge merely of the properties and uses of such drugs as are employed in local applications within and without the teeth, or in the cavity of the mouth, as antiseptic, or other forms of lotions and gargles. This knowledge may be acquired from Messrs. Stocken's book.

(b) "Diseases of the Skin." By T. McCall Anderson, M.D., Professor of Clinical Medicine, Glasgow. 2nd Edition. London: Chas. Griffin & Co.

(c) "Dental Materia Medica and Therapeutics." By J. Stocken, L.D.S. Revised by Leslie S. Stocken, L.R.C.P. and J. O. Butcher, L.D.S., &c. Fourth Edition. London: Lewis, 1895.

New Articles.

ELASTIC CLOTH BANDAGES AND BELTS.

SOME time since we received from the Kieringill's Patent Hygienic and Elastic Cloth Syndicate, Limited, samples of materials for underclothing and elastic belts. We have taken advantage of the interval to put the latter to a practical test, and we are now enabled to speak from experience. The materials comprise ribbed and unribbed cloths, the former being lighter in texture and better adapted for summer use or in hot climates. These cloths can be made up into vests or used in the shape of chest protectors, belts, and the like. They have a soft velvety surface, are extremely elastic, and their texture allows of free cutaneous ventilation, while securing adequate warmth; and, in addition, garments and other articles made thereof can be washed with soap in hot water without detriment to their structure or elasticity. In the form of bandages the cloth affords a uniform and comfortable mechanical support, and its porosity, by facilitating perspiration, obviates the disagreeable sensations associated with the use of ordinary elastic bandages, than which moreover it is cheaper, and it can be efficiently cleaned when required.

Belts made of this material, whether for men or women, are ideally comfortable, and such belts are incomparably superior to similar articles made of the materials usually employed. Those submitted to us were neatly made and finished off in the most workmanlike manner. Their elasticity does not appear to have suffered appreciably even after two washings, and we cannot imagine anyone who has given these a trial ever reverting to the old-fashioned appliances.

The materials lend themselves to compressive appliances of every description, and we are promised a lady's corset which will fulfil a long felt want, among lady cyclists. They are intended to be worn next to the skin, for which their softness of texture and pliability admirably adapt them. The elasticity, moreover, can be increased or diminished in the course of manufacture according to the purpose for which the particular cloth is to be used.

THE "ALLENBURYS" BABY FEEDER.

THIS, the most modern form of the feeding-bottle dear to our infancy, represents a period of evolution extending over many years, during which the ingenuity of inventors has been ransacked in the endeavour to obviate the inconvenience and the dangers of the original feeding-bottle. The "Allenburys" feeder consists of simply a bottle, a valve, and a teat. The bottle, which is graduated to show the amount of fluid introduced, has an opening at both ends,

and it can be thoroughly and easily cleaned by running water through it from a tap. *Verb. sap.* The teat, being of pure rubber, can be turned inside out, thus rendering perfect cleansing possible. The valve stopper has a slit, which allows air to enter as the fluid is withdrawn, and the flow can be regulated by modifying the dimensions of the slit. Verily, the baby of the present day has much to be thankful

for, because, if some mothers still wantonly renounce the pleasurable duty of suckling their offspring, they have, as an alternative, a feeding-bottle which, with ordinary care, is incapable of harbouring the germs of

decomposition, thus averting the colic which past generations of handfed babies have had to grin and bear.

Medical News.

Society for the Relief of Widows and Orphans of Medical Men.

A QUARTERLY court of the Directors of this Society was held January 8th, Dr. Pollock in the Chair. Three new members were elected, and the deaths of five reported. There were no fresh applications for grants. It was resolved that a sum of £1,162 be distributed among the 51 widows, the 8 orphans, and the 4 orphans on the Copeland Fund. The expenses of the quarter were £76. The Christmas present, £452, had been given on December 20th. A further sum of £500 had been received from the executors of Miss Parpus, making in all £3,000.

British Medical Benevolent Fund.

THE Annual General Meeting of subscribers to this fund was held on Tuesday, January 14th, at the residence of the Treasurer. The chair was taken by Mr. J. T. Mould, F.R.C.S., Vice-president, in the absence of Sir James Paget, Bart., President, unavoidably prevented from presiding. Amongst the subscribers present were Drs. Sidney Phillips, Bright, Baines, Felce, Bowles, Holman, and Lowe, and Messrs. Parker Young, Page Kiallmark, Roche Lynch, Byam, Morgan, and Howard Marsh; the Treasurer, Sir Wm. Broadbent, Bart.; and the Honorary Secretaries, Dr. Samuel West (finance) and Mr. Edward East (cases). The financial statement was submitted and the report of the Committee read, and from them it appeared that subscriptions, £991 8s., and donations, £700 18s. 8d., together, £1,692 3s. 8d. had been received, the income from investments amounting to £2,333. £1,548 had been distributed in grants, and 107 annuitants had received £2,114 6s. 8d. The distribution had been effected mainly through the agency of the Cheque Bank in monthly instalments, a mode found by the Committee exceedingly advantageous. Eighteen new annuitants had been elected to supply vacancies caused by death, and grants had been made to 158 applicants, the total number of applications received being 212. Three legacies had been received during the year—£500 from the estate of the late T. M. Stone, Esq., £45 from that of Miss Wallace, and £300 from the late Miss Brigstocke. During the year the trustees had asked to be relieved from the responsibility which they had borne for so long, and had resigned their office. Their resignation was received by the Committee with regret and an expression of thanks for their services in that capacity. Sir William Broadbent, Mr. John H. Morgan, and Dr. Samuel West had accepted office in their place. Several changes in the useful office of Hon. Local Secretary had taken place. Dr. Markham Skerritt had been succeeded by Dr. Michell Clarke, at Bristol. Dr. Duncan succeeded Dr. Miller at Dundee, and new Secretaries had been appointed for Tottenham, Hampstead, and Kilburn, viz., Dr. G. A. Wateon, J. W. Pilcher, Esq., and Dr. Thurton, and Mrs. E. E. Palmer had accepted the post of Lady Collector at Norwich. Dr. Baxter Forman, Dr. Marmaduke Prickett, and Mr. Edward East joined the Committee, and Sir Henry Acland, Sir Edward Sievking, and Mr. Herbert Page were appointed Vice-Presidents. Mr. Edward East resigned his appointment as Secretary for cases, and received the thanks of the meeting for his long services, and is succeeded by Mr. Joseph White, 6 Southwell Gardens, S. W. Votes of thanks were passed by acclamation to the Treasurer, Secretaries, Auditors, and to the Medical Press, and Mr. Mould was thanked for his services to the fund and for his conduct in the chair.

The British Gynaecological Society.

The following is the result of the ballot for officers of the above Society:—

Honorary President: R. Barnes, M.D., F.R.C.P. (London). President: Clement Godson, M.D., M.R.C.P. (London). Vice-Presidents: C. H. Bennett, M.D.

(London), Professor J. W. Byers, M.D. (Belfast), H. Macnaughton-Jones, M.D. (London), Leith Napier, M.D. (London), A. A. Raach, M.D. (London), Professor W. L. Reid, M.D. (Glasgow), Professor A. W. Mayo Robson, F.R.C.S. (Leeds), C. H. F. Routh, M.D., M.R.C.P. (London), J. W. Taylor, F.R.C.S. (Birmingham), Professor J. Wallace, M.D. (Liverpool), W. Gill Wylie, M.D. (New York). Treasurer: J. A. Mansell-Moullin, M.D. (London). Librarian: George Granville Bantock, M.D. (London). Council: Dudley Buxton, M.D. (London), T. Kilner Clarke, F.R.C.S. (Huddersfield), E. Temison Collins, F.R.C.S. (Cardiff), W. Dingley, M.R.C.S. (London), T. B. Gimsdale, M.B. (Liverpool), F. N. Haultain, M.D., F.R.C.P. Ed. (Edinburgh), W. Balls Headley, M.D., F.R.C.P. (Melbourne), P. L. Hebert, M.D. (London), R. A. Hodgson, M.R.C.S. (London), F. Bowdeman Jessett, F.R.C.S. (London), Lewis Jones, M.D. (London), J. Macpherson Lawrie, M.D. (Weymouth), Henry Lewis, M.D. (Folkestone), R. Marsden Low, M.B. (London), J. J. Macan, M.D. (London), H. Michie, M.B., (Nottingham), J. R. Morison, F.R.C.S. (Newcastle), James Oliver, M.D. (London), H. W. F. Powell, F.R.C.S. Ed. (London), T. Savage, M.D., F.R.C.S. (Birmingham), Professor A. J. Smith, M.D. (Dublin), S. Sunderland, M.D. (London), W. Travers, M.D., F.R.C.S. (London), A. Wallace, M.D. (London). Editor of Journal: Leith Napier, M.D., F.R.S. Ed. Honorary Secretaries: F. F. Schacht, M.D. (London), John Shaw, M.D. (London).

The Harveian Society.

THE following gentlemen were elected to office at the last meeting of this Society:—

President: Mr. J. Knowsley Thornton, M.B., C.M. Vice-Presidents: Dr. W. Hill, Dr. E. Clifford Beale, Mr. E. W. Roughton, Dr. Lamb. Treasurer: Mr. H. Cripps Lawrence. Council: Sir John Williams, Bart., Mr. R. S. Armstrong, Mr. E. Bartlett, Mr. Peyton Beale, Dr. Boxall, Mr. Henry Davis, Mr. George Eastes, Dr. L. Guthrie, Mr. F. W. Hazel, Mr. S. Harlbut, Mr. Henry Juler, Dr. J. E. Squire. Hon. Secretaries: Dr. Cagney, Dr. F. W. Cock.

Society of Members of the Royal College of Surgeons of England.

A MEETING of the Executive Committee of this Society was held on the 16th inst., at which the following resolution was carried unanimously, and ordered to be communicated to the medical journals:—"The Executive Committee of the Society M.R.C.S. desires to thank the Fellows most heartily for their recent vote affirming the principle of the direct representation of Members upon the Council, and the Committee hope that this vote will mark the commencement of a new era, in which the Fellows and Members will work together for the good of the College.

Compulsory Notification Fees for Ireland.

WE note that the Local Government Board for Ireland has intimated to the Lurgan Town Commissioners that they are at liberty to pay to the medical officer of the workhouse the munificent fee of one shilling for notifying to the medical officer of health any case of infectious disease which occurs in the workhouse. It appears that the Act of Parliament which fixes the fee payable to a private practitioner at 2s. 6d. does not allow more than 1s. for a public medical officer.

The Health of Ireland.

THE last quarter of the year which has just closed is reported by the Registrar-General to have been exceptionally healthy, the death-rate for Dublin being for that period 23.9, or 2.9 below the average. This ratio compares with 18.0 for London, 19.2 for Glasgow, and 17.1 for Edinburgh for the same quarter. The improved health of the city has been due to the exceptional small number of zymotic deaths, which numbered 36 per cent. below average. There was a rapid declension in the frequency of small pox. The ratio for the 15 towns outside Dublin was 22.8 per 1,000 of population, measles having been severe in Belfast and scarlatina in other towns.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

LOCAL REPORTS AND NEWS—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

GENERAL PRACTITIONER (Leeds).—A good English artificial eye will last about twelve months. Although glass-eyes of foreign manufacture are cheaper, they will not stand wear as long as English made eyes. It is the solvent action of the tears upon the glass that causes glass-eyes to become rough and unsuitable for further use. A large manufacturer has stated that about 50,000 of these appliances are used up annually.

BE CAREFUL OF SODA WATER!

MARK TWAIN has been giving a lecture on soda water. He said that he could not recommend it as a steady drink. After drinking thirty-eight bottles he found himself full of gas and as tight as a balloon. He had only one article of clothing left that he could wear, and that was his umbrella.

MR. C. C. L.—The matter shall be carefully considered, but we think you have taken an extreme view of your neighbour's position.

DR. SCHWARTZ, (Constantinople).—Paper received.

M.R.C.S., L.R.C.P. (Crewkerne).—Pure cow's milk should have a specific gravity of 1.030, and should yield from ten to fourteen volumes per cent. of cream, and never less than three per cent. by weight. The normal amount of water should be about eighty-seven per cent.

THE ARMY MEDICAL SERVICE.

A COMPETITIVE examination for seventeen commissions in the Army Medical Staff will be held on the 7th February and following days. Particulars thereof will be found in our advertisement columns.

DR. DOCKRELL.—The paper is a fairly wide one, well suited to test the candidate's knowledge.

A MEDICAL CLUB FOR LIVERPOOL.

A LIMITED company has been formed in Liverpool, with a capital of £1,000, for the purpose of starting a medical club. There are fifteen directors, all medical practitioners in the city.

A MEMBER.—We do not intend to take sides in the contention; it is a purely commercial question between opposing interests and we think it a mistake to have raised it in the first instance.

MEDICAL DEFENCE INSURANCE.

THE defence of the profession in respect of its "character and financial interests" has been taken up by a company recently formed in London with a capital of £10,000. It is to combine insurance in its function, but of what nature does not transpire save that it is not to be insurance on life. The first subscriber is a chemist.

DR. MORTIMER has missed the point contended for, if he will re-read the article it will be readily seen.

A QUACK'S LABEL CASE.

WE chronicled in our last number the conviction of John Ferdinand, M.D., U.S.A., who has been for some time in illegal practice. The said individual has felt aggrieved because a legitimate practitioner referred to him as "a damnable liar, a daylight robber, and one of the worst impostors that ever came to London." Of course this was hardly polite language to use even when referring to a quack, and so the matter had to be threshed out at the Sheriff's Court on Friday last. Ferdinand sought £2,000 damages, and received 6s.

DR. FLEMING (Liverpool).—No information upon the subject has so far reached us. If our correspondent will forward us the papers we will be glad to comply with his request.

SOCIETY OF ANESTHETISTS.

THE secretary of this society asks us to point out that Mr. G. Hewlett Bailey, President, was in the chair at the meeting reported in our columns in the 8th inst., not Mr. F. Woodhouse Braine, whose term of office has expired.

F.R.C.S.L.—The offices of the General Medical Council are at 299 Oxford Street, London, W.

HINTS TO A CYCLIST.

Do not be stubborn with a balky wheel. If the front wheel gets in a rat going east, and the hind wheel in another going west, dismount and argue the matter standing, unless you are tired and want to lie down by the roadside without making the effort to do so unassisted. Keep your lamp lit when riding at night. The boy who thought he was safe because he had a parlour-match in his pocket came home with a spoke in his wheel which didn't belong there.—*Harpur.*

Meetings of the Societies.

WEDNESDAY, JAN. 22ND.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—5

p.m. Cases by Drs. Stowers, Abraham, Walsh, and others. Dr. Eddowes: Warts of the Feet.
HUNTERIAN SOCIETY.—8 p.m. Clinical Evening. Sir Hugh Beavor: Hemiplegic Tremor. Dr. Fred. J. Smith: (1) Hemianopsia; (2) Motor Aphasia. Mr. Wm. Fettes: Cuticular Diseases for Diagnosis. Dr. J. F. Woods: Cervical Neuralgia treated by Suggestion without Hypnotic Sleep. And other cases.
SOCIETY OF ARTS.—8 p.m. Mr. Frank W. Grierson: Supply of Sea-water to London.

FRIDAY, JAN. 24TH.

CLINICAL SOCIETY OF LONDON.—Dr. A. Wilson: A Girl after Menigitis in Hystero-epileptic state with Dual Existence. Dr. Norman Dalton: Myopathic Muscular Atrophy in an Adult. Mr. J. E. Lunn: Suppuration of the Shoulder-joint in a Man aged sixty-three. Twice Succeeded Excision of the Temporo-maxillary Joint for Arthritis Deformans, Charcot's Disease of Shoulder-joint. Mr. H. Paterson: A Case of Extensive Skin Grafting. Mr. H. B. Robinson: Birth Injury to Upper Extremity of Femur. Mr. C. Mansell Moulin: Impaired Growth of Lower Epiphysis of Tibia consequent on a Strain. Mr. Raymond Johnson: Case of Traumatic Orbital Aneurysm.

Vacancies.

Bootle Borough Hospital.—Senior House Surgeon. Salary £80 per annum, with board, washing, &c. Applications to be addressed "Chairman," Bootle Borough Hospital, Bootle.
Bradford Infirmary.—Dispensary Surgeon. Salary £100 per annum, with board and residence. Applications endorsed "Dispensary Surgeon," before Jan. 27th.
Dorset County Hospital, Dorchester.—House Surgeon. Salary £70, with board and residence. Further particulars of W. E. Groves, Icenway, Dorchester, Clerk to the Committee.
Samaritan Free Hospital for Women and Children, London.—Surgeon to the Out-Department. Applications and testimonials to be sent to the Secretary not later than Feb. 4th.
The Middlesex Hospital Medical School.—Lectureships on Anatomy and Physiology. Applications to the Dean of the Medical School, from whom all further information may be obtained.
Tower Hamlets' Dispensary.—Resident Medical Officer. Salary £120 per annum, furnished rooms, coals gas, and attendance. Applications to the Secretary, Tower Hamlets' White Horse Street, Stepney.

Appointments.

BARKER, G. C., M.A. Camb., M.D. Brux., L.R.C.P. Lond., M.R.C.S. Physician to the Brighton and Bove Dispensary.
GARRAD, F. W., M.B., B.C. Cantab., House Surgeon to the Worsfold and South Warwickshire Hospital, Leamington.
GILES, B. O'H., M.B., Ch.B. Ad., Health Officer to the Wyndham Shire Victoria, Australia.
GREENE, Dr. T., of Green Lawn, Ennis, Assistant Medical Officer to the Ennis District Lunatic Asylum.
HENRY, G. W., L.R.C.P. Lond., M.R.C.S., Medical Officer of Health by the Minehead Urban District Council.
HOLDEN, J. S., M.D. Irel., L.R.C.S. Edin., Medical Officer of Health by the Belcham and Melford Rural District Council.
JUNSTONE, W. E., M.A., M.B., C.M. Edin., House Surgeon to the Darlington Hospital and Dispensary.
MANN, E. P., M.D., D.P.H. Camb., Assistant Medical Officer for Liverpool.
PHILLIPS, J. N., L.R.C.P. Lond., M.R.C.S., Medical Officer of Health for the Cannock Rural Sanitary District.
PORTER, W. S., M.D. Durh., L.R.C.P. Lond., M.R.C.S., Examiner of Lunatics for Shrewsbury.
REID, G. M., M.B., Ch.M. Aberd., Health Officer for the Heytesbury Shire, Victoria, Australia.
STRANGE, A., L.R.C.P. Lond., M.R.C.S., Assistant Medical Officer for the Infirmary of the Whitechapel Union.

Births.

HOWELL.—Jan 13th at Middlesbrough-on-Tees, the wife of R. Edw. Howell, M.B. Edin., M.R.C.S. L.R.C.P., of a daughter.
HUMPHREYS.—Jan. 15th, at 50 Fairholme Road, West Kensington, the wife of Charles Lyle Humphreys, M.D., of a son.
PARR-DUDLEY.—Jan. 15th, at The Grove, Cossington, Leicester, the wife of Arthur D. Parr-Dudley, M.R.C.S., L.R.C.P., of a son.
SANDERS.—Jan 9th, at Châlet St. Vincent, Cannes, the wife of Gordon Sanders, M.B., F.R.C.P. Edin., of a son.
WOOLLETT.—Jan. 16th, at 35 Telford Avenue, Streatham Hill, London, the wife of C. J. Woollett, M.D. Lond., F.R.C.S. Eng., of a daughter.

Marriages.

COATES—FREE AND.—Jan 11th, at the Cathedral, Chichester. William Coates, M.R.C.S., L.R.C.P., Ingleside, Whalley Range, Manchester, to Leonora Stillewail, sixth daughter of the late Frederic John Freeland, of Chichester.
SHAW—LOND.—Jan. 16th, at Hove Parish Church, George Shaw, F.B. Lond., of The Drive, Hove, to Annie Louise, third daughter of C. W. Lord, Esq., of The Drive, late of Acton Hall, Sudbury.

Deaths.

TUPPEN.—Jan. 9th, at Nagasaki, West Cliff Road, W., Bournemouth, Harry Stacey Tuppen, M.A., M.B. Camb., aged 34 years.
WATTS.—Jan. 7th, Robert George Watts, M.A., M.D. St. And., Albion House, Quadrant Road, Canonbury, aged 62 years.

Original Communications.

A SERIES OF CASES

OF

INTESTINAL RESECTION.

BY HERBERT W. ALLINGHAM, F.R.C.S.,

Surgeon to the Great Northern Hospital, Assistant Surgeon to St. George's Hospital.

IN this paper will be recorded all the cases in which I have resected portions of the intestines, although the results, as will be seen, are not as satisfactory as one could wish; still, I feel, that only by narrating both successful and unsuccessful cases is it possible to arrive at any definite conclusion as to the correct way of treating cases of this kind under the various conditions which they may present. After narrating the cases, I shall discuss them and endeavour to indicate the procedure which I shall adopt in the future.

CASE I. Resection of Stricture of the Sigmoid Flexure.—(A full report of this case appeared in the *Clinical Society's Transactions* for 1893.) In October, 1892, I saw, in consultation with Dr. William Neale, Mrs. S., *æt.* 54. The patient had always been subject to constipation, especially during the last year. For six weeks the bowels had ceased to act, and for a month before that they had acted with difficulty. Purgatives and enemata only caused the occasional passage of a little flatus and one liquid motion. She had never passed blood or slime.

When we saw her she had vomited for some days. The abdomen was greatly distended. There was no growth to be felt, and an examination *per rectum* revealed nothing.

As the length of time of the obstruction seemed to indicate that the stricture was low down in the large intestine, it was agreed to make an incision in the left inguinal region for the purpose of examining the colon in opening it, if it was distended.

I made an incision three inches long, about an inch inside the left antero-superior spine of the ilium, opened the peritoneal cavity, and found that the large intestine was greatly distended. The gut was brought up to the inguinal opening, and when the hand was inserted into the peritoneal cavity a mass was felt in Douglas's pouch. This was brought to the inguinal opening, and was found to be a malignant growth in the sigmoid flexure. This growth and about fourteen inches of the gut were pulled through the inguinal incision, the parietal peritoneum was stitched to the skin all around the abdominal incision, and the mass of sigmoid flexure and growth was fixed outside the belly wall. The gut was then opened above the cancerous mass, but, as no *feces* passed away, the intestine had to be opened below the growth, and *feces* were at once discharged. A Paul's tube was inserted, and was kept there for three days.

Ten days after the operation the mass of gut and the growth were clamped and cut away, the mass removed weighing ten and a half ounces. In a month's time the patient was quite recovered, the bowels acting daily from the inguinal opening. I have seen this patient lately, and advised that the artificial anus be

resected, and a cure effected. She said that she was so comfortable with the colotomy that she did not feel inclined to run any further risk.

CASE II. Resection of Stricture of Descending Colon.—(This case was published in full in the *Medical Society's Transactions* for 1894.) William C., *æt.* 30, was admitted into the Great Northern Hospital, on January 9th, 1893. No family history of cancer or phthisis—never had typhoid or resided in any foreign parts. For the last two years had suffered from constipation, and about six months prior to this attack had had abdominal obstruction lasting for about a week, relieved by purgatives and enemata.

For the last ten days before admission he had not had an action of the bowels. On admission the abdomen was greatly distended, no tumour to be felt; nothing had passed by the rectum even after repeated enemata, no rectal stricture. On January 11th, the abdomen was opened in the middle line below the umbilicus, and the cæcum and small intestines were found to be enormously distended. The intestines were so stretched that I was afraid very carefully to explore the abdominal cavity for fear of bursting the guts. Accordingly, the cæcum was well drawn into the wound in the belly-wall, opened, and a quantity of *fecal* matter came away. When more than two quarts of liquid *feces* had escaped, the opening in the cæcum was closed with pressure forceps. The cæcum was then thoroughly washed and returned into the abdomen, and the part of the cæcum around the clip on the opening was carefully sutured to the edges of the abdominal wound about its lower part.

The next day, as the cæcum seemed well glued up to the belly-wall and the cavity thoroughly blocked off by lymph, the clip on the opening in the cæcum was removed. From this time the patient made an uninterrupted recovery, the bowels acting daily by the artificial anus, nothing whatever passing by the rectum. On May 29th he returned to the hospital greatly improved in health; he was fat and looking well. The bowels acted daily by the artificial anus, in fact the *feces* were constantly running away.

On May 31st I made an incision five inches long along the left *linea semilunaris*, meaning to hunt carefully through the sigmoid flexure and all the colon to find the cause of the obstruction and remove it if possible. I introduced my hand, and commenced by passing the sigmoid flexure through my fingers. This being normal, I continued my search up the descending colon, and about its centre found a hard tight stricture. The gut above and below the stricture was secured by india-rubber tubes passed through the mesentery. A large piece of the gut and the stricture between the tubes (about four inches in length) was then excised. The proximal and distal openings in the gut were carefully joined over a Mayo Robson's bobbin, the mucous membrane of the intestines being first sutured together as described by Mayo Robson by silk sutures, and lastly, the serous surfaces of the gut united with Lembert's sutures.

The patient recovered without interruption from this resection, and on June 14th I closed the opening in the cæcum.

On the 21st of June the wound in the cæcum was healed, the bowels acting by the rectum.

The patient remained in perfect health until Sept. 18th, when he returned to the hospital complaining of pain in the abdomen and of being sick. The abdomen was distended. As after several doses of castor oil and injections, he was no better, on September 24th, I determined to explore again the part where the stricture had been resected, thinking that perhaps the gut had contracted at the seat of resection. Accordingly, an incision was made parallel to the one about the left linea semilunaris, but a little inside it. When the abdomen was opened, it was found that the peritoneum was studded with hard nodules, and that there were masses in the walls of the small intestines, and great thickening and nodulation of the mesentery generally. The part where the resection was done was perfect—no stricture or contraction whatever. The patient recovered from operation, and stayed in the hospital until October 13th. He was taken to his home at Southampton, and was placed under the care of Dr. Robert Walch, to whom I am greatly indebted for the post-mortem examination and the specimens. The patient died on November 9th, ten months after the first operation.

CASE III. Resection of Inguinal Artificial Anus.—(This case was published in full in the *Lancet*, June 23rd, 1894.) A woman, *æt.* 48, came under the care of my colleague, Dr. C. E. Beevor, at the Great Northern Hospital, on March, 8th, 1894. About three months before she was suddenly seized with pains in the abdomen after a cup of tea, and was treated for dyspepsia. Ever since that attack she had had violent abdominal pains from time to time. A fortnight ago, she noticed her abdomen swollen. She had been sick several times the last fortnight, and had constant griping pains about the abdomen. On her admission to hospital the abdomen was found to be considerably distended, principally over the lower part. Deep palpation excited peristaltic action, and the distended coils stood out very distinctly through the abdominal wall. Per rectum and vaginam, nothing abnormal was to be felt. On March 10th, at the request of Dr. Beevor, I saw her, and, concluding from the history that there was some obstruction in the large intestine, decided to open the abdomen in the left inguinal region. This I did, and found the sigmoid flexure greatly distended. Before, however, fixing it to the abdominal wall and opening it, I determined to explore the abdomen with the hand, in order to (if possible) find out the nature of the stricture. Accordingly the inguinal incision was slightly enlarged, and then the hand was passed into the abdomen, the pelvis being thoroughly explored. To my surprise, no growth or band could be found about the intestine in the pelvis. Accordingly the search was pursued along the descending and transverse colon; there again, nothing was found. The sigmoid flexure being so distended, I thought I might have overlooked some band in the pelvis, or that the distension and symptoms were due to an over-distended and so paralysed gut. Presuming this to be the case, the large gut was fixed to the incision and opened. A Paul's tube was inserted into the gut. The next morning, March 11th, nothing had passed through the Paul's tube. Accordingly, I decided to open the abdomen on the right side over the cæcum. This was done by a vertical incision about the right linea semilunaris. The cæcum was found to be greatly distended. I passed my hand into the abdomen and explored the cæcum and the ascending and transverse colon, but was unable to find any cause for the obstruction. Here, again, as on the left side, the large gut was found to be distended. This being the case, I determined not to be misled again by the distended appearance of the large gut, so resolved to investigate the small intestine. The small intestine was traced upwards, and at about the juncture of the jejunum with the ileum, were found two coils of gut firmly adherent to one another to the extent of

about two inches. The adhesions were firm and old, and it was with great difficulty that one loop was separated from the other. When the coils were separated, in one was found a stricture about half an inch broad at the part where it had been adherent to the other coil. This stricture was treated by enteroplasty. The patient recovered, and all the motions passed by the inguinal colotomy opening. The spur about the colotomy opening, being well formed, prevented any motion passing beyond it, and so on to the rectum. The spur about the opening began to get more prominent, in spite of an attempt to reduce it by pressure with the finger daily. This being the case, it appeared to me useless to attempt any plastic operation to close the artificial anus. On April 16th the patient was put under chloroform. The skin around the artificial anus was divided and the peritoneum opened, and the gut pulled well out of the abdomen. The sigmoid flexure having a fairly long mesentery, it was easily drawn out of the abdomen. Two drainage-tubes were passed through the mesentery and secured with clip-forceps around the gut, about three inches above and below the artificial anus. Above four inches of the gut, with the anal opening, were then cut away. Then a Mayo Robson's bobbin was inserted between the ends of the divided gut, and the gut united over it in the usual manner. On the 27th some glutinous material was seen in the motions (bobbin?). She was seen again lately (July, 1895), and she was quite well in every respect.

CASE IV. Resection of Stricture of Sigmoid Flexure.—I saw, with Dr. Tyson, a Mr. G., *æt.* 67, who gave the following history. He had always suffered from constipation, but for the last six months his trouble had become much worse, the bowels never acting without strong purgatives. It was not uncommon for him to go a fortnight or longer without an action. There was no history of cancer. He had lost flesh and at times suffered from severe colic pains. Upon examination, the abdomen was rather distended, having a doughy feel. There was dulness along the course of the large intestine, and about the sigmoid flexure there was a hardish mass, rather tender to the touch. An examination per rectum revealed nothing.

An inspection of *fæces* passed after a strong purge, showed them to be liquid and offensive, but not containing blood or slime. After having him under observation for about ten days, and trying the effect of purgatives, belladonna, &c., without any result, on May 15th, 1894, I opened the abdomen on the left side, the centre of the incision being about an inch from the left anterior superior spine of the ilium. On opening the abdomen there was found at the upper part of the sigmoid flexure a hard, annular, malignant stricture. The intestines above the stricture were distended with doughy *fæces*. As the mesentery appeared to be free of malignant disease, and there was no evidence of enlargement of glands about the abdomen, I decided to resect the stricture. Drainage-tubes were passed through the mesentery, so as to constrict the intestine above and below the stricture, which was then removed. The ends of the gut were then united by Mounsell's method. The gut was washed and returned into the abdomen, and the abdominal wound was closed in the usual way. There was no sickness; the temperature that night was 102°; the patient slept, and he passed water; the pulse was 88; the abdomen was not distended or tender.

On May 16th he had had a good night. The pulse was 84; the tongue was moist; the temperature 99°; there was no pain whatever, and the facial aspect was good.

On May 17th, in the morning, the report was that he had had a good night, the temperature was 99°, there was no pain, the pulse was 88, the tongue was moist, there was no tenderness or distension about the abdomen: at 10³⁰ a.m. the patient said that he felt

rumbling about his stomach, and described a sudden burst of wind, accompanied with great pain in the abdomen. The pulse became rapid, the aspect changed, the abdomen soon became tympanitic and tender, and he died late that night. Evidently some of the stitches gave way.

CASE V. Resection of Stricture of Ascending Colon.—John R., *æt.* 66, was admitted into the Great Northern Hospital. Three months previously he had diarrhoea and pains in the abdomen. The pain had continued more or less ever since. For the last fourteen days he had been constipated, and the pain was growing much worse.

On admission the abdomen was distended and tense, with marked peristaltic contractions and great griping abdominal pain.

As I thought from the history of diarrhoea that the stricture might be low down in the large intestine, on May 23rd, 1894, an incision was made in the left inguinal region. On introducing the hand into the abdomen, the sigmoid flexure, descending and transverse colons were found to be empty. A hard mass was felt in the ascending colon. Accordingly the left inguinal abdominal opening was closed, the patient was turned over on to his left side, and an incision was made for right lumbar colotomy. The ascending colon was found and drawn out of the wound, and towards its upper part was a hard, localised growth. This was drawn out of the wound, the bowel clamped above and below, and the growth resected. The distal end of the colon was closed and stitched to the end of the wound. The proximal end was left open, and a Paul's tube was fixed in it. The bowel was stitched to the end of the wound.

The patient made an uninterrupted recovery, the bowels acting daily from the lumbar opening. On June 20th I opened the abdomen in the middle line and anastomosed the transverse colon to the ileum about 13 inches from the cæcum with a Mayo Robson's bobbin. By thus anastomosing the small intestine to the transverse colon I hoped that I should, at a later date, be able to close the right lumbar opening. The patient recovered from this operation, some of the faeces passing from the lumbar opening, others passing down to the rectum.

On September 26th an endeavour was made to close the colotomy opening, an incision being made round the colotomy opening, including the edge of the skin, about $\frac{1}{2}$ inch in breadth, and the gut was freed all round with some difficulty, and was well drawn out of the lumbar wound. The end of the gut, including the skin, was cut off. The end of the gut was next firmly sutured up, and its peritoneal surfaces were brought into contact by Lembert's sutures. The skin edges were then united, the blind end of the gut being left near the surface, so that if leaking took place the faeces might find their way outside the belly.

On October 2nd I was sorry to notice that the lumbar wound had broken down and that some faeces were leaking. This leaking continued, some of the faeces escaping by this opening, and others passing by the rectum.

He was kept in the hospital till January 25th, 1895. The opening in the lumbar region had contracted up to quite a small fistula, but some faeces still escaped by that orifice. He was then discharged, his general health being good. I have not heard of him since.

(To be concluded in our next.)

THE Islington Vestry has just caused two buildings to be erected in the parish in which to accommodate, free of charge, families among whom dangerous infectious disease has appeared, and who have been compelled to leave their dwellings for the purpose of enabling the sanitary authority to disinfect the same.

Lectures

ON

THE DIAGNOSIS OF INSANITY.

By THEO. B. HYSLOP, M.D.,

Lecturer on Mental Diseases to St. Mary's Hospital Medical School,
Assistant Physician to Bethlem Royal Hospital.

LECTURE V.

Insanity in Children.—Attacks of insanity in children are sometimes caused by sudden changes in temperature, or by over-exposure to the sun. In children, as in adults, the neuroses following sunstroke are somewhat similar to, and have much in common with, the traumatic neuroses. The chief clinical features in children whose mental perversions had been attributed to sunstroke are:—(a) absence of bodily infirmity; (b) full development and comparatively normal dimensions of the muscular and osseous systems (including the shape of the head, jaws, and teeth); (c) special affections of speech, either of a temporary character immediately following the attack, or as a continued impairment or failure in development of the faculty; (d) frequent occurrence of fits immediately after the attacks, lasting for a short period, but not continued through life; (e) defective or perverted moral states, as seen in various grades, from mere disobedience, to propensities peculiar, dangerous, or even homicidal, and sometimes, though rarely, habits of a degraded nature; (f) limited mental capacity, with failure to improve much by the ordinary educational methods; (g) attachments, antipathies, and peculiarities, which are in most cases retained through life; also an absolute inability to compete with their fellow beings, or to look after their own interests.

Head injuries, affections of the peripheral nerves, diseases of the throat, nose, or ears, digestive troubles, and the presence of intestinal worms, also tend to act directly or indirectly on the nerve centres and cause insanity. Of febrile diseases, scarlet, typhoid, and rheumatic fevers, and measles, are apt to be attended by grave mental disturbances. Whether the psychological disorders are the direct result of the noxious influence of the specific disease-germs, or whether only indirectly owing to nutritive disturbance, is at present doubtful. Spitzka believes in the former theory on the grounds that (a) analogous affections, such as the progressive sopor following diphtheria, are accompanied by evidences of microparasitic invasion of the nerve-centres; (b) the psychological results of post-febrile insanity are different from those resulting from simple nutritive disturbance; (c) the organic nervous diseases exceptionally following essential and exanthematous fevers are usually multilocular, and indicate the operation of an irritant distinct from a mere deprivation of nutriment.

At puberty, individuals of both sexes are prone to break down mentally, and more especially so if there is an inherited tendency. The majority of cases are of the maniacal and exalted types. Another feature is the tendency to remission and periodic recurrence of the symptoms. Such patients seldom become actually delirious. The relation of menstrual derangements to the mental state is inconstant. Usually there is impoverishment of the blood in adolescent and pubescent insanity.

Puerperal Insanity.—The puerperal period is fraught with danger to individuals who are predisposed to neuroses. The causes of puerperal insanity may be grouped as follows:—

(1) Predisposing:

(a) Heredity.

(b) Expectancy (a woman who has had a previous attack of puerperal insanity may dwell on that fact and predispose herself to another attack).

- (2) Exciting :
- (a) Physical causes, such as debility, consequent on labour, or prolonged lactation.
 - (b) Suppression of the lochia or milk, with consequent blood poisoning.
 - (c) Subinvolution of the uterus, metrorrhagia, or leucorrhœa which may act as exciting factors.

I agree with Dr. Savage in believing that there is no well-defined form of insanity deserving the name of puerperal insanity. Mental disorders may arise at any time from the earliest stages of pregnancy to late periods of weaning. The condition of the patient at the time of the onset of the mental symptoms has much to do with the nature of the case. Thus, a patient who is undergoing a natural pregnancy or labour, but who is subjected to some sudden shock or worry, is, in my opinion, more likely to suffer from an acute mental disturbance of a maniacal nature. A patient, on the other hand, exhausted by the drain on her system, subjected to many worries and cares, is more likely to be melancholic. A diagnosis of the true nature of the case can only be made by taking into account all the possible factors of causation. An acute onset due to outside existing factors is more favourable as regards the length of the illness, than a gradual onset due to physical exhaustion. In the former state the patient frequently recovers within a few months, whereas in the latter the period may extend to a year or even more. Some of these patients do not entirely recover in asylums, and it is only after returning to their homes that they gradually regain their mental power. Some cases do not recover. The prognosis is influenced by several considerations. The puerperal state may be the means of determining an incurable state to which the individual was predisposed by heredity. It must be remembered, however, that hereditary predisposition, although unfavourable to permanent recovery does not necessarily imply that the patient will not recover from the first attack. As a rule, puerperal insanity is very curable. Perversions of the moral character, and impulsive tendencies, are far from being symptoms of incurability. Alternations of excitement and depression are usually unfavourable signs. Remissions and relapses are common, but the patients sometimes ultimately recover from them. Perhaps the most unfavourable symptoms are the development of delusions of persecution, or of grandeur, the systematic growth of hallucinations, especially those of hearing, the recovery of physical health, unaccompanied by improvement of the mental condition.

There is no uniform rule with regard to the return of the menses. Some melancholiacs pass into a condition of mania on the return of menstruation; others pass into dementia, in spite of the restoration of physical health. Restoration of sleep is a good sign, whilst prolonged insomnia is unfavourable. The terminations of puerperal insanity are therefore either (a) complete and early recovery, (b) prolonged and gradual recovery, (c) permanent partial weak-mindedness, (d) chronic delusional insanity, (e) dementia, or (f) death, due to the acuteness of the attack or to intercurrent affections.

The *menopause* is an important epoch in the life of women. The factors causing insanity at this period may be grouped as follows:—(1) Predisposing: (a) Heredity—the actual attack of insanity being determined by causes operating at the time; (b) previous attacks of insanity; (c) the physical and psychical transformations associated with the termination of the reproductive period. (2) Exciting causes, as (a) worry or anxiety, (b) accidental circumstances, such as shock, bodily disease, &c.; (c) sudden cessation of the menstruation, producing physical ill-health. In some cases, it must be remembered, the physical change

and the mental affection may be merely coincidental, and not necessarily causal.

The mental condition at the climacterium is usually one of subacute melancholia or mild mania. Many patients recover with the restitution of their physical health; others however, do not recover, but pass into a chronic delusional state, usually with ideas of persecution. When the condition is one of mild mania or subacute melancholia the prognosis is generally favourable. Illusions or hallucinations of any of the senses, and more especially of common sensation, together with a tendency to form delusions as to persecution, form unfavourable indications as to curability.

Senile Insanity.—Abnormal mental manifestations in old age may arise in connection with slowly developing constitutional changes, or with atheromatous degeneration of the vascular system, and an increasing atrophy of all the organs. The symptoms may be functional or organic. The functional disorders may resemble the affections of earlier life in every particular. Hypochondriasis, melancholia, mania, and delusional states are common types of disorder in the senile person, and these affections may be recovered from, just as in youth. Affections associated with organic senile degeneration are usually progressive in nature and indicate arterial degeneration and disintegration of the nerve structures. Interstitial change or gross cerebral disease such as occurs in chronic cerebral atrophy with sclerosis, hæmorrhage, or softening from thrombi, may be attended by an attack of melancholia, mania, convulsions, epilepsy, or dementia. The condition of the memory in senile cases is of great importance. In progressive degeneration the memory undergoes retrogression, and recent events tend to become obliterated. I have seen several cases of senile mania in which many years of the individuals' memories have been entirely obliterated. One patient, aged 79, maintained that his age was 35, and failed to recollect events of more recent years. Another patient, aged 67, maintained that he could remember being a child, but that he never grew up, in fact, he still regarded himself as a child in spite of a grey beard and other indications of his advanced age. Another patient maintained that he was still in Ireland, and that he had never been on the sea in his life. He had, in reality, crossed over to England some fifteen years previously, but had forgotten the circumstance; he also failed to recall events since that period. We are all acquainted with the features of old age, and know how the aged person delights in recalling the events of his youth. He dwells in the past, and entertains those around him with anecdotes of childhood. He also fails to remember that he had recently told the same story, consequently the tendency to repetition is characteristic. Some senile persons are so solicitous as to the welfare of their stomach and bowels that their minds constantly dwell upon their own digestive faculties. One sees the more characteristic manifestations of this type in asylums, and associated with this tendency is the readiness to become hypochondriacal and hypersensitive as to the functions of the digestive tract.

The main features of senility, therefore, tend to group themselves into three main types, which have been termed respectively, *dotage*, *anecdote*, and *table d'hôte*-age. Before leaving the subject of senility, mention must be made of a symptom which is one of vital importance, namely, the occurrence of sexual excess as an indication of brain decay. The victims of senile brain decay are not uncommonly the victims also of morbid sexual propensities. Thus, some men, who have held their passions well under control during earlier life, become sexually erotic, and indulge their morbid propensities to the fullest extent. Not a few of such unfortunate beings bring discredit and shame

upon a hitherto blameless life, and involve themselves in troubles which end in ruin and disgrace. The early recognition of such morbid tendencies ought to be the duty of every medical man, and were more careful attention given to this subject, I feel sure that the mind of society would not suffer in the future so much as it has done in the past from the narration of revolting sexual details.

In studying the previous history of the insane, it is essential that we should take some account of the previous illnesses of the patients. I propose, therefore, to deal with such affections as fevers, malaria, rheumatism, gout, anæmia, syphilis, tuberculosis, cancer, anæmia, chlorosis, diabetes, goitre, &c., and when considering these subjects it will readily be seen how they may modify the diagnosis and prognosis in cases of insanity in which they have been factors of causation.

Febrile Affections are not uncommonly complicated with, or followed by, mental disturbances. The mental disorder may appear as the earliest symptom; more commonly, however, it appears during a later stage of the fever, especially during convalescence. Bristowe and Murchison have recorded cases in which acute mania occurred as the earliest symptom of typhoid fever. There has mentioned acute mania as occurring before an attack of pneumonia, and Greenfield the occurrence of melancholia followed by general excitement with hallucinations of sight and hearing appearing and subsiding *pari passu* with an attack of pneumonia. The symptomatic delirium or febrile delirium is often difficult to distinguish from true insanity, and almost any of the affective states of mental disorder may be completely simulated in febrile delirium. The intensity of the fever bears no constant relation in the production of insanity. Nasse classified the mental affections originating in fever according as they are the immediate result of the fever itself, as they constitute a prolongation of the delirium when the fever has subsided, or as they arise during convalescence. With regard to the first two conditions we are in want of data; the actual relation of high temperature to delirium is but imperfectly known.

The forms of acute disease commonly followed by insanity are the specific infectious fevers, intermittent fevers, and long agues (especially if they be quartan, and this forms *sui generis* a peculiar form of mania), erysipelas, acute pyrexia of phlogoses, articular rheumatism, acute angina, diphtheria, erythema nodosum, miliary roseola, purpura, febrile urticaria, guttural herpes, &c. Of the forms of acute disease enteric fevers, pneumonia and rheumatism are nearly on an equality as causes. (a)

At present we cannot demonstrate any definite relation between the forms of insanity and the nature of the febrile disease: nor do we know the relative frequency of the various forms of mental disorder after any particular class of diseases. This subject, however, is of such importance that it may be advisable to repeat what I have already said in the "Dictionary of Psychological Medicine." There believes the commonest form of insanity consists in the sudden onset of acute maniacal delirium, characterised by great agitation with hallucination of sight and hearing, its duration varying from fifteen hours to three or four days, and the termination often occurring as abruptly as the onset. This form occurs chiefly after rapid acute diseases, such as pneumonia and tonsillitis and much more rarely after typhoid fever.

One point of clinical interest to be noted is, that after typhoid, typhus, small-pox, scarlatina, cholera, diphtheria, influenza, or malaria, there may be physical symptoms which, when associated with insanity, closely simulate general paralysis of the insane. The general

constitutional disturbances and degeneration of the tissues of the body (especially of the cerebro-spinal system) which occur in pellagra, are frequently attended by morbid mental states. These mental states, however, have nothing unusual or characteristic in their nature to distinguish them from those of other exhaustive diseases. Influenza has frequently proved itself to be a determining cause of insanity, and this more readily in individuals who are predisposed to neurosis.

Considered *seriatim*, after typhoid the cerebral condition may be one of torpor mingled with agitation and hallucinations. This condition may be transitory, or may pass from melancholia into mania and chronic dementia. In many of the more chronic cases, especially those which arise early, there is often great moral perversion with extreme irritability of temper, sometimes there is weakened memory or general apathy and failure to form clear conceptions as to the objective significance of things. Conditions of confusion, anærgia, ambitious monomania, and partial dementia are not uncommonly developed during convalescence. These conditions may be temporary and curable, and they may present no difficulties from a diagnostic point of view. There are other conditions, however, which do present considerable difficulties, and to these I now desire to draw your attention. Occasionally, typhoid fever is attended by symptoms which closely resemble those of acute delirious mania. These are dry tongue, sordes on the teeth and lips, constipation or diarrhoea, foul and offensive stools, quick pulse, temperature 100° or even 105°, prostration, low muttering, delirium, &c. Sometimes an accurate diagnosis is almost impossible. The chief points for guidance are the mode of onset of the symptoms, the presence of the characteristic rash of typhoid, the temperature curve, and the presence of abdominal pain in typhoid, &c. Ehrlich's test, or the Diazo reaction with the urine in cases of typhoid is not confined to such cases; hence, as a diagnostic sign, it is at present of only comparative value. A careful consideration of the case is of the utmost value, for in acute delirious mania it is important to administer stimulants and to give an abundance of easily assimilated food, which, in the case of typhoid might prove disastrous.

A form of insanity has been described by many writers, in which there are many physical symptoms closely resembling those of general paralysis. These symptoms may be affections of speech, or staxy of movement. The speech is sometimes slow, and exhibits a characteristic drawl; the syllables are articulated in a monotonous tone, and with a nasal twang. The affections of the motor system may further be evidenced by muscular weakness, with or without tremors or tremblings of the lips, facial muscles, or even limbs. Westphal has described a peculiar trembling of the head when unsupported in a case in which there were no lip tremors, and in which sensation was unaffected. The pathology of this condition is little known. In chronic cases terminated by death in asylums, anæmia of the brain, or atrophy of the cortical substance, opacity of the pia mater, and excess of the subarachnoid fluid have been found. Jaccoud ascribes the paraplegia following typhoid to congestion of the cord.

In connection with these cases, it is important to remember that they resemble general paralysis in some respects only, i.e., they do not run the usual course of general paralysis, but may become chronic in the form of partial dementia, dementia, or of paralysis associated with insanity, and termed by some "pseudo-general paralysis."

MEMORIALS to the Home Secretary are being signed in Cardiff in favour of the appointment of a woman doctor at the local gaol, in addition to the usual medical officer.

(a) "Post-Febrile Insanity." By Hyalop, in Tuke's Dictionary of Psychological Medicine.

TREATMENT OF UTERINE RETRODISPLACEMENTS. BY VAGINO-FIXATION.

WITH REPORTS OF CASES.

By FREDERICK HOLME WIGGIN, M.D.,

Gynecological Surgeon to the New York City Hospital.

THERE are numerous cases of uterine retrodisplacements giving rise to symptoms which for various reasons are not amenable to the ordinary routine treatment of massage, followed by the application of the tampon or pessary, and for these several operative procedures have been devised. The principal ones are, that known as the Alexander (Liverpool) operation, suspensio uteri, brought forward largely by Howard Kelly, of Baltimore, and that of Mackenrodt, of Berlin.

To this latter operation it is the purpose of this paper to particularly call attention. The simplicity of its technique, the safety, ease, and rapidity with which it can be performed, and the good results obtained, make it, in the writer's opinion, a formidable rival of the other methods mentioned for the relief of the class of cases under consideration. The technique described will be that employed in the cases about to be narrated. The patient is prepared as for a vaginal hysterectomy and is placed on the table in the dorsal position with the thighs flexed and held in place by a clover crutch. As in this class of cases there is more or less endometritis, it is well to begin the operation by curetting the uterus with a sharp curette, gauze not being placed in the cavity. Any existing laceration of the cervix should be repaired, sutures of catgut being used. These steps having been taken, the cervix is grasped and drawn downward and forward by the aid of a pair of bullet forceps. Then a portion of the anterior vaginal wall about three-quarters of an inch below the meatus urinarius is taken up in the same way and drawn forward and upward, thus stretching the wall. An incision is made beginning at the last-named point and continuing to the cervix. If this wall is more or less prolapsed, the incision, instead of being straight, should be oval, allowing for the removal of sufficient tissue to overcome this defect when the sutures which close the vaginal wound are placed. These flaps are dissected from the inferior surface of the bladder into which a sound is passed and by its aid the thickness of the bladder wall is estimated and its lower border defined. A needle threaded with pedicle silk is passed through the inferior edge of either flap and tied, the ends being kept long. These serve as retractors, and the flaps being held aside, a curved transverse incision is made at the cervico-vesical junction. The bladder is freely separated from the uterus by blunt dissection with the finger, the vesico-uterine fold of peritoneum being divided by the aid of scissors. The patient's hips are elevated, which allows the bladder and intestines to gravitate from the uterus, the fundus of which is brought into view and is seized by a pair of bullet forceps and drawn forward. The ovaries and tubes are inspected after any existing adhesions have been broken up and if diseased are removed. A suture of pedicle silk (No. 12) is passed by means of a curved Hagedorn needle through the left vaginal flap at a point slightly distant from its superior margin, then through the muscular tissue of the anterior uterine wall close to the fundus and then through the right vaginal flap near its upper margin. A second suture of silkworm gut is passed in the same way about one-third of an inch below the first. The uterus being well anteverted, the first suture is tied loosely in the ordinary way and the second is passed through an opening in a small lead shield and is fastened by a perforated shot, which is closed by pinching it with a pair of artery clamps. The balance of the wound in the anterior vaginal wall, after free irrigation with saline solution and the application of hydrogen dioxide if there is much oozing, is closed by means of interrupted sutures of horse hair and the wound is sealed by painting it over with a 10 per cent. solution of iodoform in ether. A small quantity of gauze is placed in the vagina for the purpose of effecting drainage, and an antiseptic pad is applied to the vulva. The time occupied by the operation is usually twenty minutes. The patient's

urine is drawn by the aid of a new catheter, which should preferably be a short one of glass to which is attached a rubber tube, till it can be voided voluntarily, which is generally at the end of the third day. The vaginal gauze is removed about this time, and is not replaced. A daily douche of a weak bichloride solution is given, after which the iodoform solution is again painted over the wound. The vaginal sutures are removed at the end of a week, or sooner, if they begin to cut the tissues. The sutures which hold the uterus in place are allowed to remain for as long a time as is possible. The patient is retained in the horizontal position for two weeks, and is then allowed to assume a sitting posture, and at the end of the third or fourth week is permitted to leave the bed and move about.

CASE I. *Oophorectomy and Vaginal Fixation.*—C. R., a single woman, *æt.* 20, was admitted to hospital on Oct. 27th, 1894. She stated that her first menstrual period occurred during her sixteenth year, that it had been somewhat painful, but regular, and of the monthly type. She had never been pregnant. For the past eighteen months she had had constant pain in her back. She had recently suffered from vaginitis, and since this attack her menstrual periods had been accompanied by severe pain. A bimanual vaginal examination revealed an enlarged tender, and retroplaced uterus, also bilateral enlargement, and tenderness of the tubes and ovaries. On November 7th, after proper preparation, the patient having been placed under ether anaesthesia, the uterus was drawn forward and after dilatation of the cervix its cavity was curetted and irrigated. The anterior vaginal wall was incised, the bladder separated, and the uterus anteverted, as previously described. Both ovaries were found to be somewhat adherent and cystic, and were removed. The pelvic cavity was flushed with hot saline solution, and the uterus was attached to the anterior vaginal wall, and the vaginal wound closed, drainage not being employed. The patient's convalescence was uneventful. Her highest bodily temperature, 100.4° F., occurring on the second day, the highest pulse rate was 90, and her respirations 24, all becoming normal on the third day and remaining so. The patient was catheterised till the evening of the second day, when she voided her urine voluntarily. The wound healed primarily. On the twenty-ninth day the uterine sutures were removed. The uterus was found to be anterior. The patient had had no pain or bladder symptoms.

CASE II. *Vagino-Fixation.*—B. A., a widow, *æt.* 34, was admitted to hospital on Sep. 4th, 1894. She stated that her first menstrual period occurred during her sixteenth year, and that it has been painless, regular and of the monthly type; she had had no miscarriages. One year ago she had given birth to a child. About nine months later menstruation had become irregular and painful and of late she had had a constant pain in her back and left side. A vaginal examination revealed a retroplaced and tender uterus.

As it was evident that the patient was suffering from endometritis, an operation was advised, consented to, and was performed on November 27th, 1894. The uterus, after curettage and irrigation of its cavity and the usual incision of the vaginal wall, was anteverted and its fundus attached to the wall. The patient's convalescence was uneventful. She voided her urine naturally on the third day. Her highest bodily temperature was 99.4°, her pulse ranging from 80 to 97. On December 4th, it was noted that the vaginal wound had healed primarily, that the patient had complained of no pain or bladder symptoms. On the thirty-first day the deep sutures were removed and the uterus was forward in a good position. The following day the patient was allowed to leave the bed. Her menstruation recurred on January 1st, lasting four days and was almost free from pain.

CASE III. *Trachelorrhaphy — Oophorectomy — Vagino-Fixation.*—H. D., a single woman, was admitted to hospital on Nov. 16th, 1895. She stated that her first menstrual period had occurred during her nineteenth year and that it had been somewhat irregular. She had been costive. She had recently been confined, since which time she had had a constant dull pain in her side and back radiating into her lower extremities. On making abdominal pressure a localized tenderness was found to exist in the right inguinal region. Vaginal examina-

tion revealed an enlarged retroplaced and tender uterus with a cervical laceration on its right side, also an enlarged and tender tube and ovary on the same side. The operation was performed on the 24th of January and consisted of a trachelorrhaphy. Curettage followed by the incision of the anterior vaginal wall, anteversion of the uterus, the removal of the right tube and ovary and the fixation of the fundus to the anterior vaginal wall. The patient's highest bodily temperature following the operation was 100° F., on the day following that on which the operation took place and became normal on the afternoon of the succeeding day. The patient voided her urine normally on the fourth day. The patient complained of no pain or bladder symptoms.

CASE IV. Amputation of the Cervix and Vagino-Fixation.—T. P., a single woman, was admitted to hospital on Dec. 10th, 1894. She stated that her first menstrual period occurred during her fifteenth year, that it had been regular and of the monthly type, but accompanied by severe pain. She had given birth to one child seven years previously. About three months prior to her admission she had had an instrumental abortion performed. This had given rise to a severe pelvic pain which was accompanied by a bloody vaginal discharge. A bimanual vaginal examination revealed an enlarged and tender uterus with an hypertrophied cervix. An operation was advised and was performed on Dec. 11th, and consisted of curettage, amputation of the cervix and fixation of the uterine fundus to the anterior vaginal wall. The patient's highest bodily temperature 100.2° F., was on the day following that on which the operation was performed. The patient passed her urine voluntarily on the fourth day. The vaginal wound healed primarily. There were no bladder symptoms. On the 38th day the uterine sutures were removed and the patient was allowed to sit up. On Jan. 30th, 1895, it was noted that the patient had had no pain or bladder symptoms, that the uterus was anterior and that her menstruation following the operation, while rather profuse had been painless.

The notes of several other cases in which similar operations were performed, from Oct. 1894, to Feb. 1895, have unfortunately been lost but their stories were of the same tenor as the foregoing. It is unfortunate that these patients could not have been observed for a longer period of time but it has been shown that this operation is not one of difficult performance, that it permits of the examination of the uterus and its adnexa and their removal even if somewhat adherent. If, however, bilateral disease of these organs exists, the writer's experience leads him to believe that instead of fixation of the uterus following their removal a hysterectomy should be performed. That vagino-fixation is followed by little constitutional disturbance and no danger to life, so far there having been no fatal cases recorded; that it can be quickly performed; that it places the uterus in good position; that it is not usually followed by pain or bladder symptoms; that it leaves no scar or liability to hernia and that it lessens the danger of intestinal adhesions. Others have found that the uterus placed anteriorly by this operation remained in good position even after pregnancy and delivery at full term.

While more time must elapse before we can pass final judgement on the value of this procedure, the writer believes that it will eventually be recognised as the proper means of treatment for many cases of uterine retrodisplacements which give rise to symptoms.

Selected Formula.

The following prescriptions are taken chiefly from Dr. Murrell's forthcoming work on "Pharmacology and Therapeutics," an advance copy of which is before us:—

IODIDE OF SODIUM MIXTURE.

Iodide of Sodium, 15 grains;
Water, half-an-ounce.

To be taken in a cup of black coffee at bed-time in cases of asthma.

BENZOL DROPS.

Benzol, three drachms.
Oil of Peppermint, one drachm;
Olive Oil, two ounces.

Ten drops on sugar every four hours in chronic bronchial catarrh.

APOMORPHINE MIXTURE.

Solution of Apomorphine (1 in 50), 10 minims;
Dilute nitro-hydrochloric acid, 5 minims;
Tincture of Virginian Prune, 20 minims;
Syrup of Virginian Prune, 20 minims;
Water to an ounce.

A useful expectorant in cases of chronic bronchitis and winter cough.

AMBER MIXTURE.

Oil of Amber, 10 minims.
Powdered Gum Acacia, 1 drachm.
Syrup of Orange Flower, 2 drachms.
Oil of Anise, 3 minims.
Water to an ounce.

Useful in chronic bronchial catarrh, and in whooping-cough.

SENECIO MIXTURE.

Tincture of Senecio, 1 drachm.
Syrup of Lemons, 15 minims.
Spirit of Chloroform, 15 minims.
Water to an ounce.

For amenorrhœa. To be taken three times a day for four days before the time of the expected period. Either the Senecio Jacobœa or the Senecio vulgaris may be used.

PARALDEHYDE MIXTURE.

Paraldehyde, half-an-ounce;
Tincture of Vanilla, 20 minims;
Rectified Spirit, half-an-ounce;
Syrup, one ounce;
Water to four ounces.

A tablespoonful at bed-time in cases of sleeplessness.

ANTISPASMODIC DROPS.

Oil of Cajeput, two drachms;
Oil of Cloves, half-a-drachm;
Oil of Peppermint, half-a-drachm;
Rectified Spirit to two ounces.

Ten drops occasionally on sugar for flatulence.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, JANUARY 24TH, 1896.

The President, Dr. BUZZARD, in the Chair.

CLINICAL EVENING.

ARTHRITIS DEFORMANS WITH CLOSURE OF THE JAW FROM ANKYLOSIS OF BOTH TEMPORO-MAXILLARY ARTICULATIONS.

DR. JOHN R. LUNN showed a patient, æt. 45, a cabman, who was admitted into St. Marylebone Infirmary July 17th, 1894. Past history: Twenty-five years ago he had rheumatic fever, and from that time most of his joints began to be affected, the knees being the first to become swollen. Two years later his jaw became stiff, and for the last twelve months he has been unable to separate his teeth at all or to take solid food. On admission: It was noticed that both the patient's knees were swollen, and distended with fluid, osteophytic outgrowths surrounded the joints, and most of the articulations in the body were affected with rheumatic arthritis; his neck was stiff, and it could not be turned towards the right or left. Both hip-joints were stiff, and the jaw could not be opened. The upper row of teeth overlapped the lower ones, the latter were loose. On August 18th, 1894, the patient was put under CH Cl₂, and considerable force was used to try and open his mouth, but without success. An incision, two inches long, was then made on the right side in a vertical direction, a finger's breadth in front of the ear; after tying a few bleeding vessels, bone was hit upon, and was thought to be the neck of the condyle, but was the zygomatic process of the malar bone; the neck of the jaw was then divided, but there was no movement of the jaw after its division, so a wedge-shaped piece of bone was freely chiselled out, and the wound was temporarily plugged.

A similar process was gone through on the left side with the exception that the incision on the latter was oblique instead of vertical; a considerable portion of the parotid gland over-laying the maxilla. The jaw was then forcibly opened by the screw-gag so that the teeth were separated an inch. Two teeth were accidentally forced out during the operation. Both wounds were closed and healed by primary union. A wooden gag was put between the teeth and was tied in the mouth to keep the teeth apart, the whole operation lasted nearly two hours.

HYSTERO-EPILEPSY—A CASE REPRESENTING THE CONDITION OF DUAL EXISTENCE.

Dr. ALBERT WILSON, of Leytonstone, showed a girl, *et. 12*, who, in April, 1895, had severe influenza, followed by meningitis and mania. After six weeks the cephalalgia disappeared, and muscular symptoms developed—twitchings, opisthotonos, with lividity and coma. She had many fits a day. In June, 1895, the old symptoms subsided and a fresh train of phenomena appeared. When in apparently her normal state she would suddenly shake, turn a somersault, and enter a new and different mental state. Her memory for all events during health was quite gone—even forgetting the names of things, of the parts of her body, and her own name and identity, and those of her parents. But she would remember in one such fit what happened in a previous one. Thus was established a complete dual existence. By education she learned the names of most things, but always employed baby pronunciation. She would write backwards and that quickly. When these attacks developed she lost all power of walking or standing till about August, 1895. At the early stage she had fits of catalepsy—chiefly rigidity of the flexora. At times she had five or six fits a day, lasting a few minutes, and at her worst period they lasted for days. She recovers from them quite suddenly, is never surprised at her surroundings, but is very composed, and says she remembers nothing of what transpired during the attack. The most striking feature showed itself once when she had severe toothache during an attack. He gave chloroform, and removed two teeth. On regaining consciousness she recognised that the teeth and pain were gone. Her father hypnotised her and brought her to the normal state, when she made the discovery of the blood and the loss of the teeth, but never remembered the previous pain or his giving her chloroform. She had then been in the abnormal state for about three days. There have been many variations, and she has four different existences besides the normal—(1) "Nib" for "old Nick" when she has had violent passion, and biting, and slides down the banisters. (2) "Dreadful wicked thing"—when everything is reversed—black being white, asleep being awake, the head being the foot, and so on. (3) "Allie," when she is amiable and good. (4) Her ordinary fits, as already described. Other phenomena occasionally occur. Thus, she is at times completely deaf and dumb, or there may be loss of memory, so that she does not know during the fits those whom she ordinarily knows. The last three or four weeks a fresh phase has occurred. She is now (in January, 1896) living mentally in July 1895, this having followed on a mental blank of a fortnight's duration. This is shown by her imagining events to have just happened which happened in July, and other circumstances. Her general health and nutrition are good. She has not yet menstruated. Treatment has been rest and quiet and fresh air. Tea and coffee cause attacks of mania. The thyroid treatment has had no apparent effect.

Dr. ALTHEUS said the case resembled those recorded as instances of "double consciousness" in patients who after a brief period of unconsciousness changed in character from reticent and morose to gay and merry, with apparently higher faculties than before. Then, after another period of unconsciousness the character changed back again. In a case of the kind recorded by a French author it was ultimately thought to be an example of somnambulism. Somnambulism, he pointed out, was comparatively frequent in children, especially girls, and it was conceivable that a slight exaggeration of this aberration might determine symptoms similar to those described. In another recorded case in which the patient when 24 years of age suddenly developed this curious quality of personality. She was usually short-sighted and used spectacles, but in the alternative condition she would fling her spectacles

away and developed wonderful visual powers. After two or three hours in this condition she would fall asleep and wake up her former self. These alternations continued for several years. He pointed out everyone led dual existences more or less. There was a waking and a sleeping (dreaming) condition and they were not the same drunk as sober. Moreover, one could often remember things in one condition which one was quite unable to recall in the other. It seemed as if there were two separate cerebral centres concerned which came alternately into play.

Dr. ORMEROD asked whether the author was in a position to affirm that the original attack, which was the starting point of the symptoms, was really meningitis. He suggested that it might have been a febrile attack with nervous symptoms due to the same cause as the symptoms in question, which, for want of a better name, one would be inclined to call hysterical.

Dr. ROBERT JONES observed that these cases of double consciousness usually came on suddenly, often after epilepsy. He mentioned the case of a patient who lapsed after an epileptic attack into a condition in which she remembered nothing of what happened to her previously, and *vice versa*, and he recalled a case of the kind that had been placed on record in which this condition of forgetfulness of events in the ordinary condition lasted for a year, and on the patient having another fit and becoming restored to her ordinary self the events of that year were, so to speak, blotted out. He remarked that when the author's patient tried mirror writing she did not begin as usual with the first letter of the name but wrote backwards, beginning with the last letter. This made him think that she was acting under the influence of "suggestion." The patient appeared to be unduly precocious, and she apparently acted on suggestion rather than from epilepsy or genuine dual consciousness.

Dr. WILSON, in reply, said he did not attend her during the alleged attack of meningitis, when she had a rise of temperature followed by headache and she became very intolerant of light and sound. There was also some delirium and excitement, and he thought probably there was some meningitis. When first asked to try mirror writing she was quite unable to originate an idea and could only copy. He did not think she was acting under suggestion now. He had been very particular at first not to discuss her case before her, but later on when this was done by others it did not seem to make any difference.

A CASE OF MYOPATHIC MUSCULAR ATROPHY IN THE ADULT.

Dr. NORMAN DALTON showed a patient who was quite well until twenty years of age. There was no family history of any trouble of the kind. At present he presented marked indications of general muscular atrophy. When put on his back and told to rise, he first turned on his right elbow and on to the palm of his right hand. Then he got on all fours, but could not rise any more without the aid of a chair. The pectorales majores were atrophied at the lower part, but intact above. The serrati were intact, but the deltoids were weak.

A CASE OF EXTENSIVE SKIN GRAFTING.

Mr. H. PATERSON showed a man, *et. 58*, who, in consequence of extensive cellulitis, lost the skin from the entire front of the thigh and leg. He had recourse to large grafts by Thiersch's method, some of the flaps measuring 5 by 3½ inches. The result had been extremely successful.

Mr. A. PEARCE GOULD asked whether the author had discovered the necessity of keeping these patients recumbent for a long time after cicatrisation had taken place. He pointed out that some surgeons had expressed great dissatisfaction with this mode of treatment, because after healing, the newly-formed tissue easily broke down again. In his own experience that was due to the patient having been allowed to get up too soon.

Mr. PATERSON, in reply, admitted that this had been his experience. The cases that broke down were those in which, healing having taken place, the patients refused to remain in bed.

SUPPURATION OF THE LEFT SHOULDER-JOINT, WITH ARTHRITIS DEFORMANS.

Dr. J. R. LUNN showed a man, *et. 66*, admitted November 27th, 1893, with chronic arthritis deformans and

swelling of left shoulder-joint. He had enjoyed good health until fifteen years ago, when he had his first attack of rheumatism. Since then he had repeated attacks in most of his joints. On admission the man appeared to be ill. He was feverish, restless, and inclined to be delirious. He complained of intense pain in the left shoulder-joint with limited movements, which was very large, tense, and very painful to touch. His temperature was 103.2°; pulse, 110. He was treated with rest, ice-bag, and salicylate of soda, but he did not improve. His temperature rose higher, and he begged for something to be done. The joint was tapped by an exploring needle, and pus was withdrawn. On December 3rd an incision was made in front of the left shoulder-joint, commencing at the outer side of the coracoid process, pus was let out, and the joint explored with the fingers, and a counter opening made behind. The head of the humerus was rough and diseased, which was curetted with Barker's gouge, and the shoulder-joint being washed out with hot water. Iodoform emulsion was introduced, and the incision closed in front, and a small drainage tube was fastened in the posterior wound, which was removed the following day and the wounds healed very soon, and the patient rapidly recovered. In June, 1894, the same shoulder again began to swell and his temperature rose to 102.4° and the man seemed as bad as ever, the pus was again let out and the joint treated as before. Since the second operation the patient has enjoyed good health. He has now marked wasting of the left deltoid muscle and other muscles about the joint, the movements are very limited. He can only abduct his arm slightly, and can raise his arm nearly to a right angle to his trunk, but has no power to keep it there.

A CASE OF TRAUMATIC ORBITAL ANEURISM.

Mr. RAYMOND JOHNSON showed a woman, *st.* 44, who fell on the back of her head four months ago, and was unconscious for seven hours. On recovering she vomited, and at once noticed that the left eye was blood-shot, and the eyelids swollen. On the following day she noticed a buzzing noise in the left side of the head, and this had been continuous ever since. Then the eye became unusually prominent. During the four weeks she had been under observation there had not been any change. The principal points were the prominence of the left eye, without congestion of the conjunctiva or distension of the veins. No pulsation could be either seen or felt, but around the orbit a loud murmur was audible. This was continuous, but was influenced by the rapidity of the heart beat. There was no evidence of neuritis, and no obvious dilatation of the veins of the fundus. Vision was normal except for diplopia, which was dependent upon paralysis of the sixth nerve. He had called it a case of traumatic orbital aneurism, but in the absence of the usual indications he admitted that the diagnosis was open to discussion. He thought that probably there was aneurismal varix of the internal carotid artery and cavernous sinus. The fall probably caused a fissured fracture of the base of the skull, for hæmorrhage at the back of the orbit was noticed within a few hours of the accident. He mentioned that she was at present nursing her child, who had double proptosis, due to a neoplasm in the interior of the skull. Compression of the left carotid did not cause the noise or the proptosis to subside, though both were somewhat lessened thereby.

Mr. GOULD remarked that under the circumstances a communication between the internal carotid and the cavernous sinus would be extraordinary. It must in any case be very minute or there must be some other special condition for the artery to communicate with the vein without causing dilatation of the veins. He pointed out that these cases often got well spontaneously with rest, and he recalled a case at Middlesex Hospital two years ago of a man who came in immediately after the injury with symptoms of acute obstruction of the cavernous sinus, pulsation, proptosis, interference with vision, and a loud bruit. Under rest in bed, without any particular treatment, he ultimately quite recovered.

Mr. W. G. SPENCER doubted the existence of a direct communication between the internal carotid and the cavernous sinus, but suggested that there might be a communication with one of the smaller branches. This would explain the absence of venous distension.

Mr. BOWLBY observed that the diagnosis of these cases was rendered more difficult by the fact that in some nothing whatever was found to account for the symptoms. He remembered one such case, worse than this one, which got perfectly well without treatment. The paralysis of the sixth nerve seemed to point to actual pressure. He thought there might possibly be a communication between the carotid artery and the sinus, probably very minute. Under any circumstances, he said they would probably all agree that the treatment should be of the nature of "masterly inactivity."

IMPAIRED GROWTH OF LOWER EPIPHYSIS OF TIBIA
CONSEQUENT ON STRAIN.

Mr. MANSELL-MOULLIN showed a lad who five years ago, got his foot in a wheel, and it was severely twisted. He was confined to bed for some weeks, and the case was treated as a simple sprain. The lower end of the fibula had gone on growing but the growth of the lower part of the shaft, as well as the epiphysis, of the tibia had not grown and there had resulted an extraordinary malleolar projection twisting the foot into a position of *falce talipes*. He could only walk a short distance and that with great suffering so that something seemed to be required in the way of operative treatment. He suggested excising about an inch of the fibula and bringing the foot into the normal position.

THREE CASES OF PSEUDO-HYPERTROPHIC PALSY.

Dr. FLETCHER LITTLE showed three brothers, respectively 5, 10 and 13, years of age, all suffering from pseudo-hypertrophic palsy. They were the only children and there was no history of nervous disease in the family. The eldest had been suffering for seven years, the second for three years and the youngest for nine months. The two older boys were quite unable to walk. The second had contracture of both the lower limbs.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

MEETING HELD FRIDAY, JAN. 3RD, 1896.

The President, Dr. CONOLLY NORMAN, in the Chair.

LEUCÆMIA SPLENICA. (LIVING EXHIBIT.)

Dr. DENHAM showed the case of a gentleman from Kilkenny suffering from a very large splenic tumour. He was *æt.* 41, with a good family history, and had always enjoyed good health. Five years ago he returned from Queensland, where he had resided some years. The patient first observed the tumour six months ago, and was treated for indigestion. He came under his (Dr. Denham's) care at the beginning of December. He (Dr. Denham) had made four examinations of the blood with Gower's hæmatometer at intervals of a week, with the following results:—

	Red corpuscles.	White corpuscles.
1st -	70 per cent.	9 per cent.
2nd -	73 "	8 "
3rd -	82 "	2 "
4th -	85 "	2 "

Dr. M'Weeney had made stained preparations, which were under the microscope. In these numerous eosinophile cells were to be seen, but Dr. M'Weeney had been unable to find any myelogenic cells. It was remarkable that notwithstanding the size of the tumour and the altered condition of the blood the patient enjoyed very fair health, suffering little or no discomfort. Slight constipation and breathlessness only on severe exertion. The fact that under treatment the number of white corpuscles had markedly diminished, and that no blood marrow cells were discoverable, gave the case decidedly a less hopeless appearance.

CANCER OF THE LIVER.

Dr. PURSER exhibited a specimen of columnar-celled cancer of the liver, which was remarkably firm in its mode of growth. The morbid mass filled the portal vein from about an inch below its bifurcation, to branches so small that they could be barely followed by the naked eye. No primary growth could be detected, unless a small nodule in the mucous membrane of the gall bladder could be

taken as such. The bile duct was flattened by the growth in the portal vein, but did not seem to have been the starting point of the tumour. In places hemorrhage had occurred into the alveoli of the cancer, but there were few signs of degeneration.

Dr. M'WEENEY thought, from the examination he had just made, that the growth was one of papillary adenoma, in the sense in which that term is used by Ziegler. He traced delicate strands of connective tissue running outwards towards the periphery. It was a remarkable fact, he thought, that Professor Purser did not find any primary growth. He remarked on the case of a man from whose chin a tumour was removed—a week after the operation he died, and a *post-mortem* revealed a nodule in the fissure of the liver, but the nodule did not implicate the substance of the organ. He considered the filling up of the portal vein and its branches in the case under consideration as very singular. He contrasted the growth with a growth of supra-renal structure in the substance of the kidney, two instances of which he, on a former occasion, had brought before the Academy.

The PRESIDENT wished to ascertain what was the vascular supply of the growth, and whence came the hemorrhage referred to.

Dr. PURSER, in reply to Dr. M'Weeney, said that the tumour most certainly was not a papilloma. It might be called an adenoma, but he considered the difference between so-called malignant adenoma and cancer was not very great. In reply to the President, he said that the tumour had a blood supply of its own—a fact sufficient to explain the hemorrhage. Whether the blood-vessels of the tumour were derived from the hepatic artery he (Dr. Purser) could not say.

Dr. M'WEENEY said he did not assert that the tumour was a papilloma. What he did say was that he believed that it was a papillary adenoma in the sense in which Ziegler used that term.

The PRESIDENT at this point vacated the chair, which was occupied by Dr. Purser during the remainder of the proceedings.

CANCER OF GALL-BLADDER.

Dr. CONOLLY NORMAN described, as a pendant to Dr. Purser's case, three cases of cancer of the gall bladder. In all three the interest was chiefly clinical. In the first the liver was greatly enlarged. The border was sharply defined, and the right lobe was extremely and uniformly hard. The patient was not jaundiced, was not markedly constipated; there was no absence of bile from the motions. The *post-mortem* revealed some degree of adhesive peritonitis over the surface of the liver, the right lobe of which was infiltrated with cancerous growth. The left lobe was studded with a growth manifestly of the same nature. The gall bladder was filled with rosy pus, and contained sixteen small faceted stones. A rough and ulcerated mass projected into the viscus, but did no damage to the cystic duct. In most of its aspects the case was an ordinary one; still the entire absence of jaundice was remarkable. Microscopic examination proved that the case was one of the usual columnar-celled epithelial variety. He (Dr. C. Norman) knew no *ante-mortem* symptoms by which a diagnosis of cancer of the gall bladder could be arrived at in such a case. *Second case.*—A woman, forty years of age, had suffered for some months from constipation and abdominal pain. There was no fever. The pain, she said, was most marked at night, and she attributed it to the fact that there were demons in her inside. On the 8th of September, 1895, she got a severe attack of vomiting. On examination she was found to present an enlarged area of hepatic dulness. There was also found a well-defined small knob in the position of the gall bladder. The diagnosis was made of gall-stones. The patient suffered from obstinate constipation. There was slight jaundice which never increased. Vomiting continued very troublesome, but was never feculent. Though the diagnosis of gall-stones was ventured upon, it was not deemed expedient to take any operative measures against this condition. She died on the 28th of September. The *post-mortem* appearances were as follows:—There was a good deal of general peritonitis. At the notch for the gall bladder there was, in the substance of the liver, a mass of cancerous infiltration. The point of interest to

him (Dr. Norman) was that he made the mistake of supposing that this hard, small knob was something in the gall bladder. *Third case.*—An old woman, about sixty years of age, who got a rather sudden attack of jaundice. On examination the liver was found to be enlarged, and at a point corresponding to the notch of the gall bladder there was a large, pear-shaped prominence, easily felt by the hand, and diagnosed to be a gall bladder full of stones. She gradually became more and more deeply jaundiced, but the area of hepatic dulness became less. She never had hematemesis. She died apparently from exhaustion. The *post-mortem* revealed no traces of previous peritonitis, and the tumour felt *ante-mortem* proved to be the gall bladder, but its distension was due to a cancerous mass blocking up the ducts and not to gall-stones.

The Section then adjourned.

LIVERPOOL MEDICAL SOCIETY.

MEETING HELD FRIDAY, JANUARY 16TH, 1896.

The President, DR. CATON, in the Chair.

CASES.

MR. NEWBOLT reported a case of "Traumatic Epilepsy" resulting from a compound fracture of the skull. The original injury occurred on Dec. 13th, 1888, at Boston, U.S. The man was trephined and bone and brain substance were removed. He remained well for two years, except for the presence of hemianopia. At the end of this time epileptic fits commenced and occurred at intervals, varying from two weeks to two months and a half. The fits invariably started in the left wrist and the injury was on the right side. On admission there was a depression of the right side of the skull, three-quarters of an inch deep, two inches from above downwards, and one and a half inches from before backwards, the centre of the depression being about two inches above the right ear. At the bottom of this depression there was pulsation. Mr. Newbolt trephined over the wrist centre and finding nothing, removed the bone between the trephine centre and the original depression. The edges of the depression were pared and the adherent parts separated and a sharp spicule of bone found in the anterior cornu removed. The bone was replaced and the wound entirely closed, everything did well. The man had no fit for seven months when he had a slight one; another, seven months later; and a third, four months after this, so that there is, so far, decided improvement. Patient was shown.

Mr. ROBERT JONES related a case of "Rapid Gangrene of a Hernial Sac." The patient, a man, *æt.* 48, had been ruptured for some months, and had worn a truse. With this exception he had been perfectly well until December 18th, 1895. On this date the hernia came down and he vomited, at the same time suffering intense agony. The gut was reduced without the slightest difficulty by a neighbouring surgeon; the patient, however, was not relieved, and was admitted to the Southern Hospital. On admission, the hernia was down, and was again reduced with ease, but as the symptoms became intensified it was decided to operate. Five hours after the first onset of symptoms the sac was exposed; it was perfectly black, though it partially retained its consistence and its shining peritoneal appearance. On opening it, thick and curdy discharge containing particles of vegetable matter, somewhat like pieces of grape skin escaped. The bowel was congested and otherwise sound, but on lifting it up carefully a tear, $\frac{3}{4}$ in. long, was found on its posterior aspect, apparently of quite recent occurrence. There was no abnormal constriction at the internal ring, but a quantity of discharge escaped from the peritoneal cavity, and the gangrene of the sac extended to the internal abdominal ring. The sac was excised, the tear in the gut closed with sutures, and the abdominal cavity washed out, but the man only survived a few hours. *Post-mortem*, the intestines were greatly distended, much congested, and here and there bathed with purulent fluid. The sutured portion was quite watertight. This case, as far as could be discovered, was unique in surgical literature. It was extraordinary that a hernial sac, not strangulated, should slough in less than five hours

without the participation in the process of any of its contents, and is suggestive of micro-organism.

Mr. R. H. MURRAY showed two children upon whom he had operated for "Extroversion of the Bladder." He had used lateral skin flaps so arranged that their raw surfaces were next the bladder mucous membrane. He greatly preferred this method to the more usual plan of a reversed skin flap, as it was much more simple and there was no fear of phosphatic deposit, which, however, was a frequent cause of annoyance when the reversed skin flap was employed, owing to the increased growth of hair in this flap.

Mr. RUSHTON PARKER remarked that a number of years ago he had operated successfully in three cases of boys, by a method devised and described by Mr. Greig Smith in the *British Medical Journal*, a great improvement on the plan of the late Mr. John Wood. A pear-shaped flap of skin was dissected off the abdomen and turned down as a front lining to the bladder and urethra. The raw surface of this flap was then covered with skin detached from the sides of the previous wound, and stretched to meet over it. The result in each case was union almost throughout by first intention, the patients sitting in a hip-bath of warm boracic lotion. In a fourth boy he had failed, owing to sloughing of the entire flaps, due apparently to absence of subcutaneous fat, although the operation was perfectly satisfactory. In a female child he had also done a very satisfactory operation, but the child died in two days from summer diarrhoea. He complimented Mr. Murray upon the good results attained by him in the examples of Trendelenburg's operation exhibited at the meeting.

Mr. ARTHUR WILSON had performed the operation advocated by Mr. Murray, but not with such success. He thought, however, that it was the best of the operations now advocated, but that a certain selection in the cases would be necessary. He suggested that for those in the better classes it would be found that a skilful surgical mechanician was as useful as the surgeon.

Dr. IMLACH asked the surgeons who had practical experience of the operation, what age they preferred the child to be, whether they would always operate at once or wait until the child was two years old or more? He had recently advised a mother, with an infant only six weeks old, to wait at least six months.

Mr. ARTHUR WILSON showed the lungs from a case of sarcoma, the primary growth being over the internal condyle of the femur. The specimen demonstrated with how small a quantity of healthy lung tissue it was possible to aerate the blood.

Dr. BUCHANAN read a paper on

LEUCOCYTHÆMIA.

After giving a brief *resumé* of etiology and clinical features of the disease. The histology of the normal blood discussed, particularly in relation to the leucocytes, introducing the classification of Wharton Jones, Max Schultzze, and Ehrlich; the latter's methods of examination were discussed relative to the chemistry of dyes and solvents of the same. Finally, as a basis for comparison in diseased conditions, the classification of the wandering cells of mammalia as laid down by Kanthack and Hardy was adopted. Comparing blood in six cases of leukæmia, examined by the most approved methods, two forms may be recognised, possessing definite hæmatological features.

1) Characterised by: Great leucocytosis and the presence of certain cellular elements not usually found in normal blood: (a) Large atypical eosinophile cells, with coarse granules, in extraordinary numbers; (b) Large unicolor cells, "myelocytic," similar to normal marrow cells; (c) Transitional forms from (b) through (a) to the ordinary finely granular eosinophile cell, the latter variably increased or diminished; (d) Forms of (c) devoid of granules, and many so shrunken as to suggest a retrogressive change; (e) Lymphocytes and small basophile cells in the later stages, with many atypical large basophile cells: these are found in cases accompanied by enlargement of lymphatic glands; (f) Many nucleated red blood corpuscles of the megaloblastic and normoblastic type. (2) Lymphatic form, great leucocytosis with: (a) Small lymphocytes in great abundance; (b) Large hyaline cells increased; (c) Transition forms from "a" through "b" to large atypical basophile cells; (d) Nucleated red blood corpuscles numerous; (e) Eosinophiles, coarse and fine

diminished; (f) also of myelocytes. Mixed types of both exist. Class 2 may be associated with Class 1 in the latter stages. Class 2. Earl. Two pure cases were illustrated. The use of colour preparations of the blood is necessary to distinguish either form, and to differentiate the disease from any other associated with similar clinical signs. Two cases of greatly enlarged spleen and lymphatic glands were illustrated, showing none of the above peculiarities in the blood.

Dr. GLYNN remarked upon the rarity of the lymphatic form of leukæmia and considered it curious that it should be so, since, if the disease originated in some form of irritation, the lymph glands seemed more likely to be exposed to such irritation than the spleen or bone marrow. He had examined the blood in several cases of pneumonia, with the view of determining the existence or otherwise, of leucocytosis, but so far had not formed a definite opinion as to the value of this procedure as an aid to prognosis in such cases.

Dr. ABRAM said that Virchow had long ago shown that the thymus was persistent in leukæmia, and that this no doubt explained the presence of a mediastinal growth in leukæmia. He admitted that Ehrlich's neutro-phil-granule was really a feebly oxyphil granule, but thought the destruction of feebly and strongly oxyphil granules was useful, as the former were mainly increased in leucocytosis, the latter in leukæmia. He agreed with Prof. Sherrington that the strongly oxyphil mono-nucleated cell represented the marrow cell and the more readily because it showed no amoeboid movement. Leukæmic blood is deficient in alkali and contains no lecithin. He drew attention to the excess of uric acid formed in the urine of leukæmic patients, and pointed out that this phenomenon agreed with the view of Horbaczewski that uric acid was derived from breaking down white corpuscles.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL AND OTOLOGICAL ASSOCIATION.

MEETING HELD FRIDAY, JAN. 17TH.

The President, Dr. STOKER, in the Chair.

Mr. LENNOX BROWNE read a paper suggesting the abolition of gargling in the treatment of Diseases of the Throat, in which he showed that fluids were not brought into contact with the posterior surface of the pharynx if used as gargles in the ordinary way, and also expressed his opinion that silver nitrate swabbings were useless, if not absolutely harmful.

Drs. GRANT and MACNAUGHTON-JONES took part in the discussion.

The PRESIDENT showed the following cases, treated by oxygen gas.

A Case of Chlorotic Ozæna.—The patient had suffered for two years from a very offensive discharge and smell from her nose. The oxygen was applied every alternate hour during the day, and on the third day the offensive smell had disappeared. She had been sixteen days under treatment and neither crusts nor discharge were to be seen.

A Case of Syphilitic Ozæna.—Patient had been bad for five years, and had lost the septum and all the turbinated bodies, and there was a large opening into the right antrum. During last August she was treated for four weeks by oxygen being passed into her nose every alternate hour during the day. At the end of that period neither smell nor crusts remained, and now, after the lapse of several months, without further local treatment, she remains free from any sign or symptom of ozæna.

A Case of Purulent Middle Ear Disease.—The patient, a girl, æt. 13, had suffered for seven years with disease of the middle ears, accompanied by profuse discharge, smell, and constant pain, and there was great swelling and ozæna. She was very deaf and there was great bagginess and swelling of the meatus. She had now been nine weeks under treatment, oxygen having been used three hours daily at intervals. At the end of the first week the discharge, pain, and smell had almost disappeared, and now all that remained was a little watery discharge from the outer part of the meatus. Her hearing is vastly better, and she can now hear a watch at two feet, that she could only hear at two inches, eight weeks

ago. Before oxygen was begun, almost every other known form of treatment had been tried but without success.

Dr. ST. GEORGE REID showed cultures of various organisms treated so as to represent the conditions obtained in oxygen treatment.

Drs. Grant, Macnaughton-Jones, and Milligan also joined in the discussion.

Dr. MILLIGAN related the notes of a case of

COCHLEA APOPLEXY.

The patient, a man, *æt.* 42, retired to rest in his usual good health, but woke up the following morning with severe tinnitus in his left ear, upon which side [also he was perfectly deaf. His previous health had been good. Syphilis was denied, but an attack of gonorrhœa twenty years previously was admitted. The patient was a hard-working business man, consumed a considerable quantity of alcohol and had a large appetite. His arterial tension was somewhat high, and the small vessels of his face distended. There was no nausea, no vertiginous attacks, and his power of calligraphy was perfect. Upon testing with various tuning-forks, it was found that the higher tonic limits was abolished and that he was unable to hear any note from a Galton's whistle. He was put upon a mild diet and small doses of alcohol. Iodide and bromide of potassium were also ordered, and free counter-irritation over the left mastoid processes. Subsequently hypodermic injections of pilocarpine were tried, but nothing gave the least relief. Dr. Milligan showed a rhinolith removed from the right nasal passage of a young woman. It was discovered quite accidentally, and was found to lie between the inferior turbinated body and the septum. There was no history of the previous introduction into the nose of any foreign body, and its presence caused no inconvenience. It was removed by means of a pair of forceps. Dr. Milligan also showed microscopic sections of a tubercular mass removed from the right nasal passage of a man who had previously suffered from *lupus nasi*, and also sections of a fibro-connective tissue growth removed from the vault of the naso-pharynx of a boy, *æt.* 11. Scattered throughout the fibrous bundles were islets of somewhat active round-celled growth as if there was a tendency to malignant degeneration.

Dr. PEGLER showed a section of a polypoid growth from the surface of the membrana tympani. It contained hairs embedded in its substance. Mr. Lake and Dr. Milligan considered it an ordinary fibrous polypus.

Mr. MAYO COLLIER opened a discussion on

THE CAUSES AND CONSEQUENCES OF CHRONIC NASAL OBSTRUCTION,

and exhibited a number of casts and patients with great distortion of palates and upper jaws. They illustrated the more serious effects of neglected obstruction of the growing skull. The arguments were placed before the meeting under the following propositions:—(1) That the physiological functions of the normal nose are essential to the well-being of the respiratory apparatus. (2) That stenosis of the nasal respiratory tract, in varying degrees, is present in a large percentage of civilised beings. (3) That stenosis of the nasal chambers are seldom or never hereditary. (4) That temporary nasal obstruction precedes and determines chronic nasal obstruction in most cases. (5) That temporary and permanent nasal obstruction induce, sooner or later, collapse of one or more of the walls of the nasal chambers. (6) That most of the commoner diseases of the nose, naso-pharynx, larynx, and ear, are subsequent to and consequent on chronic nasal obstruction.

The opening was well received, and led to an animated discussion.

THE HUNTERIAN SOCIETY.

CLINICAL MEETING HELD WEDNESDAY, JANUARY, 22ND.

The President, MR. CHARLES J. SYMONDS, F.R.C.S., in the Chair.

DR. SHADWELL showed a case of unilateral spasm of the face in a woman; there was a history of previous hemiplegia of the same side. The spasms came on after confinement.

Sir HUGH BEEVOR showed a case of tremor of the hand

in a girl of 16; the movements were athetoid in character and probably functional in origin.

Dr. F. J. SMITH, Dr. DAVIES, Dr. COTMAN, and Dr. RAWES discussed these cases.

Dr. WOODS then showed two cases of post-herpetic neuralgia of some years' standing, which he had treated with very marked improvement by suggestion.

Sir H. BEEVOR said these cases were two of his, previously shown at the Society, and corroborated the statements of Dr. Woods as to their improvement, which was indeed manifest to all the Fellows present.

Dr. FRED. J. SMITH showed—(1) a case of hemianopsia; (2) a case of motor aphasia; and discussed the seat and nature of the lesions.

Dr. HOPE GRANT shewed a case of seborrhœic eczema in a man of 30.

Dr. ETTLES showed a case of severe acne.

Mr. OPENSHAW showed—(1) a case of congenital dislocation of the hip; (2) a microcephalic idiot with talipes; (3) a case of Potts' fracture, with dislocation of the foot backwards.

A case of contracture of the arm following severe injury, and treated by division of tendons above the wrist, was shown for Mr. TUBBY.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, Jan, 25th, 1896.

THEOBROMINE.

DR. HUCHARD, the great authority on cardiac affections, spoke on the properties of theobromine before the meeting of the Hospital Society. He said that for the last two years he had employed theobromine as a diuretic in cardiac and renal affections, and considered it to be much superior in this respect to digitalis and caffeine. His mode of prescribing it was to give the first day six powders of ten grains each, the second day eight powders, and the third day, ten. This dose, which he considered a maximum, he continued for three more days. Sometimes, in order to prolong the diuretic effect, he gave the day following one-fiftieth of a grain of digitaline. Theobromine is not toxic nor does it injure the renal epithelium; it is especially useful in interstitial nephritis and those heart diseases complicated with kidney lesions.

A RING ON THE PENIS FOR FOURTEEN YEARS!

A most extraordinary case of a ring buried in the penis for fourteen years has been reported in the *Bulletin Medical* by Dr. Lefaive. In September last he was called to a patient who complained of not being able to urinate except by drops and with exquisite suffering. On being questioned the patient confessed that when 12 years old and at school he passed his penis through a brass curtain ring. The organ having swelled considerably the ring could not be withdrawn. In spite of his sufferings the boy kept the matter quiet. By degrees the ring ate its way through the skin into a circular groove, and in course of time the parts healed completely over it, so that it was lost to sight, his sufferings being all the while intolerable! Twelve years afterwards the patient married, but at the first attempt to fulfil his marital duties, the penis became greatly inflamed and contact very painful. He bore valiantly with his infirmity for two years longer, but at last had to appeal for medical aid. When examined, the prepuce and the glans were found to be enormously swollen and of a phlegmonous aspect. It was impossible to find the meatus and all attempt at catheterism increased the agony. About the middle of the penis could be seen a circular white band representing a cicatrix and at this point could be felt the ring embracing the cavernous bodies.

After having chloroformed the patient Dr. Leflaive made a longitudinal incision through the dense cicatricial tissue, which gave issue to a certain amount of pus; at the bottom of the wound could be seen the ring. A director was passed under it and the foreign body was cut through by means of a bone forceps and thus removed. The patient recovered very quickly.

In commenting on this almost incredible case the author observed that nowhere could be found in the annals of medicine a case in which a metallic ring had been buried in the penis for fourteen years without calling for surgical interference.

HERR RONTGEN'S SENSATIONAL DISCOVERY.

Herr Rontgen, of the University of Würzburg to whose discovery, a new conducting agent of light, you have already drawn attention, is attracting considerable attention in French medical circles. We now know that to arrive at this unexpected discovery the *savant* employed tubes of glass in which the void was as perfectly made as possible. Through these tubes a current of induction was passed and it was by the prolonged light of the electric spark that Prof. Rontgen was able to photograph a series of *invisible* objects, such as copper coins in a wooden box tightly closed, and the bones of the hand of a person who was working with him in his laboratory. In both cases the effect was marvellous; the photographic proofs showed distinctly the money and the nails of the box, but of the wood there was no trace; in that of the hand all the bones could be plainly counted, it was that of a skeleton and not of a living person.

M. Poincaré, the illustrious mathematician, presented last week to the Academy of Sciences at Paris, a certain number of these photographic proofs, which, naturally excited no small amount of curiosity.

Prof. Lannelongue thinks that this discovery will be of immense advantage to surgeons as by it it will be possible to localise foreign bodies, as bullets in the muscular tissue and calculi in the bladder, without having to use the sound. He proposes to try it in his hospital service.

FOREIGN DOCTORS.

A press campaign has been set on foot within the last few weeks against the invasion of foreign students, and especially those who intend, after obtaining the diploma of Doctor of Medicine, to live and practise in the country. The actual number of foreign students in the medical faculties of France is 1,200, of which 1,000 are in Paris alone. In Germany the numbers are four times as many. Nevertheless, our French *confrères* believe that the principle of protectionism should extend to the Universities, and many propositions have been formulated to check the zeal of foreign competition on their own ground. The *Gazette des Hôpitaux*, for instance, proposes that the diploma of Doctor be granted to any foreigner who passes the necessary examinations as a purely honorary title, and without the right to practise in France.

Another paper suggests that a decree should be promulgated to the effect that "no person can practise medicine in France unless he be French born or naturalised." It is very possible that this movement may take a practical shape, and that the M.D. France will, in the near future, constitute, in fact, only an honorary title for foreigners. The result is not difficult to foresee.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, Jan. 24th.

THE MEDICAL SOCIETY.

THE first meeting of the year was held on the 8th inst., when nearly all the officers of the former year were re-elected—Prof. Virohow as President, and Herren v. Bergmann, Senator, and Abraham as Vice-presidents. Although no decision has yet been reached as to the employment of the Bleichröder legacy, which, it will be remembered, amounted to a million marks, and was intended for the benefit of consumptive patients, the subject of an institution for the special treatment of tuberculosis has not been lost sight of. In fact, such institutions founded by the city are in actual existence, but their sites have been unfortunately selected. They have been erected on the city drainage fields at Malchow and Blankenfelde, and not unnaturally the nature of their surroundings has marred their usefulness. Patients object to be treated in such localities, and the consequence is that the institutions are left severely alone. The present position of the subject, therefore, is not a satisfactory one, and a desire has been felt in more than one quarter to improve it. Two distinct committees have already been formed for the furtherance of the object aimed at—viz., the best treatment for tuberculous patients in suitable localities. The first committee has been formed under the protection of the Imperial Chancellor, and in connection with the Red Cross Society, with the object of erecting and supporting in various parts of Germany institutions for the treatment of sufferers from tuberculosis. A second committee under the direction of Prof. Leyden, Charité Director Spinola, Geheimrath Althoff, of the Cultusministerium, and Prof. B. Fraenkel will take special charge of the city of Berlin, and Mark Brandenburg to provide it with institutions for a similar purpose for those of limited means. A considerable sum has already been subscribed for the purpose. These institutions will be entirely for sufferers without means, or with limited means; those who are able to provide all treatment for themselves will be left to their own resources.

At the meeting of the Hufeland Society, Hr. Schleich read a note on

THE THERAPEUTIC USE OF ANÆSTHETISING FLUIDS.

He said it was known that Karl Hüter had injected a 3 per cent. solution of carbolic acid into the neurilemma in a case of sciatica in a patient who had suffered from a very painful and intractable form of the disease with the result that it had not returned twelve years after the treatment. Solution of methyl violet showed a similar action depending on its anæsthetising power. In the speaker's first attempts at injecting such solutions his object was, by continuous mechanical pressure by the fluids injected, to produce atrophy of the part. Since 1893, he had treated inoperable tumours in this way, and found that, in addition to the atrophy thus brought about, a distinct allaying of pain was observed. Even a shrinkage in *nevi* was observed after the "hydraulic tissue massage." He had treated many cases of *tic-douloureux* and trigeminal neuralgia successfully by such injections. He had used hydrochlorates for the injections. In one case of gout, in which the pain did not return for a year, it was possible that some chemical change contributed to the result. If fresh solutions made from recently treated

salt were made use of there was never any after pain, and no injurious results had ever followed.

THE COLLECTIVE INVESTIGATION INTO THE SERUM TREATMENT OF DIPHTHERIA.

The Imperial Health Office has just issued its report for the second quarter of last year. In that period 2,130 sheets were returned, from which the following figures were obtained:—In 1,278 cases the diagnosis was confirmed bacteriologically. Out of the total number 1,812 or 85.1 per cent. recovered, and 306 or 14.3 per cent. died. When the hopeless cases are taken out of the calculation, i.e., such as died within 12 hours of the commencement of the treatment, the mortality is reduced to 13.3 per cent. This rate is lower than even that of the previous quarter. A comparison of this rate with that of previous years will show that a decided change for the better has taken place whatever be its cause. Since 1883 the mortality in diphtheria has been as follows:—

1883 ... 28.9 per cent.	1899 ... 25.4 per cent.
1884 ... 25.2 „	1890 ... 28.6 „
1885 ... 23.4 „	1891 ... 27.1 „
1886 ... 24.5 „	1892 ... 29.6 „
1887 ... 23.7 „	1893 ... 30.1 „
1888 ... 28.0 „	

In the first quarter of 1895 it was 17.3, and in the second 14.4 per cent., and for the half year 15.9 per cent., and amongst those cases in which the injections were begun on the first or second day of the disease the mortality was 6.4 per cent.

In the *Deutsch Med. Wochenschr.*, 50/95, Prof. Brieger has an article on

THE TYPHOID BACILLUS.

It is known that Elsner discovered a method of cultivating the typhoid bacillus on a nutrient soil to which potassic iodide had been added, and Prof. Brieger has been recently engaged in putting the method of diagnosis provided by the process into practice. The results obtained were "extremely" satisfactory as in all the suspected cases of typhoid the bacteriological investigation confirmed the diagnosis within 48 hours. That it really was the typhoid bacillus that was being cultivated was proved by Pfeiffer's test. A moment's consideration will show the great value of such a discovery, especially when a method of distinguishing the bacterium coli from the typhoid bacillus, and which grows with it, has been discovered. This method of diagnosis was employed in eleven cases. That three out of the eleven cases were those of nurses shows the necessity of having the dejecta of those having dealings with typhoid cases examined when illness of any form makes itself evident.

THE NEW PHOTOGRAPHY.

At the meeting of the Society fur Innere Medizin of the 6th inst. Hr. Jastrowitz made a reference to the discovery of Prof. W. C. Röntgen, of Würzburg, and drew attention to the vast importance this wonderful discovery would have in medicine. He showed a photogramme taken by Prof. Röntgen that Prof. Goldstein, of the Observatory, had placed at his disposal. On it was shown the skeleton of the human hand plainly shown, even to the finest details, surrounded by the shadowy but still easily recognisable soft parts. *The photogramme was taken from a living man.* He then explained the method in which the photograph was taken as communicated to the Würzburg Physical Society. The discoverer was discharging a Ruhmkorff apparatus through a tube containing no air

This tube was covered with a dark paper or cardboard, so that the luminosity occurring at the cathode at the discharge could not be seen. As he was working in a dark room he noticed a fluorescence lighted up on a plate charged with barium platino-cyanur when the discharge from the cathode took place, whichever side of the plate was turned to the tube. It was evident that rays that were invisible to the human eye passed through the dark paper to the plate. This happened even when the plate was removed a distance of 2 metres. The fluorescence lighted up at every discharge. He then replaced the paper by other and various media, by an oak board 2 to 3 centimetres thick, by a book of 1,000 pages, by thin metallic plates, by india-rubber plates, and the rays passed through all.

As the discoverer continued his investigations with the structure of these rays he found them possessed of active chemical properties, and he was able to take the photogramme shown. The rays passed through the soft parts and were arrested by the denser bones whence a distinct image of them was formed on the sensitive plate. He photographed the contents of a wooden box. He photographed from one room into another, the door being closed; in short, he could see through closed doors and into closed chests, for the rays passed through the wood. This will surely be a wonderful aid in cases difficult of diagnosis.

Austria

[FROM OUR OWN CORRESPONDENT.]

Vienna, Jan. 24th, 1896.

ÆTIOLOGY OF LEPROSY.

KAPOSI resumed his clinical lecture by reviewing the different opinions which have been entertained in the past concerning the ætiology of this persistent disease. All our rational opinions must be founded on its pathology, but the morbid changes observed have been variously interpreted. For a long time the disease was conclusively shown to be hereditary, which was satisfactorily admitted from the histories obtained of families residing in districts where the genealogy of different stocks could be traced in the registers of different parishes. Danielsen and Boeck have spent much time in endeavouring to disprove or establish this doctrine. The latter followed healthy children, who had been born of leprous parents, to America, who after a time had settled on that Continent, and became afflicted with the disease. There may be a certain amount of error in connection with this question of heredity, as many of the families had intermarried and resided in the same neighbourhood for generations, thus fixing the transmission temporarily, as we find it disappearing in many districts without any apparent cause, which would not occur if heredity was the base of transmission. Climate and seaboard residences have also been accused of producing the disease, but when we find inhabitants of Lebanon far removed from sea or low elevations being attacked, we are forced to change our opinion concerning this origin. We have another strong proof against heredity, which long survived in cases of people who had reached their fortieth and fiftieth years, who had always enjoyed perfect health and having descended from a healthy stock, subsequently decided to visit St. Louis or Rio Janeiro where leprosy is prevalent, and returning home after a short residence, become afflicted with the

disease. We have many cases recorded of this nature where healthy people visit affected countries returning home with the disease. These facts point strongly to an infectious character which may be miasmatic in its origin, but of this we cannot say more. Following this part of the investigation the bacillus lepræ has been isolated and is affirmed to be regularly found in the morbid patients as the bacillus of tuberculosis is found in the sputum. But another difficulty presents itself in the feebleness of infection. Animals have been operated on by vaccinating with the bacillus lepræ, but the results have always been negative. We are not, however, justified in accepting these results as conclusive against transmission, seeing that syphilis cannot be produced in animals any more than leprosy. We have on record cases where the human subject has been inoculated and continued perfectly healthy. There is another interesting case of a culprit who was condemned to death, and having the sentence commuted to a vaccination experiment with leprosy; he remained perfectly free from the disease for three years after operation; but on cutting out the skin at the seat of vaccination the bacillus lepræ could be found in abundance. In the course of eight years after leprosy showed itself. This case, though carefully observed, is found to be of little value when we consider that he was transported to a neighbourhood where the disease was epidemic, and it was further shown that he had descended from a leprosy family. We have another class of cases to relate where medical men, their wives, and families have gone to leprosy districts and established leprosy hospitals, there associated with the diseased people, and no transmissions of leprosy have been observed. There are many nurses who have attended to patients of this class without any bad results.

Not long ago the medical world was startled by an announcement that leprosy was rapidly increasing. It is needless to add that this is a fallacy which often occurs when public attention is earnestly applied to investigate a subject long forgotten or neglected by its unobtrusive presence. At the present time official regulations are stringent, and closely scrutinise subjects that would in all probability have escaped notice had some fertile mind not inflamed the enthusiast to collect statistics. These numbers are greatly increased by the accuracy of diagnosis in our own time as compared with the past. We are now convinced that many obscure cases were unrecognised, and thus escaped the vigilant eye of the accurate statistician.

With regard to the treatment of these lepers it is argued that isolation is the primordial agent in the remedy. Nothing could be more opposed to the truth as daily experience amply testifies to the low infectivity of the disease. The bacillus may be transmitted by wounds, but it is denied admission to a new host if this condition be absent. It should be clearly understood that there is a difference between "infection" and "contagion." We all know that pityriasis versicolor depends upon the fungus microsporon furfur, but none of us would venture to affirm that the disease was infectious though it might be granted that it was contagious. All our experience shows that it is a difficult task to make the micro-organism strike and develop in a new soil after it has been transferred, which should convince us that the disease is not infectious. It seems more reasonable, if we had fewer of them, to lock up all the syphilitic subjects in order to banish an easier transmitted disease.

HUTCHINSON'S SUMMER ERUPTION.

Prof. Jarisch showed a case of this character to the Dermatological Gesellschaft, and added that this disease was not of recent date, although Bazin appears to have been the first to isolate it under the name of *Hydroa Vacciniforme* which Hutchinson later renamed *Summer Eruption*. The patient appeared to have both ears shrunken or eaten away, while the surface had a smooth blue coloured appearance with notches here and there making deep depressions. According to the history of the patient the progress of the disease stood still during the winter, but under the influence of the sun's rays in summer both ears became intensely red, inflamed, and swollen, forming nodules and vesicles, subsequently forming scabs that fell off leaving deep crater-like pits. The hands also bore testimony of a similar phenomenon as deep indentations and thickening are still prominently visible.

The Operating Theatres.

MIDDLESEX HOSPITAL.

ILIO-Psoas Abscess.—Mr. PEARCE GOULD operated on a woman, æt. 34, who had been admitted with a fluctuating swelling in the right iliac fossa, which had slowly grown during the previous twelve months. The tumour consisted of a superficial portion the size of a duck's egg bulging forwards above the outer part of the iliac crest. Deep in the iliac fossa fulness was detected extending back to the brim of the pelvis and towards the sacral promontory; fluid could be displaced between these two parts of the swelling. There was no extension of the abscess into the thigh, and no signs of disease of the spine, sacro-iliac joint, ilium, or pelvic organs, nor was there any evidence that pus had reached the iliac fossa, the pleura, the kidney, or the peri-cæcal peritoneum. Mr. Gould pointed out that the absence of the known signs of disease of the spine and sacro-iliac joint did not enable him to negative the existence of either of these diseases as the origin of the tubercular abscess before him. He opened the abscess by an incision two inches long into the superficial swelling parallel to and just above the front of the iliac crest. A large amount of very thick curdy pus escaped. He found that at the bottom of the superficial cavity there was an opening that just admitted his finger into the deeper abscess, which appeared to be behind the psoas muscle and extended to the sacro-iliac joint, the front of which was bare. With a flushing spoon he carefully and systematically removed the entire lining of the abscess, and after a prolonged flushing of the cavity with bichloride of mercury solution he wiped it out with antiseptic swabs and removed in so doing several portions of the scraped-off lining of the abscess which had not been brought away by the very free flushing. He then applied iodoform paste to the exposed tissues and closed the wound without drainage. Mr. Gould alluded to the importance of wiping out such cavities after even the most thorough flushing if the surgeon wished to make sure of removing all the tubercular tissue, upon such complete removal the success of the treatment depended. Although the sacro-iliac joint was exposed in the wall of the abscess it was not impossible, he thought, that the treatment adopted might be entirely successful; the issue would depend upon the extent and activity of the disease of that joint. Should the abscess refill, and it became plain that the disease in

the joint was active, he should propose to arthrectomise the joint in the way advocated by Mr. Golding Bird.

ST. THOMAS'S HOSPITAL.

GASTROSTOMY.—Mr. BATTLE operated on a man, set. 60, who had a malignant stricture of the lower part of the œsophagus from which he had been suffering for some six months. He was unable to swallow solid food of any kind, but could still swallow fluids; he did not suffer any pain, but was emaciating rapidly and losing strength. No bougie could be passed through the stricture. One had been passed on a former visit about a fortnight before. There were no signs of disease elsewhere, and the patient agreed to submit to operation after the nature of it had been explained to him. It was decided to perform the operation in two stages, and by a method which permitted of quick operation. The oblique incision was made in the usual situation parallel to the left lower ribs and deepened down to the rectus muscle, the fibres of which were separated, and the remainder of the incision continued in the longitudinal direction. The abdominal wall was unusually thick for a case of gastrostomy, as there had been comparatively little loss of the subcutaneous tissue. The stomach was easily found and drawn into the wound. The portion selected for the opening was carried to the extreme right of the oblique incision, and then two stitches passed through the peritoneum and walls of the stomach, one above and the other below, so as to shut off the peritoneal cavity. The highest point selected for the opening was drawn through a Senn's bone plate and transfixed with two hare-lip pins, which did not, however, enter the interior of the stomach. A trocar and cannula were then passed between the pins into the stomach, and on withdrawal of the trocar a number one catheter was introduced through the cannula into the stomach, and the cannula withdrawn over it. A stitch was then passed through part of the stomach wall, and the ends tied round the catheter. The external wound was closed with interrupted sutures, the bone plate being left across the upper part and at right angles to it. Cyanide gauze was applied to the wound, and a many-tailed bandage put on. The end of the catheter was plugged and brought into the cotton wool of the dressing. Two points, Mr. Battle said, were of importance in performing the operation: first of all, by going between the fibres of the rectus muscle, he hoped to obtain a kind of sphincter action; secondly, by carrying the opening as high up as possible, he hoped that further obstacles to the escape of gastric contents would be presented as the mouth into the stomach would be considerably higher than was usually the case after gastrostomy. The patient's great complaint after this operation is of the irritation caused by the escape of gastric juice, which produces troublesome eczema and much soreness for some distance round the opening.

It is not often that the Local Government Board has to deal with cases of cholera in England, but last week an official report reached the authorities that a steamship, the *Garlands*, had put into Holyhead harbour with several cases of cholera on board. Two of the crew had died from the disease during the voyage from the Black Sea to Constantinople. Dr. Thorne Thorne promptly despatched Dr. T. Thomson, one of the medical inspectors, to Holyhead, and after ample disinfection of the ship had been carried out, the *Garlands* was allowed to proceed to Barrow-in-Furness, where she will be closely watched by the local medical officers and the authorities of that port, in view of any outbreak of the disease.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 29, 1896.

THE DEATH OF PRINCE HENRY AND ITS LESSONS.

DURING the past week the news of the death of Prince Henry of Battenberg created a profound sensation among the inhabitants of his adopted country, Great Britain. It was known that the Prince had reached the scene of operations up country, and had witnessed the consummation of the bloodless campaign against King Premph of Ashanti. On January 10th a telegram was sent to England stating that Prince Henry was suffering from a slight attack of fever, and had gone back to the base of operations. Five days later a Renter's telegram stated that his temperature was lower after a restless night, and that he would continue his journey to the coast. On the 17th it was further announced that he had embarked on the cruiser *Blonde* for Madeira, and that, although weak, his symptoms were not grave. Three days later, however, he died at sea, and the cruiser *Blonde* put into Sierra Leone on Wednesday last in order to telegraph home. The sad news, it need hardly be said, caused the deepest consternation and grief in the Royal household. No words of ours can add to the widespread national sympathy which has been expressed with the calamity that has overtaken the Queen and the Princess Beatrice. At such a time of bereavement silence is often far more eloquent than speech. On

the other hand, from a medical point of view, many points naturally present themselves to our consideration, and it would be mere affectation to avoid their discussion because of the nature of the sad event to which they owe their present prominence. As to the course of the Prince's illness, everyone who is familiar with tropical sickness will recognise the fact that nothing is more common than for relapses to occur when a patient has been brought down to the coast or after he has got out to sea. Furthermore, it is a fact that strong persons succumb to tropical disease as readily as the weak. When we come to consider the nature of malaria itself, we are compelled to admit our almost complete ignorance upon many points of its etiology and pathology, as well as our inability to treat the condition with any certainty from a curative standpoint. Speaking generally, it seems clear that the group of acute specific fevers known as malarial are due to a poison that emanates from marshy lands, more especially in hot countries. This particular poison may be carried for long distances by the wind, but its progress may be stopped by such obstacles as a belt of trees, a broad sheet of water, or a chain of hills. The *materies morbi* is now generally regarded as being a protozoon, the *plasmodiaise malaricæ*, which was first demonstrated by Laveran in 1882. This parasite is found in the blood, where it invades and disintegrates the red blood cells, but its causal relationship to malaria has not yet been proved. If the protozoon flourish in damp districts, it seems likely that it may, in common with the micro-organisms of cholera and other specific affections, enter the body through the medium of drinking water. All that can be said at present on these and other points is that a great deal can be done in the way of prevention. The truth of that statement may be found in a comparison of two recent campaigns in malarial countries, namely, Madagascar and Ashanti. In Madagascar the French army was badly equipped from a medical point of view and the soldiers had to undergo great hardships and exposure in the dense tropical forests. As a result their ranks were simply decimated by malaria. In our own march to Ashanti, on the other hand every possible precaution was taken to secure the safety of our soldiers. The camps were prepared beforehand at certain intervals along the line of march, and the soldiers slept in huts raised several feet above the ground. In consequence of these measures the general health of our troops has been excellent. It has been elsewhere remarked that one good result that may accrue from the lamented death of Prince Henry is the more careful study that the subject of malaria will probably receive. Now that a fresh impetus has been given to the investigation of tropical disease by the appointment of special lecturers in some of our chief medical schools we may look for much information and valuable progress in that direction. One may confidently assume that the working out of knotty points in the diseases peculiar to the tropics would sooner or later throw many a sidelight on the numberless obscure problems that lie around us on every hand in our own northern clime.

A CRUCIAL POINT IN SANITARY PROGRESS.

Of late years London has been making great strides in the onward march of preventive medicine, a fact upon which the inhabitants of the greatest and richest city in the world may well be congratulated. In various ways, however, the metropolis is a laggard in the scientific race, and compares unfavourably with many provincial towns, such as, for instance, Newcastle and Glasgow. There can be little doubt that the lack of intelligent public interest has lain at the root of this lamentable backwardness in a matter so deeply affecting the welfare of the community as the administration of sanitary affairs. Until recently Londoners have been content to leave the management of their roads, of their water-supply, of their sanitation, of their Poor-law service, in the hands of local bodies, which were only too often corrupt nests of nepotism and jobbery. With the advent of the London County Council, however, and an awakening of general interest in municipal matters, the promise of a purer and a fairer future was gladly welcomed by the sanitary reformer. But the day of full salvation is not yet with us. In many of our metropolitan districts, rich and poor alike, the Vestrymen or Councillors are chosen by small hole and corner cliques, and are elected as local rulers and administrators of vast sums of money without even the formality of a public election. For such a travesty of representative local government the citizens have themselves to thank. The voters hold the key to the situation, and if they choose to organise their ranks, nothing would be easier than to return to the Vestries men of good standing and unblemished character, in whose hands the public weal would oust all mere party purposes and the sordid filching and diversion of the ratepayers' money, which is, perhaps, best described by the terse and expressive term "jobbery." Turning to details of practical health work, we are at once struck with the importance of the sanitary inspector, who is, as it were, the policeman of preventive medicine. As the servant, first of the medical officer and then of the Vestry or Council, it is his duty to investigate and to report upon the multifarious details that are brought within the purview of local health committees. Sanitary inspectors as a whole, we are glad to believe, constitute an honourable and useful body of public servants. On the other hand, it is matter of common knowledge that a certain number of them are unfit for their position, and may be regarded as inheriting the traditions of the bad old days of vestrydom. But, apart from the black sheep, it may be fairly questioned whether the whole position taken up by the sanitary inspectors does not require serious consideration. The claims of these subordinate officials, as it would appear from a perusal of the reports of their Association meetings, have grown until the Lilliputian body imagines itself nothing less than a giant of Brobdignag. The Sanitary Inspector, as pictured by the Association, is in future to become a kind of inspector, lawyer, medical officer of health, doctor, and engineer, who is to act under and report to the Vestry; to carry on his own scientific investigations; to be his own hygienic law-

giver; and to fulfil the office of guide, counsellor, and moving spirit generally in the public health administration of the parish to which he has been appointed. Without doubt, this aggressive attitude, so far as London is concerned, has been allowed to spring up by the apathy of the medical officers of health known as "half-time" men, who leave the main part of their public work to be discharged by their inspectors, while they themselves are engrossed by the busy cares of general medical practice. A case in point is to be found in the heart of London, where only a few months since the authorities of one of the most crowded districts chose a medical officer of health, who was permitted not only to carry on private practice, but to hold a similar "half-time" post in another metropolitan parish. And this arrangement, *mirabile dictu*, was sanctioned by the Local Government Board. Under such circumstances, it seems hardly possible that the medical officer of health can be otherwise than at the mercy of his inspectors, and it is a matter for congratulation that evil results are not more frequently heard of. During the past few weeks London has had an object-lesson as to the possibilities of the case in the person of a sub-inspector of a Southern district. This official was known to have written to a house-agent, asking for full particulars as to certain houses in the parish and what commission on sale the agent was prepared to pay. He was subsequently requested to resign by the health committee of his Vestry, which he did. Shortly afterwards he brought forward a charge implicating his former chief inspector in offences of a similar nature. The chief inspector was exonerated by his Vestry, but the matter appears to us none the less imperatively to demand a further inquiry by the Local Government Board into the whole circumstances of the case. 'In no other way can the confidence of the public and of the medical profession be restored as regards the purity of local sanitary administration. The fact that the chief official in question is President of the Sanitary Inspectors' Association makes it all the more necessary that a searching departmental inquiry should be undertaken forthwith. In making that demand we confidently assume that the main body of the inspectors, upon whose honesty and good faith we rely implicitly, will be with us in seeking to clear up the grave stigma which has been cast upon them in the person of their President. In the interests of the future of the public health service we suggest that such an inquiry might conveniently be extended or supplemented so as to take into consideration the position and powers of what we have ventured to call our "sanitary police." Our own view on the question is simple, and has been more than once emphatically recorded in these columns. To put the matter in a nutshell, it is that the choice and control of his subordinate sanitary inspectors should be centred absolutely in the Medical Officer of Health. Past experience has proved over and over again that of all men the sanitary inspector is best fitted to serve two masters.

INFANT MORTALITY.

THE great waste of infant life which at present obtains in the Metropolis and other parts of the kingdom is a scandal and a disgrace to our civilisation. To say that such waste is unpreventable is simply to argue against the logic of facts. That it can and should be prevented is indisputable, and no sensible person who has paid any attention to the subject can deny that if the Legislature were to take it properly in hand a better order of things could soon be made to prevail. There are societies at work which have for their object the protection of little children against cruelty, and it seems somewhat curious that they have not included in the sphere of their usefulness some measures for the prevention of the causes which lead to the enormous mortality among infants. Surely the officers of these societies must come in contact with the many deleterious influences concerned in the production of the excessive infant death-rate. Who, better than they, would be in a position to see the evils which prevail, or better qualified to draw attention to them in the proper quarters? As a matter of fact, this question of infant mortality is becoming more and more serious every year. During last year no less than 22,000 children under twelve months of age died in London alone. The total number of deaths in the metropolis for the same period was 86,940; in other words, upwards of 25 per cent. of the death-rate occurred among children who had not passed the first year of their life. The seriousness of this position of affairs, in our opinion, calls for a public inquiry. The matter should be brought under the notice of Parliament early in the coming session, and a Royal Commission asked for with a view to ascertaining all the evidence in connection therewith, and the passing of some legislative enactment by which this waste of life would be much curtailed. Within the past week or so two important references have been made to this subject. Dr. Rabagliati pointed out in a public lecture delivered in Bradford that in that town the birth-rate was lower than in other Yorkshire towns, and that of all the children born in Bradford in 1894 one in five died under the age of one year. These facts, were so remarkable that he could not avoid asking the question, "Is this civilisation; can it be that we who pride ourselves on being in the van of civilisation can be so reckless of our children's lives that we lose one-fifth of those born before they are a year old?" The other reference to the subject occurs in the report just issued, of Dr. Waldo, Medical Officer of Health for St. George's, Southwark. He points out that the highest infant mortality is in the Strand, Holborn, St. George's in the East, St. George's (Southwark), Limehouse and Clerkenwell, where one out of every five children born dies before it is twelve months old. This statement it will be seen represents exactly the condition of affairs which prevails at Bradford. In Dr. Waldo's opinion the causes of infant deaths in his district are: (1) Bad environment, such as insanitary conditions, overcrowding, and absence of parks and open spaces; (2) improper and insufficient food; (3) mismanagement by mothers

through ignorance ; (4) early marriages ; (5) debility of mothers ; (6) maternal neglect, due to mothers being more or less employed away from home in factories and workshops ; (7) the use of opiates, usually in the form of patent medicines, given to lull or satisfy the hunger of the child. Two important suggestions are made for the remedying in some degree of these defects. The first is the establishment of "open breathing spaces," and secondly "crèches," or day nurseries for the better protection of infants during the hours that they are deprived of the maternal care. This latter suggestion introduces an important question. It would be well if every parish had its crèche, in the same way as there is attached to every large union an infirmary for the treatment of sick paupers. The union crèche might be an institution provided out of the rates—but partly self-supporting by the sums charged for the care of the children. Under this plan there would be the certainty that the children would be properly looked after, and a marked diminution in the infant mortality rate would follow as a matter of course.

Notes on Current Topics.

Diphtheria Bacilli and Their Products.

A PAPER read by Drs. Kanthack and Stephens at the last meeting of the Pathological Society of London throws a new light on the production of the diphtheria toxin within the living organism. On the strength of the very interesting researches carried out by Dr. Sidney Martin it was believed that the bacillus developed exclusively in the false membranes which form in the throat, and the presence of poisonous albumoses in the viscera was explained on the assumption of the elaboration by the diphtheria bacillus, located in the throat, of a ferment or ferments which acted on the tissue proteid and converted it into the albumoses aforesaid. The more recent investigations of Drs. Kanthack and Stephens confirm the observations of others that, as a matter of fact, the bacillus is often to be found in the organs, especially in the lungs and spleen. Their investigations, it is true, were carried out on the subjects of fatal diphtheria, with laryngeal complications, and this may possibly account for the presence of the bacillus in the lungs. Broncho-pneumonia, it is well known, is a fairly frequent and always dangerous complication of diphtheria, and in the light of this discovery of the ubiquity of the pathogenic organism it is highly probable that the pulmonary disease is really of diphtheritic origin. It is possibly only in the most severe cases that the bacillus breaks bounds and wanders far and wide through the tissues and enters the lymphatic and blood circulations, but this is a point which demands further inquiry. The fact has an important clinical and therapeutical bearing, because it follows that the quantity of toxin requiring to be neutralised is far greater than has hitherto been supposed, and this points to the desirability of employing antitoxin freely in large doses in all cases which manifest any degree of severity.

The Bacteriological Diphtheria Test.

THE experiment now being carried out in Marylebone of furnishing apparatus and opportunity for free bacteriological examination in doubtful diphtheria will be watched with much interest by all who are interested in public health progress. Its results during the quarter have been as follows :—Twenty-one cases of presumed diphtheria have been examined, and of these 11, or rather more than half, showed the typical microphyte. The actual number of cases of diphtheria notified during the period in question was 75, of which number 41 were removed to hospital. These figures show a marked increase over the corresponding period of 1894, when 67 cases were officially reported. In view of the alarming spread of this fatal, but quite preventable disease, Dr. Wynter Blyth is to be congratulated on his action in affording medical men in his district an opportunity of arriving at an absolute and early diagnosis in doubtful cases of sore throat.

Remarkable Death of a Medical Practitioner.

THE death of a medical practitioner, Mr. John Robinson, of Bridlington Quay, Yorkshire, last week under peculiar circumstances has been largely commented on in the local press. Briefly, the facts are as follows :—Mr. Robinson had under his care a young man suffering from some slight ailment for whom he prescribed a bottle of medicine. After one dose, however, owing to the "agonising effects" caused, the patient refused to take any more of the mixture. This surprised his medical attendant, but it led to the latter taking the bottle away and promising to send another mixture of less strength than the first. However, the same effects were produced in the patient after a single dose of the second medicine, and again he declined to take any more. This having been brought under the notice of Mr. Robinson, he visited the patient, and stated that the prescription from which the medicine had been prepared was one that he was accustomed to use every day, and that he himself would not object to swallowing the whole of the contents of the bottle at once. Suiting the action to his word, he called for some water and proceeded to pour out a large dose of the mixture, which he promptly swallowed. Soon afterwards he began to feel ill. He accordingly proceeded home at once, and sent for two *confrères*. Everything that was possible was done for him ; but the symptoms of poisoning rapidly developed, and death took place two hours later. His belief, at first, was that the medicine had contained a strong dose of tincture of ginger, but before he died he expressed the opinion that aconite had somehow been dispensed by mistake in the mixture. Mr. Robinson had been forty years in practice in Bridlington, and had reached the age of sixty-four.

The Sale of Poisonous Fly-Papers.

THE enterprise and activity of the Pharmaceutical Society of Great Britain in prosecuting unlicensed sellers of poisonous preparations has very properly been extended in the direction of bringing actions against grocers who deal in poisonous fly-papers. A case of this description was heard last week in the

Bloomsbury County Court. The action was brought in respect to the sale of twenty-five fly-papers, the composition of which on analysis showed an average of eight grains of arsenic in each. Dr. Thomas Stevenson, analyst to the Home Office, was called for the prosecution, and agreed with the analysis that had been made; and he also pointed out that two grains of arsenic was a fatal dose for an adult. The only defence made was that wall-papers, posters, and various fabrics contained arsenic. But the judge declined to admit this evidence, and gave judgment for the plaintiffs, namely, £5 and costs. In regard to poisonous fly-papers, the use to which they are put for suicidal purposes has been repeatedly brought under public notice, and it is, therefore, highly essential that their sale should be restricted, at all events to those tradesmen whose business it is to deal in drugs.

The Direct Representation for Ireland in the General Medical Council.

We understand that it has been arranged that notice of the forthcoming election shall be issued on the 1st of February—that the Rescript shall be presented on the 12th—that the nominations of candidates shall be handed in, at the latest, on the 15th—that the voting shall take place between the 20th and 27th, and that the result will be declared on the 2nd of March. Meanwhile the manœuvring of parties is interesting. Mr. Thomson, Dr. Jacob, and Professor Cuming are, at present, apparently at rest, but no doubt every nerve is being strained to exercise private influence on voters. Dr. MacDonnell's party, on the other hand, are making herculean efforts to get other candidates out of the field, which, indeed, it is wise of them to do. With this purpose they are flooding the newspapers with adjurations to the "provincial" candidates (in which category they include only Dr. MacDonnell, Professor Cuming, and Dr. Greene), to take a preliminary plebiscite for the purpose of deciding who shall withdraw and who shall go to the poll. It is to be supposed that they know pretty well that Professor Cuming, being pledged to the Belfast School, cannot withdraw, and their plebiscite could, therefore, only result in a poll between their own candidate, Dr. MacDonnell, and Dr. Greene, in which, without a shadow of doubt, Dr. MacDonnell would come out with a lead, thus acquiring all Dr. Greene's votes without much trouble. We desire to speak with every respect of the anxiety of certain of the country practitioners to send one of themselves to the General Medical Council, but if this aspiration is only a sentiment it seems unwise to lose the game for the sake of gratifying it. A provincial is, in respect of that fact, neither better nor worse than a townsman. What would be the fate of a government which selected its ministers, not for special aptitude or experience, but because they lived in Birmingham, or Cork, or Glasgow? It is, thus, neither a recommendation nor a detraction that a candidate lives in any particular place, the only question to consider is whether he is the very best person who can be had to represent the special interests of the country doctor. If he is not the right

man he cannot be so even if he resided in the moon. Some may think that it would be better to have a mediocre provincialist than a specially qualified townsman, and then the question arises whether the mediocrity can be secured by any means. If it appears that he cannot succeed what is the sense of voting for him, and thus placing the coveted position in the hands of the townsman whom it is desired to keep out? The provincial idea is an excellent sentiment upon which it is not wise to wreck the cause.

The Weather, Influenza, and Disease.

It is hardly realised, as yet, how seriously the repeated attacks of influenza during the last six years may have modified the incidence of disease for that period. At no other period of the world's history, and we can go as far back as 1173 in this respect, have so many attacks of this malady followed each other in such quick succession. If we remember that the poison of influenza acts vigorously on nearly all the systems of the body, we may easily conclude that the constantly recurring outbreaks which have scourged this country in common with most of the civilised countries of the globe must have had a great influence on the public health. In a paper read at the Royal Society of Edinburgh on Monday, last week, Dr. Lockhart Gillespie summarised the results of an inquiry into the effect of the weather and of influenza on the admissions into the medical wards of the Edinburgh Royal Infirmary. He found that the type of weather, *i. e.*, cyclonic or anti-cyclonic, had had a very considerable influence on the admissions of certain diseases. Patients with respiratory disorders were admitted in greater numbers during cyclonic weather, although those suffering from acute pneumonia were in the majority when the conditions were anti-cyclonic. Cases of acute rheumatism, chorea, and digestive diseases were more numerous in anti-cyclonic weather. With regard to influenza, he pointed out that this scourge had been epidemic in Edinburgh during 68 weeks in the last six years, or one week in every four and a half. From the infirmary records it was clear that coincident with the onset of the attacks a great increase occurred in the number of respiratory cases admitted, especially in cases of pneumonia, but that the figures for the periods following the epidemics were almost of greater importance, showing, as they did, a very considerable increase in the number of heart and nervous cases. The importance of this latter fact lay in the insidious onset of these sequelæ, generally after the patient had left the doctor's hands for the original malady, if, indeed, he had ever been treated for it. An examination into the weather conditions before and during the epidemic periods showed that the six attacks, as a rule, had been preceded by cyclonic, cold, and wet weather, had commenced in anti-cyclonic, cold, and dry weather, had persisted in weather which was normal for the time of the year, and had declined under cyclonic, wet, and warmer conditions. No suggestion was made that the type of weather had anything more to do with the onset of the malady in epidemic form than to afford facilities for its rapid

spread. The four previous attacks for 1848-49, 1851, 1855, 1857-58, exhibited the same peculiarities with regard to the nature of the cases admitted into the infirmary, the percentages to the total admissions being in all these instances remarkably similar.

Death from Accident or from Fatty Degeneration of the Heart?

A CASE which presents some very interesting medical points was decided in the Scottish Court of Session last week. A man, aged about 45, who had previously enjoyed excellent health, fell off the bridge of a steamer, a distance of about 9 feet. He was a stout man, of about 15 stone. When picked up he was found to be insensible. On recovering consciousness, he began to spit blood, and later, he was found to have a broken rib. Subcutaneous emphysema made its appearance a day or two afterwards. Five days after the accident he died suddenly with symptoms which pointed rather to asphyxia than to syncope. At a post-mortem examination the broken rib, with some congestion of the lung, was discovered—and a fatty heart. A certificate was granted to the effect that the death was due to syncope from the effects of fatty degeneration of the heart accelerated by an accident. The deceased had been insured in the Scottish Accident Insurance Company for £1,000. On applying for payment of this sum his trustees were met with a refusal, the company alleging that one of the terms of the policy, to the effect that death by disease, if accelerated by an accident, rendered it void, precluded the trustees from recovering the sum. At the trial the onus was laid on the company to prove that the man did die of a fattily degenerated heart, the other side suggesting that the heart was only infiltrated with fat, as was to be expected in a stout man of that age, and that his active habits and uniform health precluded or rendered very improbable the pre-existence of such an extreme degree of fatty degeneration as was described. A great point was made of the difficulty in diagnosing between fatty degeneration and infiltration without the aid of the microscope, which had not been used in this case. Judgment was given against the Insurance Company, with expenses. The point which seemed to strike the judge more than anything else was the question, where insurance companies would stop under the condition inserted in their policies, which has been mentioned above. It certainly should be better known that in the policies of some insurance offices such conditions are present, for there are few men above forty who have not got some little thing wrong with them, which might be held to precipitate the fatal result after an accident, and which might be alleged to be the actual cause of death. No one would care to insure their lives against accident when they knew that there was such a chance of expensive litigation on the flimsiest pretexts after death.

The Case of Mr. R. B. Anderson.

THE Civil Rights Defence Committee are still working hard to obtain justice for Mr. R. B. Anderson.

It is a matter of surprise to us that the public have hitherto paid so little attention to this case. The principles involved, for which Mr. Anderson and those associated with him have for upwards of four years been so pluckily striving, are those in which every person in the kingdom has an interest. No one who has taken the trouble to read the facts of the case—and they are eminently worth perusal—can help being astounded at the illegal persecution to which Mr. Anderson was compelled to submit. However, we are glad to see that the apathy in this connection is less than it was, and that public bodies are beginning to realise the greatness of the issues at stake. The Civil Rights Defence Committee, with Mr. Anderson, deserve every encouragement in their arduous crusade; but it may be pointed out that practical assistance in the form of contributions to the General Fund is urgently needed. Within the past week a donation of £10 has been received from the Barbadoes branch of the British Medical Association, and the medical men of Exeter have subscribed upwards of £28. These examples might be emulated by bodies of medical men throughout the country. It is only by united action of this kind that the victory can be won.

The British Balneological Association.

THE British Balneological Association held its inaugural meeting at Limmer's Hotel on the 22nd inst. The Association came into existence in November last, and everything, so far, points to the fact that a useful and prosperous career lies before it. The inaugural address was to have been delivered by Dr. W. M. Ord, but in his unavoidable absence this duty was discharged by Dr. Symes Thompson. A discussion followed the address, no doubt for the useful purpose of showing more plainly the objects and aims of the Association. If the Association succeeds in impressing upon the medical profession and upon the public in the United Kingdom that many of our spas possess just as much therapeutic value as those to be found abroad, a great point will have been gained. The business of "working" these health resorts has never been properly understood in this country, but a great improvement has recently taken place in this regard, and, with the events of the past few weeks in view, the opportunity is a good one for patriotic English people in search of health to elect to remain in their own country, and visit the spas over which their own countrymen preside.

Alterations in the Edinburgh M. D.

READERS may be reminded that the new regulations as regards the degree of Doctor in Medicine are now in force. First and foremost, the government stamp of ten pounds has been repealed, the late liberal administration having decreed the repeal of that particular form of taxation upon knowledge. Further, those who have passed the M.B. examination under the regulations in force before 5th August, 1892, may now proceed to the degree of Doctor of Medicine under the old or under the new regulations. The old regulations required the candidate to send in a thesis, and to have passed a preliminary examination in *three* of the

following subjects:—French, German, Higher Mathematics, Natural Philosophy, Greek, Logic, and Moral Philosophy. Two of these must be Greek, and either Logic or Moral Philosophy. Under the new regulations, the candidate for the M.D. may pass a further examination in Clinical Medicine, and thus escape the ordeal of furnishing up Greek, Logic, or Moral Philosophy. There can be no doubt that a great many men in busy practice have failed to take their degree of "Doctor" in the University because of the bugbear of reading up one of the necessary preliminary subjects. To such men a revision of their clinical medicine would not only be a pleasure but also a valuable practical means of testing their experience and of bringing them in touch with the most recent advances of professional knowledge. The University of Edinburgh appears to be acting wisely in making the path of its alumni as smooth as may be from starting point to goal. The unavoidable obstacles are quite hard enough in themselves without adding to their number. The Senate would do well, as a next step, to revise and lessen fees, which have increased considerably of late years.

Emergency War Hospitals.

ACCORDING to the *Leeds Mercury*, several of the Hull medical charities have received communications from York, asking whether beds could be provided at the institutions for the use of those engaged in the defence of the Humber in time of war. The Hull Royal Infirmary replied in the negative, as they felt they had a duty to perform to the sick and hurt poor that must not be neglected. At the same time, they intimated their willingness to assist to the utmost if occasion should arise. It is further stated that the Infirmary people were of opinion that many buildings might be utilised in time of need; while the charities would continue to fulfil the mission for which they were established. With the view thus expressed we certainly agree. We fail to see the slightest necessity for disorganising the ordinary public hospital service in time of war. Nothing could be easier than to adapt existing buildings, such as churches, factories, domestic houses, or farm buildings, so as to convert them into serviceable hospitals. Moreover, in the present day many alternative temporary structures are available. Tents, ambulance waggons, huts of wood and iron, and ships could be provided within the space of a few days to meet every possible demand. The whole question thus raised appears to be of too puerile a nature to have come from the War Office authorities.

Female Medical Education in India.

THE cause of the lady doctors in India is being carried on with an energy that must sooner or later achieve success. Some time since the Campbell Medical School at Calcutta was thrown open to native students. The women who formed the class lived for the most part at a distance from the colleges, and had to be brought to and fro every day in native omnibuses. In spite of these and other drawbacks, however, the movement continued to flourish. It has now received a great impetus in the shape of an hostel,

which has been built as a residence for students in term time. The native attitude towards the scheme may be inferred from the fact that the Nawab Begum of Murshidabad contributed 25,000 rupees to the fund. The new building bears the name of Lady Elliott, who has had a large practical share in the organisation of women's work in India.

Foreign Medical Men in France.

THE medical profession in France has its trials and difficulties, similarly as is the case in other countries, but the fact which appears chiefly to be disturbing the minds of members of the profession there at the present moment is the invasion of the country by foreign medical men. In a recent number of the *Journal de Med. de Paris* a most doleful article appeared lamenting this state of things. The writer points out that in former years foreign medical students simply came to France for their education, and afterwards returned to their own country to practise. But, latterly, this has not been the case. The foreign students have liked France so well that they have made up their minds to remain. According to the last official medical census, a large number of foreign medical men are now practising in Paris, that is to say about 521, which represents more than one sixth of the total number of medical men, namely 2,992, with whom Paris is provided. The foreign residents in Paris have been estimated at 180,000; the proportion of foreign medical men to foreign population is about 3 to 1,000, that of French practitioners to the native population, properly speaking, is only 1 to 1,000. But this foreign medical element is beginning to invade the rural districts in France, a fact which is causing still further dismay to the French medical profession. After all, perhaps, our *confrères* across the Channel may have some grounds of complaint in this respect.

A Central Hospital Board for London.

ALTHOUGH there was nothing especially new in the paper read by Colonel Montifore last week before a large meeting of the Charity Organisation Society, upon the subject of the organisation of a central hospital board for London, yet all must admit that good can only come from pressing forward the scheme upon every available opportunity. There can be no doubt whatever that if such a board were to be established its field for usefulness would be a wide one. The philanthropic public would gain by its ministrations and so would the *bona fide* hospital patient and the medical profession. Of course, it would meet with some opposition on the part of those whose interests it would affect, but this would only be in the natural order of things. Every great reform has been opposed, and a scheme such as that under discussion would be of so reforming a nature that more or less opposition against it must from the first be anticipated. The question is decidedly a good one for the Charity Organisation Society to have raised, and we trust that they will make every effort to keep it before the public and "peg away" at it until some really practical result has been achieved. So far as the medical pro-

session is concerned there is no doubt that general support would be accorded the scheme.

Double Consciousness.

We are reminded now and then by facts that come under our observation that Nature comprises forces and conditions of which we have as yet but little, if any, conception. The last new discovery that certain rays can penetrate the proverbial deal plank is a philosophical trifle compared to the curious mental conditions which are occasionally revealed to us in the humblest of individuals, to explain which the medical scientist is fain to take refuge in the most hare-brained hypotheses, which, after all, only make confusion worse confounded. At last week's meeting of the Clinical Society, a distinguished suburban practitioner, whose name we withhold in order not to afford any clue to the identity of the patient, showed a girl, 12 years of age, who exhibited in the most complete and indubitable form the condition known as "dual existence" or "double consciousness." Last year, after a severe illness which was diagnosed to be meningitis, she became subject to temporary attacks of unconsciousness, on awakening from which she appeared in an entirely different character. In her normal condition she could read and write and speak fluently and with comparative correctness. In the altered mental condition following the attack she loses all memory for ordinary events, though she can recall things that have taken place during previous attacks. So complete is this alteration of memory that at first she was unable to remember even her own name or to identify herself or her parents. By patient training in the abnormal condition she has been enabled to give things their names, though she still preserves a baby fashion of pronouncing. She sometimes remains in the abnormal condition for days together and the change to her real self takes place suddenly without exciting surprise or dismay, and she forthwith resumes possession of her memory for events of her ordinary life to the exclusion of those which have transpired during the abnormal state. During the last month or so she appears to have entered on a new phase, for, after a mental blank of a fortnight's duration, she awakened completely oblivious of all that has happened since June, 1895, and she alludes to events that took place just anterior to that date, as though they were of quite recent occurrence; in fact, she is living mentally in July, 1895. These cases, though rare, are of course not unfrequently met with, and they have been carefully studied, especially in France, where women appear more prone to neurotic manifestations. The hypothesis that finds most favour is that the two halves of the brain do not work in unison, in other words, that there has been some interference with the connections which, in the ordinary normal being, make of a wonderfully composite organ like the brain one organic whole. Sometimes one part of the brain and sometimes the other takes possession of the field of psychical activity, and, as each part works to the exclusion of the other, we get the Dr Jekyll and Mr. Hyde transformations. Verily, truth is stranger than fiction, and it seems highly probable

that Robert Louis Stevenson, in writing his enthralling story, must have taken for his theme some such case as the one which we have briefly described.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

THE FATAL ACCIDENT INQUIRY ACT FOR SCOTLAND.—At the time that this bill was introduced by the late administration, we suggested that it would serve no useful purpose. Sufficient time has now elapsed since it became law to judge of its usefulness. On all hands it is regarded as an intolerable nuisance. The skill of our legislators in drawing up bills which do not act as they were meant to act is proverbial, but it is still more marvellous in this case, as the bill was introduced by the then Law officers for Scotland. What they intended it to do is not quite clear, what it does do is clearer, and that is *nil*. The different sheriffs who have conducted inquiries into fatal accidents, as provided for by the statute, can find no authority in it to enable the jury to express any opinion in the matter except the bare and actual cause of death; no rider of any description seems to be allowable. Consequently, a court is summoned, considerable expense incurred, in order that a jury may have the pleasure of saying that John Jones, *say*, died from an accident at a certain place and time, a thing which everyone knew very well before. Even the cause of the accident, it seems, cannot be investigated. Such an inquiry would appear to be quite superfluous, and, at any rate, of no use in medico-legal cases, which would have to be begun from the beginning in another court.

A PARTIALITY FOR HIGH MEAT.—There is no accounting for tastes, and to some, meat which is tainted may be more acceptable to the palate than when fresh. The authorities of Dollar would appear to have strong digestions and an excess of hydrochloric acid in their gastric juice. A report by the local sanitary inspector, to the effect that he had seized some unwholesome meat in two butchers' shops in the burgh, was received by the Burgh Commissioners with a great show of indignation. The inspector stated that the meat was in a very putrid condition, pale, wet, greenish in parts, and with a very bad smell. The Provost corroborated these statements. A majority of the Commission, however, thought that it was a mean thing for the inspector to investigate the condition of the meat without first giving notice beforehand to the butchers. One member remarked that "putrid meat was not bad meat!" It appears that these same butchers have been repeatedly warned already, but the Commissioners refused to prosecute. A very bad point in the inspector's report is the statement that the worst pieces of the meat were being used for mincing purposes. We do not envy the people of Dollar their meat, and they would be wise if they avoided minced meat in the future, until what time their worthy commissioners have recovered a proper sense of their duties, or made way for others to whom putrid meat is putrid and disagreeable.

PRESENTATION TO SIR ARTHUR MITCHELL.—Sir Arthur Mitchell, K.C.B., M.D., M.A., LL.D., was presented with his portrait, painted by Sir George Reid, on the occasion of his retirement from the Scottish Lunacy Board. Lord Kinnear presided at the meeting, and, in making the presentation, referred to Sir Arthur's long services in connection with the Lunacy Board, and to the admirable tact, judgment, good sense, and kind feeling which he had always exhibited; to his services in other branches of science; and to wish him health and happiness in his retirement.—Sir Arthur Mitchell, in reply, said that his life had been full of hard, earnest work. He thought that he had had some success, and it gave him pleasure to think how abundantly he had been helped. Of the colleagues with whom he began his lunacy work not one now remained: they had all gone into the world of light. He said nothing of the insane, except that all of them had a fast friend in him. His official work was ended. As regarded it, he had reached old age, but he was not yet conscious of decrepitude. He hoped there was still some work in him, and he meant to do it. In addition to the portrait, Lady Mitchell was presented with 50 guineas to

buy a souvenir of the occasion, while the balance of the subscriptions, probably about £190, was handed to Sir Arthur Mitchell for the purchase of books to add to his library.

THE INFECTIOUS DISEASES HOSPITAL QUESTION.—The Corporation of Leith intend to appeal to the House of Lords against the decision of the Court of Session anent the erection of a hospital by the Edinburgh authorities in the burgh, a decision which was given in these columns two weeks ago.

SIR DOUGLAS MACLAGAN AND THE PRISON COMMISSION FOR SCOTLAND.—We understand that Sir Douglas MacLagan has tendered his resignation of the offices held by him under the Prison Commissioners. The resignation has been accepted by Lord Balfour of Burleigh, with an expression of his Lordship's regret at the severance of Sir Douglas MacLagan's long connection with the Prisons Department in Scotland. Sir Douglas succeeded the late Sir Robert Christison in the post of visiting physician to Perth General Prison in the year 1877, and since all the prisons in Scotland came under the charge of the Prison Commissioners in 1878 he has acted as their medical adviser.

EXAMINATION PAPERS FOR THE DIPLOMA IN PUBLIC HEALTH AT THE UNIVERSITIES OF OXFORD, CAMBRIDGE, DURHAM, AND VICTORIA. AND THE JOINT BOARD OF ENGLAND. (a)

(Continued from page 95.)

VICTORIA,* JULY 17TH, 1895.—PART I.

Sanitary Appliances, &c.

1. In a town of 100,000 inhabitants there are 2,600 deaths per annum, of which 350 were ascribed to Diseases of the Respiratory Organs, 250 to Phthisis, 100 to Diarrhoea, 100 to Convulsions, 50 to Enteric Fever, and 5 to Alcoholism.

Point out any deviation from the average, and any possible sources of fallacy in these figures.

2. Describe the steps to be taken in the course of an undertaking for the supply of water to an urban population, and state the conditions that must be fulfilled in any such supply.

3. Enumerate the provisions of the Public Health (Amendment) Act, 1891, as to the disposal of all kinds of refuse of towns.

4. What are the causes of dampness in houses? What are the regulations of the Model Bye-laws of the Local Government Board, with respect to the thickness of walls and the means of keeping them dry?

5. What forms of Hospital are best adapted for the isolation of infectious disease for towns of 20,000 inhabitants? State in detail the requirements of such Hospitals, and the regulations by which they should be managed.

* This paper should have been given on page 95. The Chemistry paper our correspondent has been unable to obtain.

OXFORD, NOVEMBER 26TH, 1895.—PART II.

No. I.—Pathology and Bacteriology.

1. The following terms have been used by writers on Bacteriology; explain each of them fully:—(a) "Anaerobe"; (b) "Facultative parasite"; (c) "Obligate Saprophyte"; (d) "Leptothrix"; (e) Staphylococcus; (f) Plate-culture.

2. Give an account of the method which ought to be followed in the investigation of the bacterial origin of any disease or group of symptoms.

3. Give a short account of the treatment of diphtheria with antitoxic serum.

4. What are the usual incubation period of—(a) Small-pox; (b) Scarletina, and (c) Measles? What precautions must be kept in mind in certifying in respect of each of these diseases that a dwelling is free from infection or contagion?

5. Give two examples of diseases believed to be "water-borne." In respect of one of these, state fully the ground on which this belief is founded. How do the facts referred to bear on the prophylactic measures to be adopted?

(a) Examination for the Degree of Bachelor in Hygiene, and for the Diploma in Public Health (D.P.H.) Durham.

6. Give a short account of Anthrax and of the micro-organisms associated with the disease, giving special attention to those points that relate to the aetiology and spread of the disease.

Not more than five questions to be answered.

Practical Bacteriology.

Examine and describe the growth in this test tube.

Make a microscopic preparation of the growth, examine it carefully, and give a short description of the organism or organisms present, stain either by Gram's method or with methylene blue. *Vicia* twenty minutes.

(This paper was not printed.)

CAMBRIDGE, TUESDAY, OCTOBER 1st, 1895.

(No written paper.)

Practical Bacteriology.

1. Name the objects under the microscope 1 to 5.
2. Examine the plate cultivations provided, and prepare cover-glass specimens from any of the colonies of micro-organisms which you may be able to recognise. Label your preparations, and draw and describe a rough sketch of the colonies from which they are derived.

3. From a mixture of micro-organisms in the tube provided you are required to make cover-glass preparations and describe the peculiarities of the organisms present, and to prepare a gelatine and agar plate for the purpose of separating the micro-organisms. With each plate leave directions as to its after-treatment.

4. Make preparations of, and write a report upon, the microscopic appearance of the sample of sputum provided.

DURHAM, TUESDAY, APRIL 16TH, 1895.

No. II.—Comparative Pathology.

1. Describe the structure of the *Trichina Spiralis*. Give the life history of this parasite, and point out how man may become infected by it.

2. Describe fully how you would obtain and make a bacteriological Examination of a piece of membrane from the throat of a person who is suspected to be suffering from Diphtheria. What results would lead you to conclude that the case was one of true Diphtheria?

3. Give the characters of the *Plasmodium Malariae*. How would you demonstrate its presence in the blood of a man suffering from malarial fever?

4. Give an account of how you would examine a filter, so as to test its efficiency in removing bacteria from the water passing through it.

5. Describe the Bacillus of Tetanus. How would you stain it to show the spore most clearly? Where are the bacilli most frequently found, and what conditions favour their growth in the body?

6. How would you examine a sample of milk for tubercle bacilli?

Practical Bacteriology.

1. Stain section C so as to show the bacteria in the tissues. Draw, describe, and identify what you find in the specimen.

2. Demonstrate to the examiner how you would obtain pure cultivations of each of the six different kinds of bacteria which are contained in a sample of water B.

3. Describe and identify specimens A and D.

4. Demonstrate to the examiner how you would make a bacteriological examination of the air of the laboratory.

CONJOINT BOARD OF ENGLAND, JULY 3RD, 1895.

Bacteriology.

(No written paper.)

Microscopical Work.

The tubes A containing agar agar,
" B " gelatine,
" C " broth,
" D " milk,

have all been inoculated with one organism.

Examine, make preparations of, describe, and name the organism. Mention the facts which influenced your opinion.

The tubes E containing agar agar,

The tubes F containing gelatine,
 " G " " broth,
 " D " " milk,

have also been inoculated with one organism. Examine, make preparations of, describe, and name the organism. Mention the facts which influenced your opinion.

[N.B. Do not taste the contents of any of the tubes.]

VOLUNTEER MEDICAL ORGANISATION.

THE report of the sub-committee appointed by the Council of the Volunteer Medical Association, and consisting of Surgeon-Lieutenant-Colonel Baines, V.D., Surgeon-Captain Squires, Surgeon-Lieutenant Fletcher, and Surgeon-Major Watson, V.D., secretary, has unanimously expressed the opinion that the departmental, as distinguished from the regimental, aid should be delegated to a departmental corps, and that all bearer companies should be specially recruited, uniformed, and administered as laid down in the Regulations for Volunteer Medical Staff Corps, and that they should be styled bearer companies, V.M.S.C., but that the existing regulations for regimental aid are sufficient and should not be interfered with, all that is required being to bring it into touch with headquarters and to provide for its efficient inspection. The Volunteer Medical Service, being the junior branch of the Medical Department of Her Majesty's army, is under the Director-General as the responsible head of the Department. The committee considers that the gap between the Army Medical Department and the Volunteer Medical Service is too wide, and suggests (1) that a medical officer with administrative rank should be attached to the headquarters of the Army Medical Department as responsible head of the Volunteer Medical Service, and (2) that in each district command a Volunteer medical officer should be appointed by selection from the senior medical officers of the district, and preferably for a limited period, by the Director-General as Volunteer principal medical officer of the district, with administrative rank.

With regard to executive officers the committee express the following opinion:—

Brigade-Surgeons-Lieutenant-Colonel: While this rank should be open to all medical officers of the Volunteer force who by length of service or other merit should have deserved it, it should not necessarily attach to the senior medical officer of an infantry brigade, as it does at present. **Surgeon-Lieutenant-Colonel:** In the regulations for promotion to this rank no changes are suggested. **Surgeon-Major:** The length of service required for promotion to this rank should, with certain conditions, be somewhat reduced in the case of an officer commanding a bearer company. **Surgeon-Captain and Surgeon-Lieutenant:** No suggestions are offered with regard to the present regulations as to these appointments. **Regimental Medical Officers generally:** Regimental medical officers should never be detached from their corps for other duty, except under the circumstances when more medical officers than are necessary for the work of that unit are present, in which case the senior medical officer of the brigade, with the approval of the commanding officer, may utilise the services of such additional officers as he may require. The committee are unanimously of opinion that, under no circumstances whatever, should regimental bearers ever be detached from their regiments.

Regimental Stretcher-bearers: There is a tendency to forget that the duties of a Volunteer regimental bearer are entirely secondary to his duties in his company ranks. They should never be withdrawn from the ranks unnecessarily. Stretcher drill should never take place during a battalion drill, and the inspection of the stretcher detachment should never take place during the annual inspection of the regiment. Volunteers should not be allowed to wear the "S.B." badge unless they have reported themselves to, and been accepted by, the regimental medical officer.

MEDICAL SOCIETY OF LONDON.

THE meeting on Monday evening last (January 27th) was devoted to hepatic diagnosis and hepatic surgery. The difficulties met with in the diagnosis of hepatic disease were excellently indicated by Dr. Lauder Brunton, who related ten cases in which the symptoms were either very doubtful or were positively misleading.

Mr. Knowsley Thornton followed with a list of cases in which he had operated on cases of liver disease, thus completing his record of cases up to date. His cases confirmed the thesis formulated by the previous speaker, viz., that the most skilled not unfrequently go wrong in matters of diagnosing liver tumours. He pointed out that for the surgeon to obtain the best possible results, it was essential that he should be able to think the case over beforehand, and plan his line of action in view of the possible and probable contingencies, a thing which, he remarked, was impossible, unless he had a reasonably correct diagnosis to work upon.

Mr. Frederick Treves commented on the fact that while in the event of a diagnosis of cancer it but rarely happened that the diagnosis had to be revised it was very common for the diagnosis of impacted gallstone and the like to have subsequently to be changed into one of cancer of the liver. He mentioned, however, a case in which, even after inspecting the liver, the diagnosis of cancer which was then made had ultimately to be abandoned. This led him to remark that even on examining the liver *de visu* it was not always easy or even possible to arrive at an immediate and correct diagnosis. He discouraged too-persistent attempts to dislodge impacted gallstones after operation, pointing out that they would often come away spontaneously if left to themselves. He believed that many patients lost their lives by reason of these attempts. He concluded with a word of praise in favour of the use of iodoform gauze for packing the wound.

Dr. Sansom pointed out that under ordinary circumstances the area of cardiac dulness was coterminous with the hepatic dulness and the existence of an interval of resonance authorised the inference of shrinkage of the liver *qua* cirrhosis.

Mr. Marmaduke Sheild followed with notes of three cases of hepatic trouble in which he had operated and Mr. Turner related another.

THE FORTHCOMING INTERNATIONAL PERIODICAL CONGRESS OF GYNÆCOLOGY AND OBSTETRICS.

THE Second Session of this Congress is to be held at Geneva, Switzerland, in the first week of September.

In the Section for Gynæcology the following is the official programme:—(1) Treatment of Pelvic Suppurations—Reporters: Dr. Bouilly, Paris; Dr. Kelly, Baltimore; Dr. Zweifel, Leipzig. (2) Surgical Treatment of Uterine Retro-deviations—Reporters: Dr. Kuetner, Breslau; Dr. Pozzi, Paris; Dr. Polk, New York. (3) What method of closing the Abdomen presents the best guarantee against Abscesses, Eventrations and Hernias?—Reporters: Dr. Granville-Bantock, London; Dr. La Torre, Rome.

In the Section for Obstetrics:—(1) Relative frequency and most common forms of Pelvic Contractions in different races, groups of countries or continents—Reporters: Dr. Fancourt Barnes, London; Dr. Dohrn, Königsberg; Dr. Fochier, Lyons; Dr. Kufferath, Brussels; Dr. Jentzer, Geneva; Dr. Lusk, New York; Dr. Rein, St. Petersburg; Dr. Pawlick, Prague; Dr. Pastalozza, Pavia; Dr. Traub, Leyden. (2) Treatment of Eclampsia Reporters: Dr. Charles, Brussels; Dr. Charpentier, Paris; Dr. Halbertama, Utrecht; Dr. Loehlein, Giessen; Dr. Mangiagalli, Milan Pavia; Dr. Parvin, Philadelphia; Dr. Smyly, Dublin.

As indicated by the number and choice of reporters, the Committee, desirous of provoking upon certain questions, investigations, and debates as general as possible, has endeavoured to present the opinions of the principal schools for discussion, and it is hoped by the Committee members of the profession engaged in this speciality will attend in large numbers and take part in its discussions or read original communications. Switzerland has always extended a cordial welcome to Congresses held in that country, and this may be taken as a guarantee that the reception which will be given will be worthy of its traditional hospitality. The Committee of Organisation will make all preparations that members of the Congress and their families may be assisted in combining their journey to Geneva with other excursions in different parts of Switzerland.

The regulations are briefly these:—The founders and

permanent or life members pay a single initiation fee of 300f. (£12), which absolves them from the payment of any future dues. Members for one session only pay a fee of 30f. (24s.), upon the receipt of which they will receive a card of membership to the Congress, entitling them to all privileges during that session, as well as a copy of the Proceedings of the Transactions of the Congress.

Those desirous of taking part in the discussions are requested to inform the Secretary before the fifth day of July, 1896, stating definitely the questions they desire to discuss.

All oral or written communications must be in English, French, or German.

The Congress will be held in the University Halls, placed at its disposal by the Department of Public Instruction. Sessions will continue from 9 to 11.30 a.m., and from 3 to 6 p.m. Morning sessions will be devoted to original communications; those of the afternoon to the official programme. If necessary, the Committee will decide upon the forming of sections.

The General Secretaries are: Dr. Betrix, for Gynaecology; Dr. Cordes, for Obstetrics. Treasurer of the Committee: Dr. Bourcart.

Secretary General for Great Britain (through whom all correspondence and business will be directed): Dr. Leith Napier, 67 Grosvenor Street, London, W.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

LUNATIC ASYLUMS. THE RELIGIOUS QUESTION.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I have read with interest the two letters addressed to your journal by Dr. Clement H. Sers, containing some observations upon the relationship of religion to insanity, suggested by my lectures. The ground covered by the letters appears to suggest the following two questions:—

(1) Religious functions in connection with sane life; (2) religious excitement and enthusiasm as a cause or symptom of insanity.

In regard to the former, I believe that, from a general point of view, if religion under determined conditions is found useful or essential for the sane, it is likely to be so under conditions otherwise determined and arranged for the insane. Many insane patients, of course, are totally incapable of attending any religious function. Some must be prohibited; others may be encouraged. I may state my opinion, as an asylum physician, that a generic case of religious excitement or enthusiasm may most advisedly be restrained from religious functions until at least the acute symptoms have subsided. I should imagine that the case referred to by Dr. Sers, in which a chaplain is reported to have made some reference in his sermon which caused a patient to commence a violent harangue, probably illustrates an exception to this rule. On the other hand, I presume there can be little doubt that no religious officer will be likely to succeed in accomplishing much for patients without accurate knowledge of insanity and the mental experiences of those whom he seeks to influence. The fact that mental aberration forms a special study and phase of life of course increases his difficulties and limits his possibilities. Otherwise where there is apparent failure, and Dr. Sers seems to suggest very strongly that failure there is, both inside asylums and without, such failures may very possibly be attributed to the deficiencies of the doctrines and discipline of the religion itself and the organisations peculiar to it, and the functionaries associated with it in our day. I cannot, however, agree with Dr. Sers that it should be left to a medical officer to determine and state what he believes to be the true and philosophical faith capable of application to these and other cases. Nor in a medical journal will I seek to add more to what I have stated upon this point than a saying I have heard somewhere, that the Christian religion rightly understood is the truest piece of philosophy which is! If so, I doubt not we shall be told that it is the duty of all medical officers who profess Christianity to assist in the practical application of its precepts where such can be judiciously and safely applied, taking religi-

ous things perforce as they find them, and utilising their own special knowledge to the best possible advantage according to the conditions they find.

In stating that "a true and philosophical religion raises the mind above a mere incidental emotionalism," I used the word "religion" in its literal sense, as derived from *re* and *lego*, to gather and consider, as opposed to *negligens*. I have in no way extended its connotation so as to include fanaticism. When witnessing the outbursts of fanaticism in Morocco and in the East I regarded the demonstrations as examples of "incidental emotionalism," but I have expressed no opinion upon the question of the sanity of such emotional outbursts. So far as I am personally concerned I disclaim any plea on behalf of religious superstition. My words were "with no religion, and no moral obligation, the organism is apt to become a prey to the lust of the flesh." Religion and moral obligation I take to be almost convertible terms, and to me both are equally compatible with intuitionism, utilitarianism, or any other "ism" derived from the study of the laws of life and mind. Moral laws are general principles of action, which an intelligent being must apply for himself in the guidance of his conduct, and the translation of such general principles (expressed either in general abstract form or in the form of a command) into particular actions. Conformity with such precepts of morality I take to be the safeguard against the "lusts of the flesh."

In regard to the second point, a study of the phenomena of insanity has taught me one thing—that great care must be exercised not to form rash or prejudicial conclusions. I apprehend that religious enthusiasm in itself cannot justly be called an evil. Rather I suppose does it embody the most healthy and preservative development of our social forces. Like many other tendencies of the mind it is subject to exaggeration, misapplication, and a predominance of the emotional over the intellectual. I cannot at all, with Dr. Sers, think it open to question that "the cases of religious enthusiasm which culminate in insanity are greater than those which arise from intemperance in alcoholic stimulants." As a matter of fact, the typical cases of religious insanity directly developable from sectarian or even undenominational religious enthusiasm, from religious meditations, exercises, devotions, or superstitions, are by no means so common as they are supposed to be by the uninitiated observer. The true point lies in this, that very many mental cases bear a strongly marked religious, or at least, moral aspect. The psychology of the subject will show, for example, that acute depression, a predominant phase of abnormal emotional life, leads almost necessarily to a religious interpretation. And this is even more the case with many actual sense-perversions. Such, I mean, as have ever been associated with ideas of the supernatural. These are not necessarily caused by religious over-excitement or enthusiasm. They may assume the appearance of it because, being the deepest and most real feelings, desires, and convictions of the perverted organic life or of the moral reaction which accompanies it, they cannot well be expressed or described except in strong serious moral terms. Over and over again does this appear, and often among those least likely to be suspected of any religious predisposition. That these feelings should be clothed according to the prevailing ideas and creed of the patient is an essential reproduction of the mind. But after all this only relates to the form of their appearance, and there are many things which lie deeper.

However, I cannot ask space to pursue this subject further. I can only add, and I have no doubt Dr. Sers will agree with me, that it is our object as physicians to fight against all those influences which tend to produce sense-perversions and emotional intemperance, and to subscribe as best we may to that form of religious belief so far as we can find it practically embodied and effective, which believes in "the larger hope" though it condemns unreservedly the demonstrable superstition and sentimentality which impede its progress and its power. With many thanks to Dr. Sers for his complimentary treatment of my remarks upon a subject which is not only fraught with extreme difficulty, but also requires more skilful handling than I am able to give it.

I am, Sir, yours, &c.,

Bethlem Royal Hospital, S.E. THO. B. HYSLOP.
January 25th, 1896.

THE TITLE OF DOCTOR.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR.—It appears from the case of John Ferdinand, M.D., U.S.A., to which you directed attention in your last impression, that the possessor of an "M.D." diploma not registered in England, no matter what qualifying letters he may append, cannot legally in this country assume the title of "Doctor." Now it is to me not a little remarkable, that in the medical profession, if a man possess any qualification at all he may assume the title of "Doctor" without any doctor's diploma from a university. In the city of Glasgow there are many instances where possessors of the single qualification of "the Faculty" which is merely a qualification to practise surgery, call themselves Dr. —, Surgeon. Now I hold that these men have as little right morally or legally to the title of "Doctor" as the American quack. Again, if a man possesses a degree of "Ph.D.," no matter from what college or diploma shop he may procure it, in Scotland, at least, he is permitted without question, to assume the title of "Doctor." If this be contrary to the law, I invite the attention of Dr. Bateman and the Medical Defence Union to extend their vigilance to Glasgow, and respectfully suggest that before prosecuting and prosecuting vulgar quacks outside the profession we should exhibit clean hands in the matter of honesty within.

I am, Sir, yours, &c.,
D. CAMPBELL BLACK.

Glasgow, Jan. 23rd, 1896.

ELECTION OF DIRECT REPRESENTATIVE FOR IRELAND.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR.—As the election of Direct Representative for Ireland to the Medical Council takes place shortly, and as no definite programme has been placed before the electors, may I, as one deeply interested in the subject of Direct Representation, suggest that the candidates should give answers in this journal to the following questions, so that their views may be fully understood?

QUESTIONS.

Will you actively oppose:

Firstly, any proposal which has for its object the formation of any inferior order of medical, surgical, or midwifery practitioners, and so oppose the proposed repeal of the Medical Act 1886?

Will you actively support:

Secondly, the proposed increase in the present number of Direct Representatives on the Medical Council?

Thirdly, any measure which will make the entrance examination much more stringent than it is now, so that undesirable persons may be "weeded out" at the beginning of the medical curriculum and not at its termination, and so that the present large supply of unqualified practitioners by the medical schools and examining bodies may be greatly lessened?

Fourthly, any proposal which will bring back the system of apprenticeship, so that practitioners may be supplied with assistants?

[By an "apprentice" is meant a person who has passed the entrance examination, put in three years of his medical curriculum, passed the first and second medical examinations, who is not more than twenty-four years old, who must not act as an apprentice for more than two years, and where not more than one such is employed by a practitioner].

Fifthly, the formation of one medical Examining Board in each of the three divisions of the United Kingdom, to conduct the final examination only, all the previous examinations to be conducted as at present arranged?

Sixthly, the proposal that no person shall be permitted to begin his or her medical curriculum until such person has completed the age of eighteen years?

Seventhly, the opening of Poor-law infirmaries for the clinical instruction of medical students, and the recognition of such places of instruction by the medical examining bodies?

Eighthly, the compulsory registration of all stillborn infants?

Ninthly, the amending of the Births and Deaths Registration Act, and the providing for the payment out of the public funds of practitioners for medical certificates of the cause of death?

Answers to these questions would concentrate discussion, provide a definite programme, and allow of a complete understanding of the views held by the candidates upon some of the most anxious questions of to-day.

I am, Sir, yours, &c.,

Liverpool. ROBERT R. RENTOUL.

Flobettes.

A BASIN ENEMA CLIP.

THIS ingenious little appliance is likely to become widely used. It has been designed to hold the tail of an enema syringe firmly at the bottom of the basin, beneath the liquid, making the entrance of air impossible. We have found that it fulfills the purpose for which it has been introduced admirably. Nurses will find the clip especially useful. We may also point out another feature in its construction. It can be made to act as a rest for the bone rectal (or vaginal) tube after the enema had been administered, by which is avoided the wetting of bed linen or soiling of the floor or table. The two illustrations which we append will show more definitely how the clip acts. The makers are Messrs Reynolds and Branson, Leeds.

Laboratory Notes.

TERROL.

TERROL is a therapeutic body produced from crude petroleum. It is a bland, perfectly tasteless and odourless hydrocarbon, viscid at 16° C., but slight warming suffices to convert it into a clear yellow oil having a sp. gr. of 0.864 at 100° F. The chief claim put forward in favour of Terrol is that it can be taken as a substitute for cod liver oil, and numerous testimonials have been given by English and American medical men attesting its efficacy in pulmonary complaints, phthisis, and other wasting diseases; but *celoris paribus*, its great advantage seems to be the indubitable fact of its being perfectly tasteless and odourless, therefore it would be exceedingly useful in those numerous cases in which cod liver oil gives rise to nausea and eructations, as we have found that Terrol can be tolerated by the most sensitive stomach. Another point in its favour—and this would appeal to the masses—is its cheapness.

Sir Willoughby Wade.

In response to an invitation circulated by Dr. E. Rickards and Mr. T. F. Chavasse (Senior Physician and Surgeon respectively to the General Hospital), a large number of professional and lay friends of Sir Willoughby Wade met at the Birmingham Medical Institute last week for the purpose of taking steps to publicly congratulate the new knight on the honour recently conferred upon him. Sir Henry Wiggin presided, and was supported by a representative assemblage of leading practitioners and other prominent citizens. The Chairman spoke of the general gratification felt throughout the city at the latest recognition of Sir Willoughby's eminent services, not only to the medical profession, but to society at large, and said that there was a general feeling that the occasion of his elevation to a knighthood offered a fitting opportunity to his many friends to testify their appreciation of his honourable character. These observations were endorsed by a number of other gentlemen present, including Dr. Agar, Mr. Oliver Pemberton, Dr. Lloyd Owen, Dr. A. Oates, &c.

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ORIGINAL ARTICLES or **LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

LOCAL REPORTS AND NEWS—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

REPRINTS—Authors of papers requiring reprints in pamphlet form after they have appeared in these columns can have them at half the usual cost, on application to the printers before type is broken up.

THE LATE DR. KISBY—A DESERVING APPEAL.

SIR,—The following is a revised list of subscriptions received to date. The appeal was inserted in THE MEDICAL PRESS AND CIRCULAR, Jan. 16th.

Subscriptions will be gladly received by any of the committee or by myself.

I am, Sir, yours, &c.,
P. M'KENNA, M.B., Hon. Sec.

A COLONIAL SUBSCRIBER.—We are sorry you ventured to make a bet with a brother practitioner, as your authorship is wrong, and there is a mistake in the quotation. The lines are by J. R. Lowell, and the correct quotation is:—

"The world advances, and in time outgrows
The laws that in our fathers' time were best;
And doubtless afterward, some purer scheme
Will be shaped out by better men than we,
Made wiser by the steady growth of time."

DR. WATSON.—1. Stewart's new physiology is the latest book on the subject, and can be highly commended. 2. The book you mention is not to be compared with Gray. 3. It is, we understand, of American origin, but we can express no opinion of its merits, not having seen it.

THE INCREASE OF THE MEDICAL PROFESSION.

In a chatty article entitled "How People Live," in the January number of *The Leisure Hour* magazine, the writer has compiled his statistics from the official census returns of the last twenty years, and states that whereas lawyers have failed to keep pace with the normal growth of population medical men and dentists have increased beyond the normal proportion, lady doctors have increased fourfold during the last ten years, and lady dentists doubled their numbers during the same period.

Meetings of the Societies.

WEDNESDAY, JAN. 29TH.

SOCIETY OF ARTS.—8 p.m. Mr. W. J. Dibdin: Standards of Light.

THURSDAY, JAN. 30TH.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (Rooms of the Medical Society of London).—8 p.m. Card Specimens:—Mr. Simeon Snell: Alveolar Carcinoma of Upper Eyelid.—Mr. J. R. Lunn: Nystagmus following an Injury to the Forehead.—Mr. C. D. Marshall: (1) Result of Removal of Chip of Metal from the Vitreous by the Electromagnet; (2) Cholesterol in the Anterior Chamber.—Messrs. Holthouse and Batten: Peculiar Condition of Optic Discs in a case of Choroidoretinitis. 8.30 p.m.—Papers:—Dr. Geo. J. Bull: The Camera in relation to Refractive Error.—Messrs. Eales and Sinclair: Moral Cyst of Iris.—Dr. F. M. Ogilvie: Optic Nerve Atrophy in Three Brothers.—Mr. Holmes Spicer: Recurrent Paralysis of Third Nerve with Migraine.

MONDAY, FEB. 3RD.

THE MEDICAL SOCIETY OF LONDON.—8.30 p.m. The first of the Lettsomian Lectures by Mr. W. Watson Cheyne, F.R.C.S., F.R.S.: The Objects and Limits of Operations for Cancer.

Vacancies.

Chichester Infirmary.—House Surgeon. Salary £80 per annum, with board, lodging, and washing. Applications to the Secretary on or before February 17th next.

Metropolitan Asylums Board.—Dispenser at the Eastern Fever Hospital, Homerton. Salary 85s per week, with dinner daily. Printed forms, upon which only applications will be received, may be obtained at the offices of the Board, Norfolk House, Norfolk Street, Strand, W.C.

Oldham Infirmary.—Junior House Surgeon. Salary £50 per annum, with board and residence. Applications before the 4th day of February to the Secretary, E. Lionel Blake.

Sligo Infirmary.—Trained Nurse wanted.—Salary £25 per annum, with rations, &c. Election 11th Feb. (See advert.)

St. Giles's, Camberwell.—First and Second Assistant Medical Officers for Infirmary at Camberwell and their Workhouse at Peckham. Salary of the First Assistant £120 per annum, rising to £160, with apartments, board, and washing; that for the Second Assistant £50, with apartments, board, and washing. Forms of application of Charles S. Stevens, Clerk to the Guardians, Peckham, S.E.

St. Thomas's Hospital.—Assistant Ophthalmic Surgeon. Applications with testimonials should be forwarded to Mr. E. M. Hardy, Treasurer's Clerk, before Saturday, 1st Feb., from whom all necessary information may be obtained.

University of Glasgow.—Four Examinerships in Anatomy, Midwifery, Medical Jurisprudence, and Botany respectively. The salary attached to the Examinership in Anatomy is £40 per annum, and to the others £30 per annum. Immediate application to the Secretary of the Glasgow University Court.

The Middlesex Hospital Medical School.—Lectureships on Anatomy and Physiology. Applications to the Dean of the Medical School, from whom all further information may be obtained.

Appointments.

BRIDGER, S., L.R.C.P.Lond., M.R.C.S., Assistant House Surgeon to the Devonshire Hospital, Buxton.

DEANS, W., M.B., C.M., Aberdeen, Medical Officer for the Ewood Bridge Sanitary District of the East-riding Union.

FOULERTON, A. G. B., F.R.C.S. Eng., D.P.H. Camb., Demonstrator of Biological Chemistry to the Institute of Preventive Medicine.

GOULD, J. E., M.D. Lond., D.P.H. Camb., Medical Officer of Health and Physician to the Fever Hospital for Bolton.

GROVES, H. C., L.R.C.P., L.R.C.S. Ire., Deputy Medical Officer of Health for the Borough of Monmouth.

HORNER, W. E. L., M.B. Lond., House Physician to the Derbyshire Royal Infirmary.

KELLY, T. G., B.A., M.D. Dubl., Examiner to the St. John Ambulance Association.

MILES, A., M.D., F.R.C.S. Ed., Surgeon to the Leith Hospital.

NORGATE, E. H., L.R.C.P. Lond., M.B.C.S., Resident Medical Officer to the Fishponds Workhouse of the Bristol Union.

OLVER, R. S., M.R.C.S., House Surgeon to the Derbyshire Royal Infirmary.

PRINGLE, G. L. E., M.B., C.M. Edin., Medical Officer for the Third Sanitary District of the Bidewater Union.

SAVILL, T. D., M.D. Lond., M.R.C.S., D.P.H. Camb., Physician to the Hospital for Nervous Diseases, Welbeck Street London.

THOMAS, J. T., L.R.C.P. Lond., M.B.C.S., Medical Officer of Health to the Camborne District Council.

WILKINSON, J., M.B., C.M. Edin., Medical Officer of Health for the Boston Rural Sanitary District.

Births.

ELLIOT.—Jan. 21st, at Madras, the wife of Surgeon-Captain E. H. Elliot, Indian Medical Service, of a son.

SEDEWICK.—Jan. 26th, at St. Medards, Cambridge, the wife of Adam Sedgwick, F.R.S., of a son.

Marriages.

LODGE—FOLKER.—Jan. 23rd, at St. Mark's Church, Shelton, Stoke-on-Trent, Alexander John, fourth surviving son of the Rev. Samuel Lodge, canon of Lincoln, to Edith Emily, eldest daughter of W. H. Folker, Esq., F.R.C.S., of Bedford House, Hanley, Staffs.

Deaths.

ALSETTE.—Jan. 18th, at Osmaston Road, Derby, John Alsette, M.R.C.S., Surgeon-Major (retired), aged 59.

BRIDWOOD.—Jan. 20th, at the residence of his father, The Green, Stafford, John Francis Bridgwood, M.R.C.S. Eng., L.R.C.P., aged 52.

BYRNE.—Dec. 18th, 1895, at Ross, Tasmania, Hugh J. Byrne, J.P., L.R.C.S.I., Resident Surgeon, Ross, Tasmania, youngest son of the late Hugh Byrne, F.R.I.A., of Dublin.

GRAVES.—Jan. 24th, at his residence, 27 Fitzwilliam Street, Dublin, William Robert, eldest son of the late Anthony K. Graves, of Rosbercon Castle, aged 44.

MCWHINNIE.—Jan. 24th, at The Chimes, Streatham Common, Harnist, wife of John McWhinnie, M.D., K.N.

WEEKES.—Jan. 27th, at Mansion House, Brompton, Chatham, Hy. Weekes, M.B.C.S., L.R.C.P., J.P., aged 51.

WHITE.—Jan. 19th, whilst on a visit to Dinard, Brittany, Francis S. White, M.B.C.S., L.S.A., aged 39.

WILSON.—Jan. 22nd, at Broughville, Cheltenham, Edward Wilson, L.R.C.P. Lond., M.R.C.S. Eng., aged 58.

NOTICE—Announcements of Births, Marriages, and Deaths in the families of Subscribers to this Journal are inserted free, and must reach the publishers not later than the Monday preceding publication.

Original Communications.

POST-GRADUATE CLINICAL DEMONSTRATIONS.

By JONATHAN HUTCHINSON, LL.D., F.R.S.,
F.R.C.S.,

Consulting Surgeon to the London Hospital, and late President of the
Royal College of Surgeons, England.

[Specially Reported for the MEDICAL PRESS
AND CIRCULAR.]

AMONG the cases shown and demonstrated upon recently was one of

DERMATITIS AND DISEASE OF NAILS

in connection with occupation. The patient was a man of 50, whose occupation was that of a groom, and the affection of the skin of the hands and of the nails had developed in consequence of his hands having been continually soaked in water while washing carriages. The hands were tremulous, cold, and the circulation in them feeble. He had been liable to chilblains in childhood. This case was similar to one which Mr. Hutchinson had just seen. An old gentleman came to him who had dusky cold hands, and an unhealed sore on the back of the leg. This sore had remained unhealed for a very long time; nothing seemed to be of any use in getting it to heal. All sorts of remedies had been tried, but in vain. The medical men who had seen it had told the patient that it was due to unhealthy blood, but Mr. Hutchinson believed that the unhealthy condition of the wound was the result of feebleness of circulation. A very interesting point in the history of the case was that neither the patient nor his father had ever been able to tolerate a cold bath. A cold bath always made their fingers livid, and afterwards turn quite white. And yet the patient was in other respects a strong robust man. Another case, which Mr. Hutchinson had lately seen, of this affection of the hands was that of an old gentleman, who took to gardening in cold weather. In the treatment of these cases good nutritious food was requisite, and it was highly essential that an indoor, instead of an outdoor, occupation should be followed. Again, minute doses of opium seemed to act wonderfully well.

EARLY STAGE OF RAYNAUD'S DISEASE.

The patient was a woman, æt. about 36, in whom the early symptoms of Raynaud's phenomena were present upon the hands. Her fingers first began to go "white" about two years ago. She noticed that one finger at a time became cold and stiff. To bend her fingers quite straight was now impossible. There was no change in the nutrition of the skin as yet, and the nails were quite healthy. The coldness of the fingers was always worse in the mornings, but if anything "upset" her—that is, if she suffered any emotional disturbance, the symptoms at once became worse. There was nothing noticeable about the ears or toes. She had not suffered much from chilblains in early life. About three years ago there was a history of syphilitic infection having occurred.

PECULIAR SORE UPON THE FOREARM.

This patient, a healthy old man, æt. 80, came from the Union Infirmary of St. Pancras. The sore upon his forearm was a very peculiar one. About December 1894, something like a boil appeared on the outer and front aspects of the right forearm, a little below the elbow. In July 1895, the disease had considerably increased in size and a discharging wound had formed. The measurements now were four inches and one-eighth by four inches. The wound had a distinctly spreading edge, the latter being sinuous and remarkably bossy, but not very hard, the skin had been destroyed in the centre of the sore, the ulceration having been quite superficial. The point of interest was—what was the nature of the disease. Was it allied to a senile form of lupus, or was it malignant. There were no enlarged glands in the axilla. The exact diagnosis was very doubtful.

BAZIN'S MALADY.

The patient was a girl, æt. 17, who partly came to show herself with a large patch of Bazin's disease over the middle of the back of the left leg. Her case, however, was chiefly interesting because of the sequelæ of infantile paralysis which were present. There was a complete absence of the left deltoid muscle, consequently, she had no power to raise the affected limb. When she wanted to raise the latter, she grasped the limb with the other arm, and so lifted it up. Infantile paralysis of the deltoid was very common, indeed, it was the deltoid which of all the muscles was most liable to be paralysed alone. And the present case was a good example of the kind. Mr. Hutchinson stated that he recently saw a gentleman in whom there was infantile paralysis of both deltoids, and it was interesting to watch how by the use of his pectoral and other muscles the patient was able so to raise his arms as to reach down a book from a top shelf in a library. The head of the humerus in the patient under discussion could be freely moved in all directions, and examination showed that the biceps was scarcely at all to be felt, while there was exceedingly little power in the triceps, and brachialis anticus of the affected arm. But there was no loss of nutrition so far as the hands were concerned. This was the rule, motor paralysis was generally not associated with nutritional changes.

The next case was one of

LICHEN PLANUS.

The patient, a woman of fifty-six, had for six weeks noticed some flat patches, polished on the top, on the front of her wrists. The smooth polished top was characteristic of the disease from which she was suffering, namely, lichen planus. The disease was a very peculiar one. Sometimes it appeared suddenly, sometimes more slowly, and lasting a few weeks or months, then spreading over the body. It was especially prone to develop at the wrists and ankles, and at the waist, where the corsets pressed. It differed from psoriasis in the mode of its onset; moreover, whether treated or not lichen planus would get absolutely well; psoriasis, on the other hand, never disappeared spontaneously. Again, a patient who had had one attack of lichen planus might become perfectly well, and remain so for several years, and then have a relapse. It had been said that there were cases which did not recover. But

that was an experience which had not come under Mr. Hutchinson's notice. The tendency in cases of lichen planus was to spontaneous cure. Still, the disease proved very intractable in some instances. Mr. Hutchinson stated that he published the notes of a case of lichen planus which he had cured with antimony. The disease was very extensive, the patient having been covered from head to foot with the characteristic patches. Treatment with arsenic only made matters worse. Quite by accident antimony was given, and then a rapid cure resulted. The cure was so quickly brought about that Mr. Hutchinson did not see the patient again, although some years had elapsed, until three months ago, and then he returned with a relapse of his former malady. There was never any tendency to desquamation present in cases of lichen planus. It was somewhat curious that the patches of the disease had their long axes transverse to the limbs upon which they developed.

LUPUS ERYTHEMATOSUS.

The patient was a man, *æt.* 36, whose face was covered with lupus erythematosus; the disease first appeared on his left ear, and then gradually involved the whole of his face. One of his sisters had died of phthisis, but no other member of his family had seemed ever to have suffered from tuberculosis. Some years ago he was out of health, had a cough, and lost flesh, and he was ordered a sea voyage. Since then he had enjoyed good health, except for his face. Mr. Hutchinson stated that the association of great tendency to chilblains in early life was almost constant in cases of lupus erythematosus. This feature, together with an inherited tendency to tuberculosis, formed the two elements which chiefly contributed to the development of this disease. It was commonly said that lupus erythematosus was often seen on the scalp, while lupus vulgaris was never seen in that situation. But in Mr. Hutchinson's opinion the distinction was an arbitrary one; his belief was that lupus vulgaris did affect the scalp. There were several marked points of distinction between these two varieties of lupus. In lupus vulgaris, after the lapse of a certain period, no increase in the number of patches occurred, but the disease remained; the disease, if unrelieved by treatment, was a life-long malady, although it only continued to spread after a certain time. Lupus erythematosus, on the other hand, for long maintained its infective qualities, and spread largely. Nevertheless, in time, its infectiveness ceased; the disease appeared to wear itself out, it declined spontaneously, and then became cured. Moreover, it was nearly always possible to obtain a tuberculous history in the patient in these cases. Despite, however, this connection, so far, no evidence of tubercle bacilli had been obtained from a bacteriological examination of the patches of lupus erythematosus.

SYCOSIS.

This patient was a young man upon whose left cheek there was a patch of sycosis, which had first been noticed about four months ago. Mr. Hutchinson observed that this disease was characterised by pustular inflammation of the hair follicles, together with inflammatory exudation about the hairs. The adjacent tissues were "baggy," and a glutinous material was exuded, as in kerion. Some of the most typical cases of sycosis were not parasitic, but, on the contrary, were more allied to lupus. The disease spread in patients suffering from it by continuity and contiguity of tissue; it was, therefore, infective to the patient's own skin. The treatment of these cases was based upon the recognition that the disease depended upon some infective material. The first thing, therefore, to be done was to pull the hairs out of their follicles, then thoroughly wash the part with soap and hot water, so as to make the skin quite soft, and then rub in well some mercurial ointment.

ALOPECIA AREATA.

Two small children were next shown, suffering from alopecia areata, in whom from the beginning of the cases no evidence of ringworm had been obtainable. The treatment which had been followed was that of rubbing the bare patches with chrysophanic acid ointment.

A SERIES OF CASES

OF

INTESTINAL RESECTION.

BY HERBERT W. ALLINGHAM, F.R.C.S.,

Surgeon to the Great Northern Hospital, Assistant Surgeon to St. George's Hospital.

(Concluded from page 103.)

CASE VI. *Resection of Stricture of Transverse Colon.*

—Jane S., *æt.* 56, was admitted on October, 1894, into the Great Northern Hospital. She was extremely ill, and from what we could gather she had had for a long time great trouble in getting the bowels to act. For the last month they had acted only on three occasions, and then with very small motions.

On examination the abdomen was greatly distended, there was dullness all along the ascending colon, but the descending colon and sigmoid flexure appeared to be empty. An incision, therefore, was made at once, about the umbilicus. On the abdomen being opened it was seen that the intestines were enormously distended, and that the transverse colon presented. This was empty, and on passing it through one's fingers, and examining towards the ascending colon, I found towards its hepatic end a hard, tight, annular malignant stricture. The abdominal wound was then enlarged upwards so as to give a good view of the stricture, and as the disease was found to be so limited in its extent and the stricture small, I determined to resect. This was done with difficulty on account of the distension, the ends of the bowel being brought together over Mayo Robson's bobbin. In putting in the additional Lembert's sutures it was discovered that the peritoneum about the distended portion of the intestine was extremely rotten, so that the stitches had a tendency to tear through.

The patient died thirty hours afterwards, and never appeared to recover from the shock of the operation upon one so seriously ill.

The post-mortem showed that there was no leaking about the bobbin, but the intestines were so enormously distended as to seem to have been unable to empty themselves.

CASE VII. *Resection of Stricture of Sigmoid Flexure.*

—Miss R., *æt.* 56, had always had good health, but for the last eight months had great difficulty in getting the bowels to act. Of late the bowels never acted without purgatives, and when these were administered they occasioned griping pains in the abdomen, and the patient described that there was a feeling of stoppage about the sigmoid region. When I saw her the bowels had not acted for about ten days. About the large intestine could be felt hard scybalous masses, and there was a hardish tender mass to be made out in the left iliac fossa. On examination per rectum nothing abnormal was to be noted. Injections and medicines failing to relieve the obstruction, on October 21st, 1894, on opening the abdomen by an incision five inches long and introducing the hand into the interior of the large intestine, commencing at the lower part of the sigmoid flexure, and tracing it through my hand I discovered about the middle of it a hard annular, malignant stricture. The intestines above the stricture were filled with old, scybalous masses.

As this seemed to be a very favourable case for excision of the stricture, with india-rubber drainage tubes above and below, I resected the stricture and a

V-shaped piece of the mesentery, and brought the ends of the gut together over a large-sized Mayo Robson's bobbin.

After the operation the patient complained of a good deal of pain and was slightly sick. The abdomen was in no way distended. On the 22nd the patient was reported to have had a fair night, the pulse was 100, the temperature 99°; the aspect was good; there was no distension or tenderness; flatus had been passed.

On the 23rd the patient was said to have had gripping pain in the stomach, temperature was 99°6', the abdomen was not distended, and she passed a quantity of wind.

On the 24th she had had more pain in the abdomen over the seat of the operation, and the abdomen was rather tender about that part. Temperature was 101°, the aspect was not so good.

On the 25th the patient had had a bad night with great pain about the seat of the wound, the temperature had fallen, there was no general distension in the abdomen, and the pain was confined to the left iliac fossa. I therefore took out two skin stitches and passed a probe down towards the seat of the union of the gut. This allowed a little gas and some serous fluid to exude. I did this in the hope that had any of the suturing given way (which evidently was the case) flatus or fæces might pass through the abdominal wound rather than into the general peritoneal cavity.

On the 26th she had had a better night and seemed to be relieved by what had been done. She said she felt as if her bowels wished to act, and on examining the rectum, I found the bobbin there and some hardened masses of fæces. Some flatus had passed by the abdominal wound. About the middle of the day she complained of sudden pain in the abdomen, became collapsed, and soon died. I have no doubt that this was due to some other part of the suturing in the gut having given way into the peritoneal cavity.

CASE VIII. Resection of Stricture of the Sigmoid Flexure—Harriet T., æt. 34, was admitted into the Great Northern Hospital under the care of my colleague, Dr. C. E. Beevor. She gave the following history. For about eight months she had been troubled with her bowels, at first by diarrhoea, but for the last two months with constipation, together with frequent attacks of colicky pains and occasional vomiting. Various drugs were given in the attempt to relieve her, but with little or no result; on some hardness being discovered in the left inguinal region, Dr. Beevor asked me to see the patient with him. I observed the abdomen to be somewhat distended, any manipulation of the abdomen caused peristaltic action of the intestines, and in the left inguinal region could be felt a hard, irregular mass.

As the patient was getting worse, on January 30th, 1895, I opened the abdomen by a curved incision in the left inguinal region, and on exposing the sigmoid flexure, noted a hard, annular, malignant stricture involving the gut. This was resected and the ends of the intestine were approximated by Murphy's button. The next day the patient appeared to be fairly comfortable, some flatus had been passed by the rectum, the abdomen was in no degree tender, and the temperature was good.

On February 1st the patient began to get somewhat distended, so a small turpentine enema was given, but with no result. There was no tenderness about the abdomen and the aspect was good. On February 2nd, as the distension was increasing, another turpentine enema was given and repeated doses of sulphate of soda administered; there was still no result. On February 3rd, as this state of things continued, the patient died, complaining a few hours before death of great pain in the abdomen.

At the post-mortem it was seen that at one part of the gut the intestine had sloughed and there was some extravasation of fæces into the peritoneal cavity. The

intestine above the button was greatly distended and the hole through the button was absolutely blocked by a hard mass of fæces.

CASE IX. Resection of Stricture of the Small Intestine.—Ellen H., æt. 44, was admitted into the Great Northern Hospital with the following history. For twelve years she had had an umbilical hernia, which became strangulated and remained strangulated for five days before it had been operated upon. Fourteen days after the operation fæces commenced to come through the abdominal incision, and had done so ever since. The bowels also acted occasionally per rectum. Since the operation she had been subject to continued gripping pains in the belly.

On admission, the abdomen was flaccid, and occasional peristaltic action of the intestines could be perceived through the abdominal wall. Situated in the position of the operation wound, about the umbilicus, were two small openings through which came liquid intestinal contents.

The patient was well purged every day for a week prior to the operation, which I performed on April 24th, 1895.

An incision was made five or six inches long just to the right of the middle line, the fæcal fistula being about the centre. A probe was passed through the fistula previous to the incision. Having cut through the abdominal wall, and the peritoneal cavity being opened, I found that the intestines, both large and small, were extensively matted together about the umbilicus. Situated in one part of the small intestine was discovered a very tight stricture. The proximal end of this part of the intestine was considerably dilated, the distal end quite collapsed.

Great difficulty was experienced in separating the adherent coils one from the other, and in doing this in several places rents were made in the intestines. These rents were immediately closed by a continuous suture, uniting the mucous surfaces, the serous surfaces being brought together by Lembert's sutures. When the intestines were separated one from the other attention was then turned to the strictured small intestine. The strictured gut was brought well out of the abdomen, the fibrous stricture, with about an inch of gut on each side, was resected, and the fluid contents of the upper distended portion of the gut, were allowed to run out into a basin. Then the two ends of the gut from which the stricture had been removed were united over a Mayo Robson's bobbin. The old sinus in the abdominal wall was cut away, and the abdominal incision was brought together with silk-worm gut sutures.

It is needless in a successful case to narrate the after treatment. The patient made an uninterrupted recovery, and left the hospital on May 28th perfectly cured.

CASE X. Resection of a Piece of the Small Intestine for Large Fistula.—Emily D., æt. 18, in January, 1895, was in the Chelsea Hospital, where she had the abdomen opened and flushed out, and a drainage tube inserted for tubercular peritonitis. A few days after the operation fæces began to come through the abdominal wound and continued to do so ever since.

There was no tubercular history in the family. The patient was a very thin and hectic-looking girl. There was no evidence of tubercle about the lungs.

On examination of the abdomen it was noticed that midway between the umbilicus and the pubes was an irregular unhealthy-looking wound from which fæces exuded in considerable quantities. At the lower part of the wound also was a large sinus, through which pus flowed. This sinus apparently led down towards the pelvis.

Temperature at night was usually about 102°. The bowels acted two or three times through this fistula, and the patient was evidently losing ground.

On June 5th I explored these sinuses by making two

horizontal incisions outwards, which exposed a large abscess cavity dipping right down into the pelvis, and on the floor of the cavity was a piece of small intestine, in which there was a large perforation. The intestine was freed from adhesions and was noticed to be studded with tubercles. This was then brought well out of the wound, and I resected about two inches of the gut which contained the perforation. The ends of the gut were then brought together over one of my bobbins, and Lambert's sutures were applied outside. The large abscess running down into the pelvis was then thoroughly scraped out, and the gut with the bobbin was put back into the abdomen. The belly wound was left open so as to allow of thorough drainage.

On June 15th the now decalcified part of my bobbin was passed by the rectum. The next day, just below the seat of enterostomy, a small pinhole opening was observed, from which fæces exuded at times.

The patient was putting on flesh rapidly and her appetite was good.

From this small opening fæces have ever since exuded. These irritate the wound and the tissues around, and seem to prevent sound healing. Also, at times, from the large pelvic cavity some pus exudes. Considering the tubercular condition of the intestines it is a wonder that any union took place over the bobbin. I hope that, as the external wound heals and contracts, the small opening into the intestine will eventually close.

It will be seen that I have operated upon ten cases requiring resection, six recovering and four dying.

In four of the cases that recovered, Cases II, III, IX, and X, the intestines had been emptied prior to the operation of resection.

In the four cases that died, Cases IV, V, VI, and VIII, resection of the diseased portion was done when the intestines were loaded with fæces. From this, it will be perceived that distension of the intestines at the time of the resection enormously increases the risk of the operation. The following appears to be the explanation:—When the intestines are distended large quantities of fæces are pressed down towards the seat of union, and no doubt are constantly disturbing it by the peristalsis they set up. Further, the patient is, in a way, poisoned by the fæcal accumulation, and when he is in such a state, it is easy to understand that union between the divided ends of the intestine may be delayed, or take place in a feeble, and even imperfect, manner.

To look at the matter in another light:—

When the large intestine is dealt with obstruction has been present for some time, and the fæces are solid or semi-solid. They therefore may press upon the seat of union, or if a bobbin has been used, may block it as in Case VIII, or tear it away, as in Case VII.

With the small intestine, however, the case is different. For in this part, however long the obstruction may have existed, the contents are always fluid; hence there is less danger of the bobbin or button being blocked, or of pressure causing it to break away from its situation.

We may therefore arrive at the following conclusions:—

Stricture of the *large* intestine must *not* be resected when the intestine about the stricture is *distended* with fæces.

Stricture of the *small* intestine may be resected even when the gut is distended, for the fæces are liquid.

I have, therefore, modified my methods when dealing with strictures of the large intestine.

The gut, quite close to and just above the stricture, should be fixed into the abdominal wound; in fact, a colotomy should be performed, so that the intestines by means of purgatives may be thoroughly cleared of their contents. When this has been effected, and the patient has recovered in general health, a second operation should be performed, which consists of free-

ing the artificial mass from its attachment to the belly wall, and resecting it and the stricture in one piece.

Sometimes it may be possible to bring the strictured piece of gut out through the abdominal wound, and to open the gut on the proximal side of the stricture. In this way the intestines can be thoroughly emptied. About ten days afterwards, the opening in the gut and the stricture can be removed in one piece by applying a strong clamp to the protruding portion of the gut. This is exemplified by Case I. Some months later the artificial anus may be freed from the belly wall and resected, the ends of the gut being united over a bobbin.

Some surgeons at the time when the artificial anus and stricture are removed—that is to say, about ten days after the first operation—advise that the ends of the divided gut should be united *at once* over a bobbin. This procedure appears to me to be unwise, for, as a rule, a patient requires some weeks or even months for thorough recovery, and until then the making of an end-to-end union is not safe.

It is now evident to my mind that with these resections, as with all other cases of intestinal anastomosis, the use of some form of button or bobbin is absolutely imperative. These appliances prevent contraction or dilatation of the gut at the seat of union, and there is less likelihood of leakage in the line of suturing. If no bobbin is employed, and Mounsell's method is used, as in Case IV., the seat of suturing is unsupported, and a leak between the sutures may occur.

Another use of a bobbin is to secure the rest for the parts which is necessary for sound healing, for, as with other portions of the body, union is favoured when the divided pieces of intestine are kept fixed and in a state of rest.

In the *Lancet* for August 31st, 1895, I discussed the various kinds of bobbins and buttons which are used in intestinal surgery, and described a new bobbin of my own, which I used in Case X. and have used in several cases since with marked success.

Lectures

ON

THE DIAGNOSIS OF INSANITY.

By THEO. B. HYSLOP, M.D.,

Lecturer on Mental Diseases to St. Mary's Hospital Medical School,
Assistant Physician to Bethlem Royal Hospital.

LECTURE VI.

THE mental disturbances which follow typhus fever are not unlike those following typhoid. Some cases exhibit moral perversions, others are maniacal, with or without hallucinations or delusions. Those found that the more common sequelæ were dementia, general maniacal delirium (continuous or intermittent, and of varying duration, with or without hallucinations), partial insanity, or monomania usually of the ambitious type. The onset of acute transitory mania may occur during the early stages of convalescence, and this is believed by some to be due to some sudden change in the cerebral circulation. Weber calls this the "delirium of collapse," and states that with the symptoms of prostration the pulse is feeble, rapid, and irregular; further, that this condition is common at the period of crisis and may be due to sudden anæmia of the brain from heart failure. Westphal and Foville, observed intellectual weakness in relation to variolæ and typhus, and such symptoms as change in physiognomy, slow clumsy movements, movements by fits and starts, trembling of the limbs, partial or general ataxy of limbs, stiff gait, disorders of speech, impaired deglutition, and in one case loss of power of sneezing, whilst mentally there was a certain amount of excitement. Westphal has also noted the scanned, nasal,

and monotonous speech, in which the letters and syllables were not displaced, but separated by intervals and uttered jerkily, or with visible efforts, yet, as after typhoid, without co-existing tremblings of the lips and face. Foville, on the other hand, has noted the occurrence not only of marked twitchings of the face, but also a tendency to convulsive projection of saliva or the return of fluids by the nose during the act of deglutition. The pathology of this condition is at present unknown. The frequent substitution of convulsions for rigors in children is said to indicate the early implication of the nervous centres, and, according to Greenfield, the acute transitory mania may be the analogue of these convulsions affecting the psychical, instead of the motor, centres. In the early stage of typhus there is said to be an increase of the watery constituents of the white matter of the brain. There may be no appreciable organic lesions, the symptoms depending chiefly upon cerebral anæmia and debility. The atony, exhaustion, and anæmia of the brain may be furthered by other influences such as moral shock, &c. The hebetude due to wasting of the nervous matter and nerve tubules may occur as a sequel to any of the more severe fevers.

The most frequent form of insanity following eruptive fevers is said to be maniacal delirium with or without hallucinations. In children the exanthematous diseases play an important part in the ætiology of deafness, and secondarily in the causation of idiocy and imbecility by deprivation of the sense of hearing. Baillarger has recorded a case of *délire ambitieux* of fifteen days' duration following scarlatina. Melancholia with refusal of food and insomnia have been noted after small-pox.

Cholera may be followed by transient delirium, paroxysms of mania, or melancholia. In all febrile conditions insanity may occur, owing to toxic conditions of the blood, or to congestion of the internal organs and brain. These altered vascular conditions may be active or passive, general or partial, chronic or acute. Sometimes the mental symptoms may be attributable to direct excitation from peripheral irritation, the existence of pain, organic disease, &c., producing central exhaustion or irritability; or to reflex irritation, or peripheral irritation acting in a reflex manner, either on the vessels or the nervous tissue itself. Other conditions, such as sub-acute inflammation of the cortical substance or membranes of the brain, capillary embolism, or thrombosis (as in the melanæmia following ague), have been cited as probable factors of causation. Some of the mental disorders may be regarded as instances of metastasis, in which the mental symptoms alternate with the symptoms of the bodily disease.

Rheumatic affections are sometimes followed by insanity. The development of the insanity generally coincides with the fall of temperature, cessation of joint affections, and subsidence of the physical symptoms. The form of insanity is usually one of depression. Sometimes mania with chorea supervenes. In some cases there is agitation with sensory disturbance, refusal of food, and a tendency to delirium; the majority, however, suffer from melancholia, with or without hypochondriasis, or there may be some delusions present, which either gradually pass off or assume the character of ideas of persecution. The more severe forms of insanity, such as dementia, paralytic insanity, and general paralysis, have been observed but rarely. Any form of insanity may occur at any age, associated with rheumatic affections. Transitory mania, in a child, does not generally appear so serious as in an adult. The male sex appears to be mostly affected, and the liability to affection is increased by heredity, previous mental strain, or intemperance.

Pneumonia is sometimes followed by insanity; but the tendency to mental disturbance is not proportionate to the severity of the disease. The onset of acute maniacal delirium usually occurs suddenly towards the

period of crisis, or early in convalescence, and first manifests itself early in the morning after waking from sleep. Many of the more chronic forms have no premonitory symptoms, or there may be loss of sleep and want of mental rest. In addition to the ordinary symptoms of exhaustion following an attack of pneumonia there may be local or general hyperæsthesia, loss of electro-tractility of muscles, and of reflex excitability, paralysis of special nerves or of systems of nerves, various forms of spasm and convulsions, ataxy of movement, hemiplegia or paraplegia. Griesinger has also described a transient form of hemiplegia, and Mickle mentions the occurrence of general paralysis.

Many other febrile conditions are followed by various paralyses or insanity. It would involve too much time to enter upon the consideration of the various paralyses which follow febrile affections. General paralysis does sometimes follow typhus, cholera, typhoid, dysentery, diphtheria, pneumonia, articular rheumatism, erysipelas, &c. Much more commonly, however, these affections are followed by localised or diffused paralyses which simulate general paralysis. According to Mickle, the diffuse form may be distinguished from general paralysis by the more frequent and obvious preceding anæsthesia, analgesia, numbness, pricking and arthritic pains, and by the circumstance that it often begins in the *velum palati*, almost always undergoes recovery in the space of a few weeks, and is rarely accompanied by intellectual trouble. He further states that "should the paralysis be diphtheritic (and even in some other cases) it is apt to extend from the *velum palati* to the pharynx, thence to the lower limbs, then sight and hearing become affected, then the upper limbs, and finally the trunk and respiratory muscles, while the premonitory signs mentioned above are often present. The diagnosis of these conditions is often attended with extreme difficulty, and it is often only late in the course of the disease that its true nature can be ascertained.

Influenza is frequently followed by prominent nervous symptoms. The symptoms may be those of intense nervous exhaustion, sensory or motor affections, paralyses of the oculo-motor apparatus, or of the extremities, usually referable to degenerative neuritis. In some cases hysteria, or neurasthenia supervenes, and a few cases have been recorded of severe organic changes in the central nervous system. The mental symptoms may take the form of acute febrile delirium or the mental derangement may continue for some weeks or months. Most of the mental disorders following influenza tend to disappear with improvement in general health. The graver cases, however, are protracted in their course, and eventually resolve themselves into paralytic or chronic delusional affections.

An attack of malaria may be attended with, or followed by, extreme collapse, coma or delirium, epileptiform or tetaniform convulsions, or mental symptoms of varying intensity and kind. In some cases the occurrence of insanity is a chance coincidence, and not dependent upon malaria as a causal agent. Simple uncomplicated attacks of malaria are rarely followed by mental disturbance; but when the nervous system has been weakened by syphilis, alcohol, and various excesses, not only is some neurosis likely to supervene, but it is likely to be of a serious and intractable nature. Simple cases, where no cause beyond the malaria has been ascertained, generally recover.

Writing upon the influence of malaria in the production of insanity (Fuke's "Dictionary of Psychological Medicine") I pointed out that some neuroses appear to be forms of ague, and may be recognised as malarial, partly by their periodic nature, partly by their superposition on a more or less distinct cold stage, partly by their occurrence in a malarious district, and partly by the fact that the patient has already been the subject of ague. Severe or long-continued intermittents produce a very deleterious effect on nervous power, and

lead to almost any degree of mental deterioration. In addition to muscular weakness, a partial paralysis of one or more limbs is not an uncommon occurrence. Dr. Manson, in his medical report on the health of Amoy, quotes a case of gradual impairment of sight following an attack of dengue fever. Amongst the Chinese he also noted many instances of dyspepsia, debility, rheumatism, paralysis of certain groups of muscles, and insanity, as consequences of dengue. One case admitted to Bethlem was suffering from the ataxic form of general paralysis the sequel to dengue. Pinel has recorded a case of recurring suicidal tendencies after an attack of tertian fever, and Baillarger considers that intermittent fevers predispose to insanity in two ways, first by acting like all nervous affections, and secondly by producing anæmia. Sullivan, writing on the endemic diseases of tropical climates, states that in one patient the effect of miasma produces prostration, in another it produces over-excitement, or increased muscular sensibility; one man may be seized with delirium, another falls into a state of stupor; some are seized with local paralytic affections, or general hyperæsthesia, while others do not complain of pain.

Neuralgic affections of one or other branches of the fifth pair, as in that involving the supra-orbital, and constituting one form of the malady known as "brow-ague," is adduced as an example of a neurosis being a distinct form of ague. Several authors have described intermittent paroxysmal mania or maniacal delirium occurring in the place of an attack of ague, or as its principal symptom. Of the form which follows ague, Sydenham, who first described it, states that acute mania tending to pass into chronic, occurs chiefly after protracted *quartans*. Sebastian, however, states that insanity occurs as frequently after attacks of *tertian* or double *quartan* type, and that, in these cases, it is more commonly of an acute delirious character, whilst after *quartan* it takes on a more chronic form, and tends to pass into stupidity or melancholia.

During an attack of intermittent fever there may be delirium in persons predisposed thereto, and this delirium is not always in proportion to the intensity of the fever; or there may be a condition with exhaustion analogous to the typhoid state of other acute disorders. In severe and prolonged cases of malarial disease there is a tendency to intermittent mental affections, or chronic insanity with or without paralysis. The more important mental conditions are met with as sequelæ, in persons who have passed into convalescence after a very acute or prolonged attack of malaria. These symptoms at such period may be transitory and curable, in the form of quiet delirium, melancholia with or without stupor, or simple mania with or without impulsive tendencies, or occasional outbursts of excitement. These conditions are generally considered incurable. The pseudo-general paralytic type has been frequently observed. It sometimes presents most of the features of general paralysis, with mental and physical symptoms, which, although difficult to distinguish from those of general paralysis, are, nevertheless, somewhat different in their course and duration. Mentally, there is frequently weak-mindedness or slight exaltation, with or without marked delusions. In one case admitted to Bethlem there was partial dementia with confusion, and in another, confusion and hallucinations of hearing. The physical symptoms may be those of nervous debility with tremors, alteration of the reflexes, or even definite symptoms of a system-lesion in the spinal cord. In some cases there is a peculiar appearance of the margin of the tongue after attacks of malaria. This is termed the "malarial margin." Its colour is faintly blue, and there is marked transverse indentation or crimping, apparently confined to the submucous tissue, while the superficial integument continues smooth, moist, and transparent.

It may be of advantage here to speak of some of the

pathological features of malarial affections of the nervous system. Suggestions have been made as to the presence of micro-organisms in the blood, and the existence of pigment in the blood and vessels, but their relation to the mental disorder is at present indefinite. The occurrence of a large amount of pigment in the blood has long been known. Breschet and Cruveilhier detected it in the blood vessels in the form of black, sharply cut masses. Halliday found black pigment in the vessels at the base of the brain, and in those of the choroid plexus. As early as 1825, Billard and Baily observed obstruction of the capillaries of the brain by pigment. Bright described and figured the brain of a man who had died from cerebral paralysis, which appeared to have resulted from an attack of fever. The cortical substance was of a dark colour like black lead. In 1874, Hammond had a patient suffering from deafness, pains in the head, and epileptic convulsions, in whom an ophthalmoscopic examination showed the existence of double optic neuritis, with pigmentary deposit. There was a history of malarial fever in the case, and recovery from these symptoms, including the deafness, followed the use of arsenic. Planer found that in cases in which there were cerebral symptoms, the pigment in the blood was found in a state of black, or more commonly of brown-yellow, brown, or (very rarely) red granules, many of which were united together by a clear hyaline substance, which was soluble in acids and alkalis. Meckel observed pigment cells very rarely; Virchow more frequently. Planer never saw in the pigment masses anything like a nucleus. The aggregation of the pigment grains sometimes formed black or brown flakes of the most variable forms; these flakes were sometimes considered to be constituted by a hyaline substance, in which black pigment was imbedded. The relative number of the pigment masses of the blood globules was not determined. In some cases the capillaries seemed almost choked up with them. He did not find that the colourless corpuscles of the blood were more numerous.

The cerebral substance was often found affected by pigment change, and it appeared certain that the pigment was in the vessels. Meckel describes a case in which there were numerous punctiform hæmorrhages in the grey substance, produced by blocking of vessels through pigment, and since then several cases of the same kind have been seen by Planer. In some cases the flakes, already referred to as seen in the blood in the heart and large vessels, were in the cerebral capillaries, and of such size that it seemed impossible they could pass. In fact, Planer conjectures that the extreme abundance of pigment granules in the cerebral vessels must have been owing to their inability to pass through the cerebral capillaries, which (especially in the grey matter) are the finest in the body.

From this account, it is evident that the pathology of the affliction is, as yet, very indefinite, and we have yet to learn whether, in these cases, excessive pigmentation occurs in the nerve-cells of the brain and spinal cord, and if so, in what way the degeneration differs from the pigmentary changes found in ordinary conditions of functional hyperplasia, as in severe attacks of acute mania, epileptic insanity, or in general paralysis.

From the clinical considerations already mentioned it will be noted how the diagnosis is often a matter of extreme difficulty. The periodic or intermittent nature of the mental attacks may suggest a malarial origin. The beneficial effects produced by the administration of arsenic may help to confirm the diagnosis. I usually prescribe quinine, arsenic, and phosphorus for such cases, and often with beneficial results. Sometimes a diagnosis has to be made between the pseudo-general paralysis following malaria, insanity with paralysis, and general paralysis. It may be well to remember that the mental disorders occurring during

an attack of malaria are generally transitory and curable, unless the malaria is of undue severity, when there is apt to be permanent instability or a chronic form of insanity. The prognosis in the pseudo-general paralytic forms is unfavourable. They seldom terminate like true general paralysis, but go on for years, and die of some complication, or succumb to the advance of a degenerative lesion. Sometimes, when alcohol has formed an additional factor in the causation, the case may do well. When syphilis forms a complication recovery is rare. In one case, formerly in Bethlem, with a history of malaria and syphilis, there was partial dementia, with hallucinations of hearing and lateral sclerosis of the cord. The mental symptoms on the one hand, were of an intermittent type, and did not advance in severity, whilst, on the other hand, the lesion in the cord progressed unfavourably, until death ensued.

Later, when I have considered some of the other factors of causation, I shall better be able to present in tabular form the leading features for differential diagnosis.

Selected Formulae.

(Continued from page 107).

The following prescriptions are taken chiefly from Dr. Murrell's forthcoming work on "Pharmacology and Therapeutics," an advance copy of which is before us:—

APOMORPHINE LINCTUS.

Solution of Apomorphine (1 in 50) 2 drachms;
Solution of Hydrochlorate of Morphine, 1½ drachm;
Dilute Hydrochloric Acid, 1 drachm;
Syrup of Lemons, half-an-ounce;
Spirits of Chloroform, 1½ drachm;
Water to 4 ounces.

A teaspoonful frequently when the cough is troublesome.

CODEINE LINCTUS.

Codeine, 4 grains;
Spirits of Chloroform, 1½ drachm;
Syrup of Virginian Prune, 2 drachms;
Water to 4 ounces.

A teaspoonful frequently to allay hacking cough unattended with much secretion.

PICTOTOXIN PILLS.

Picrotoxin, one-sixtieth of a grain;
Sugar of Milk and Glycerine of Tragacanth, enough to make a pill.

One at bed-time, repeated if necessary, to check the night-sweating of phthisis.

MUSK PILLS.

Musk, 2 grains;
Sugar of Milk, enough to make 12 pills.

One or two, three times a day, as a nervine stimulant in cases of hysteria, accompanied with flatulence. Good musk costs half-a-crown a grain.

VAGINAL INJECTION.

Alum, 1 drachm;
Sulphate of Zinc, 1 drachm;
Permanganate of Potassium, 1 grain;
Heliotropin, 1 grain.

The powder to be dissolved in a pint of warm water and used as a vaginal douche.

FUMING INHALATION.

Powdered Stramonium Leaves, 1 ounce;
Powdered Anise Fruit, half-an-ounce;
Powdered Fennel Fruit, half-an-ounce;
Black Tea in Powder, 1 ounce;
Iodide of Potassium, 1 ounce;
Nitrate of Potassium, 1 ounce.

The fumes of the burning powder will afford relief in the paroxysm of asthma and will often induce sleep in cases of insomnia.

PHYTOLACCA GARGLE.

Tincture of Phytolacca, 4 drachms;
Carbolic Acid, 5 minims;
Dilute Acetic Acid, 2 drachms;
Tincture of Myrrh, 1 drachm;
Eau de Cologne, 2 drachms;
Water to 8 ounces.

Useful in the Catarrhal Laryngitis from which singers and public speakers so frequently suffer.

CHLORAL AND CAMPHOR LINIMENT.

Chloral Hydrate, 1 drachm;
Menthol, 1 drachm;
Camphor, 2 drachms;
Chloroform, 2 drachms;
Sulphuric Ether, 1 drachm;
Tincture of Aconite, 1 drachm;
Oil of Origanum, half-a-drachm;
Oil of Sassafras, half-a-drachm;
Rectified Spirit to 4 ounces.

The chloral menthol and camphor should be rubbed up together and then mixed with the oils, after which the other ingredients should be added. It is a useful liniment in cases of rheumatism and neuralgia. It should be used cautiously and should be labelled "Poison."

Transactions of Societies.

OPHTHALMOLOGICAL SOCIETY OF GREAT BRITAIN.

MEETING HELD THURSDAY, JANUARY 30TH.

The President, Mr. NETTLESHIP, F.R.C.S., in the Chair.

THE VISUAL EFFECTS OF REFRACTIVE ERROR.

Dr. G. J. BULL said it is rare to meet with a person whose refraction did not in some degree vary from the normal, and every such error unless cancelled or corrected must, of course, produce some deformation of the normal visual image. Hitherto, however, it had been the custom to think of all such deformations simply as diminutions of the normal acuity. It had occurred to him to analyse more closely what really happened when the acuity of a patient, so far as the ordinary test types were concerned, was found to be diminished to a greater or lesser degree by refractive error. He had, therefore, endeavoured to reproduce with the help of the photographic camera pictures of the test types, and also of objects in nature as they would be seen by patients suffering from given errors of refraction. This, he thought, could be done by taking photographs with the plate more or less out of focus to represent the vision of myopes and hypermetropes, and with the lens of the objective obliquely inclined to show the distortion of astigmatia. Subsequently however he adopted the easier plan of attaching the spherical and cylindrical lenses of his trial case, to the objective of the camera. The result had been to fix upon the photographic plate a very curious and interesting record of many of the features of ametropic visual error applicable to the most diverse forms of objects and the most diverse conditions of sight, but at the same time it showed that the ametropia of the camera exhibited certain characteristic features. To begin with the well-known phenomenon of "doubling" he said it was not uncommon to find patients who, on looking at the test types, saw two lines of type instead of one. The actual doubling was usually observed only where the object was a line of relatively small dimensions or a simple system of such lines, in fact the troubled vision in such cases appeared to be due to imperfect superposition of a series of faint multiples of the original letter. He had tested his photographs carefully in various ways by comparing them with the appearances which are observed by an eye in which the corresponding refractive error had been artificially produced by arming it with the appropriate lenses. In thus comparing the photographs he had been enabled to observe more closely than hitherto the action of certain sources of error which were of considerable practical importance. He remarked that the apparent higher acuity of the eye armed with a given lens as compared with the camera with the same lens placed in

contact with the objective, was the result in great part of certain habits and characteristics of the eye which were either always present or were so difficult to guard against that even the most cautious observers were more or less affected by them.

The PRESIDENT observed that if the phenomenon of monocular doubling were as universal as the author supposed, it was curious that patients did not more frequently direct attention to the fact.

Mr. FROST said he had come across these cases in rotations, and he employed a special method, consisting in rotation of a long line, in order to discover if the patients really saw double.

Dr. BULL, in reply, thought everyone exhibited this phenomenon if only it were looked for. People were usually bad observers, and, moreover, they did not look at objects well calculated to show it up. Formerly he thought it was a phenomenon of advanced life, but a large number of recent observations have satisfied him that it might always be found even in children.

CASE OF UVEAL CYST OF IRIS.

Drs. EALES and SINCLAIR related the case of a man, *æt.* 47, who came with the left eye in a condition of absolute glaucoma, the result of chronic non-inflammatory glaucoma of some years' standing. Extending into the pupillary area from behind the iris were two dark brown globular masses. These moved freely with every movement of the eyeball, and on close examination with a magnifying glass a fine jelly-like quiver of the surface of each mass was noted. The diagnosis of cystic detachment of the posterior uveal layer of the iris was made, and this was fully borne out by pathological examination. This was, so far as they were aware, the first case in which cystic detachment of the uveal layer of the iris had been diagnosed clinically, though they had records of other published cases in which this condition was probably present. They wished particularly to direct attention to the fine creasing and quivering of the cyst wall as a diagnostic sign between this condition and pedunculated sarcoma of the iris.

Mr. TREACHER COLLINS said it was a common thing, in eyes with old inflammatory trouble, to meet with slight detachment of the pigmentary layer at the back of the iris. This case, however, belonged to a somewhat different category, because it was non-inflammatory. In a case which he figured in his own paper, the cyst was in the same situation. This was a case of melanotic sarcoma of the ciliary body and the whole iris was cedematous.

Dr. EALES thought the absence of the lens was due to absorption and not to congenital deficiency.

OPTIC ATROPHY IN THREE BROTHERS.

Dr. F. M. OGILVIE commenced by the remark that the title of "optic atrophy in three brothers" had the advantage of avoiding the vexed question of heredity, and though he believed these to be cases of Leber's hereditary optic atrophy he had been unable to prove that they were anything more than collateral atrophies. The father and the three sons, the only living males, were all employed in some large engineering works in Suffolk. Case 1: W. J., *æt.* 24, attended Moorfields in October, 1887. He had always been in good health and temperate in respect of alcohol. He had smoked since he was 18, four ounces of "shag" a week. Sight was good up to July, 1887, and at that date, having gone to bed seeing as usual, he awoke hardly able to find his way about. R V 6/0 L V 6/0, pupils acted to light. With the ophthalmoscope the optic disc appeared a little pale on the temporal side, the rest being a full colour. There was slight oedema and thickening of the sheaths of the arteries on the disc. The veins were over full and tortuous even to the small branches. There was a deep physiological cup. Colour vision was very defective and there was not a very well-defined central scotoma colour. The fields for white were full. He was treated for three months at Moorfields and when discharged vision was R 3/80 L 6/0. Jaeger 16 at 4". Seven years later his condition was found to be practically unchanged. Case 2: A. J., *æt.* 22, attended the Westminster Ophthalmic Hospital in June, 1894. Good health up to commencement of visual failure. He had been temperate, but had smoked since 18 years of age, on an average, 1½ ounces of "shag" a week. In March, 1894, he first noticed a difficulty in seeing small print. Coinci-

dently with this, he suffered from severe pains in the head of a sharp shooting character, chiefly confined to the temporal regions, and worse at night. He had had no headaches before this date. In May he was obliged to give up his employment. His sister stated that he had been "strange in his manner" for two weeks. Vision R 6/60, J 20; L 6/60, J 16, pupils acted. The disc was of a good colour, but the vessels were extremely tortuous, some of the vessels dipping antero-posteriorly, as well as curving on the flat. The veins were over full. There was a peripheral patch of superficial choroidal atrophy, with slight pigmentation, symmetrically placed in both eyes. Refraction emmetropic. The fields for white were contracted. Three months later his vision had gone down to hand movements only, but he could pick his way about in a crowded waiting room pretty easily. The fields for white, repeatedly taken, had always shown concentric contraction, not always constant in degree. There was a central scotoma for white, and his colour vision was extremely defective. The discs were now white all over. The former headaches have now entirely left him. He has not smoked for 18 months. Case 3: A. J., *æt.* 27. He examined this patient in February, 1895, for the purpose of comparing him with his two brothers. He then had excellent vision, according to his statement, but on testing, it proved to be R 5/24 on both sides. J 2 at 11 cm. with great difficulty. There was no blurring of the disc margin, but the vessels were very tortuous. Refraction was slightly myopic. When he came to the hospital, seven months later, he said he had been subject to headaches with vomiting ever since he could remember. He said his mother suffered in the same way, and he described them as "bilious." He was temperate, but had smoked since 18 years of age, at first 1 ounce of shag a week, afterwards increased to 2 or 3 ounces. In March of this year he reduced the quantity to about half an ounce a week. He dated the commencement of failure of vision from the beginning of last March. This got steadily worse, and in September he had to give up work. R 2/60, L 3/60, J. 20. Both discs were rather pale, the outer half most so, there was a large physiological cup, the vessels were normal in size, but very tortuous. Fields for white full, ill-defined central scotoma for colours in each eye. Could match wools slowly, but correctly. He was treated for nine weeks, and improved to R 5/60, J. 18, L 6/24, J. 18. Both optic discs were very atrophic. He had not smoked for five months. The author pointed out that all these patients were attacked early in adult life. They had all been moderate in respect of alcohol, and they were all smokers of shag tobacco, though not in large quantities. There is no history of acquired syphilis and no trace of hereditary syphilis. No history of sexual excess or abuse. Headache was absent in Case 1, coincident with failure in Case 2, ceasing on its failure reaching its maximum. Occasionally from childhood in the third, and relieved by vomiting. The onset of visual failure was gradual in Cases 2 and 3, sudden in Case 1. The amblyopia was equal in both eyes in all the cases. The father, *æt.* 57, was an orphan, parents unknown. V 6/9, retinal vessels not tortuous. The mother, *æt.* 53, was the youngest of ten children, five males and five females. No history in her parents of defective vision. Three of the five brothers died unmarried, the two married brothers have two and seven children, no history of defective vision. Of the four sisters, three died unmarried. The eldest had only one child, a male, sight not defective. Mrs. J., had V 6/12 and presented tortuous vessels, a condition which prevailed throughout the entire family, with the exception of the father. She has had 16 pregnancies with two miscarriages. Of the 14 children born alive, eight died in infancy, none of them surviving more than six months. This mortality did not resemble that resulting from syphilis in that it was irregularly distributed. None of the children present any evidence of hereditary syphilis. Of the six living children the three males were the subjects of this paper. Of the three females there was little to note. They all presented the tortuous vessels and one of them suffered from fits, probably hysterical.

Dr. HABERSHON remarked that one of the only two cases of the kind he had seen also presented patches of choroidal atrophy at the periphery, and, as in the author's case, there was no history of syphilis.

Dr. EDGAR BROWN said he had recorded a number of these cases in the Transactions, but unfortunately they were not

worked out from a family point of view. All the cases occurred in smokers. He thought that something was required to determine the optic atrophy, for people could scarcely be born foredoomed to optic atrophy without any cause in the way of disease or foreign influence. These cases associated with the use of strong tobacco, presented certain peculiarities. They went on for years without further impairment of vision, and when examined they almost always showed evidence of the previous existence of a central scotoma, evidence, that is to say, that the disease began as an axial neuritis, and not as peripheral neuritis. In ordinary optic atrophy the tendency was for the vision to become progressively and surely less, and the central deficiency was not marked as in the tobacco cases.

The PRESIDENT said it was extremely desirable that cases of this condition occurring in non-smokers should be placed on record.

Mr. JOHNSTON TAYLOR said he had recorded some cases in a family of 11, and they were all in the smoking members of the family. It occurred to him that violent counter-irritation in the early stages might be productive of moderately satisfactory results. He noted that in the youngest case improvement followed opening of the mastoid antrum for middle ear disease, and in any case energetic treatment could do no harm.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

MEETING HELD FRIDAY, JAN. 10TH, 1896.

The President, Sir W. THORNLEY STOKER, P.R.C.S., in the Chair.

COMPLETE EXCISION OF THE LARYNX, WITH SUBSEQUENT POWERS OF VOCALISATION.

MR. R. H. WOODS showed a man whose entire larynx had been excised in 1892 by Dr. Solis Cohen, of Philadelphia. The trachea opened externally in the middle line of the neck in front, and there was no communication whatever between the mouth and the respiratory organs. The man was, however, able to vocalise. Mr. Woods believed this was accomplished by gulping air into the œsophagus, and that this air was forced up again by pressure from below. The sound was made by muscular fibres or bands in the œsophagus, which had gradually been trained to perform this function. The case elicited a great deal of interest.

A CASE OF OPERATION FOR PULSATING TUMOUR OF THE TEMPORAL REGION OF TWENTY YEARS' STANDING.

Prof. C. YELVERTON PEARSON (Cork) showed a photograph and read a report of a case of pulsating tumour of the left temporal region, on which he had successfully operated in October, 1894. The tumour occupied the entire temporal fossa, and was bound down by the temporal fascia. With the exception of a few fibres, the temporal muscle had disappeared. In structure it consisted of a convoluted mass of dilated and tortuous thin-walled blood vessels, which were so fragile that they would bear neither ligature nor compression with forceps. The entire mass, owing to the great severity of the hæmorrhage, was cut away with the Paquelin's cautery-knife, which had also to be inserted into a fissure in the coronal suture, through which large vessels of communication passed. The tumour, which probably originated from a head-injury, had been nearly twenty years in existence, and the operation was undertaken at the earnest solicitation of the patient owing to the increasing severity of the symptoms, which consisted of intense pain either on stooping or throwing the head back, insomnia, dizziness, throbbing sensations, and inability for occupation. The aneurysm was supplied chiefly by the middle, meningeal, and deep temporal arteries. The patient is now in excellent health, has no pain or other disagreeable sensation, and sleeps well.

The PRESIDENT thought that it was not possible to form a diagnosis with any great degree of certainty. He mentioned the case of a girl, aged seventeen, with a pulsating tumour at the junction of middle and lower third of thigh. The tumour had a connection with the bone. There was tremendous hæmorrhage, to check which pressure on the femoral trunk above the tumour was ineffectual. The

tumour was supplied from blood vessels in the bone. He thought amputation at the hip-joint was the right proceeding in such a case.

Dr. BENNETT congratulated Prof. Pearson on his case. He would like to know from Prof. Pearson whether (1) there was any *bruit* heard previous to operation; (2) whether pressure on the carotid was carried out with a view to stopping the bleeding? Pressure on the common carotid could be kept up so completely under anæsthesia that it would control the hæmorrhage, at least for a time. Pressure in Sir T. Stoker's case would be of no use, but things were different in tumours of this kind occurring in the head.

Mr. KENDAL FRANKS congratulated Prof. Pearson on his extremely interesting case. He asked what was the condition of the bone. From what he could gather there was a fissure in the bone, through which fissure a circoid aneurysm existing within the skull was continuous with a similar aneurysm outside it.

Mr. THOMSON thought that one of the most interesting features of this most interesting case was its subsequent history, as detailed by Prof. Pearson. He took it, of course, that what was removed was only part of the tumour, for, from what he could gather, he believed there was a tumour within the skull, perhaps not so large, but of the same character as that which appeared outside. Now, when Prof. Pearson removed the outer portion of the tumour, what became of the inside portion if it was of the same character? What happened in Prof. Pearson's case probably was, the sealing up of the vessels on the outside had the effect of what was called distal ligature. Prof. Pearson's difficulty with the hæmorrhage was in the fact that the tumour was fed by vessels inside the skull. He knew the difficulty of getting ligatures to hold in those cases, but he was not sure that the application of the cautery would be a reliable method in the next case.

Prof. PEARSON, in reply, expressed his thanks to the Academy for the kind manner in which his paper was received. In reply to Prof. Bennett, he said there was no *bruit* present. Compression of the common carotid was resorted to to check the hæmorrhage. He regarded the case not as one of pulsating tumour of bone, but as a case of aneurysm by anastomosis. He regarded the intracranial aspect of the case as very serious. He believed, with Dr. Thomson, that there was a free communication between the aneurysm inside and that outside the skull. He mentioned that, in his case, the bones were sound, though much thinned. The arteries coming through the squamous portion of the temporal bone were much dilated.

TUBERCULAR DISEASE OF THE HIP JOINT.

Mr. SWAN read a paper on this subject. He reviewed the pathology of the affection, and quoted statistics from the Orthopædic Hospital to show the comparative frequency of hip-joint disease in hospital beds, as opposed to spinal affections, which, although positively more numerous, are capable of being treated more easily in their own homes. This he accounted for by the greater frequency of suppuration and its consequences, in hip cases. He reviewed the various deformities incidental to the disease and their mechanics. He deprecated the procedure of removing a tubercular deposit in the trochanter or neck of the femur, as a routine, for a variety of reasons—the difficulty of accurate diagnosis, the danger of sepsis, and the retrogressive changes tending towards cure, being a few.—He showed an ingenious arrangement for easily adapting a stirrup extension, and went at some length into the application of that remedy.

The PRESIDENT said that if ever there was a paper calculated to elicit discussion it was this. The paper was one of great ability and the result of great practical experience. One of the most interesting matters put forward by Mr. Swan was his dissertation on the existence of tubercle in parts other than where it exhibited itself. That was a question on which they now felt certain. There was another matter on which he entertained a growing opinion, and that is that in the great majority of cases of tubercular spine disease the bones are the centres of the affection. The disease of one joint—the knee—confirms him in this opinion. Many cases, known clinically as tubercular synovitis, in reality belonged to the osteal class; and abscesses regarded as of the soft parts were old tubercular abscesses, originating in bone.

Prof. C. Y. PEARSON supported the statement of the President, that most of the cases regarded as tubercular disease of the synovial membrane have really their origin in the bone.

Mr. KENDAL FRANKS thought that the bone was generally the starting point of tubercular mischief. He had for years given up the operation of arthroectomy. In cases of knee-joint disease, where the ends of the bones looked healthy and the disease seemed limited to the soft tissues, section of the bone generally showed an abscess in the condyle of the femur or head of the tibia.

Mr. THOMSON was very strongly of opinion that in the vast majority of tubercular diseases of joints, the cause was due to injury. But in many cases the injury was so slight that it was not complained of until damage had been done to the bone.

Dr. CHANCE congratulated Mr. Swan on his paper. The only point on which he differed from him was in regard to his treatment by adduction. He thought Mr. Swan's method of extension an excellent one, but inferior to extension by a wire splint he described.

Mr. SWAN thanked the meeting for the manner in which they had received his paper. The speakers, he said, were unanimous in their condemnation of arthroectomy. He, too, condemned it.

LARYNGOLOGICAL SOCIETY OF LONDON.

ANNUAL GENERAL MEETING, JANUARY 8TH.

DR. FELIX SEMON, President, in the Chair.

THE Reports of the Council and Treasurer, which were read and adopted, showed that the Society was in a very flourishing condition, there being now over a hundred members belonging to the Society, and the financial statement showed a very satisfactory balance in hand. The following were elected to serve as Officers and Councillors for the ensuing year:—President: Felix Semon, M.D.; Vice Presidents: E. Creswell Baber, M.B., A. Hodgkinson, M.D., Charters Symonds, F.R.C.S.; Treasurer: W. Johnson Walsbam, F.R.C.S.; Librarian: E. Clifford Beale, M.B.; Secretaries: W. R. H. Stewart, F.R.C.S., St. Clair Thomson, M.D.; Council: J. B. Ball, M.D., F. W. Bennett, M.D., J. W. Bond, M.D., Scanes Spicer, M.D., and F. Watson Williams, M.D.

At the subsequent ordinary meeting the following cases were shown:—

Case of Bilateral Abductor Paralysis of the Vocal Cords in a case of bulbar paralysis complicated by progressive muscular atrophy, by the PRESIDENT. The patient, a man, *æt.* 54. Duration of illness 16 months; commenced after influenza with difficulty in swallowing and articulation, followed by progressive weakness of right arm and leg. There has been ever since a gradual progression of the disease. On Nov. 12th the following note was made: During quick respiration the vocal cords stand nearer one another than under ordinary circumstances. On deep inspiration no further opening of the glottis takes place. Movements of the left cord are distinctly more defective than those of the right. On phonation complete closure of the glottis occurs.

Case of Myxo-Chondroma of Larynx, by Dr. BOND. A man, *æt.* 50, had the whole larynx removed in September, 1892, the tumour weighed 11½ drachms. Eight days after operation the patient eat a chop. Has worn an artificial larynx for 39 months. There is no sign of recurrence.

Case of Epithelioma of Larynx, by Dr. BOND, for Mr. HARVEY. On August 14th, 1894, the whole larynx was removed, together with numerous glands. Two plastic operations were performed later on to cover the gap above the site of the artificial larynx. There is no sign of recurrence.

Case of Clonic Spasm of Pharynx and Soft Palate, by Dr. BOND. Patient, a man, *æt.* 33. The pharynx moves in a rapid, rhythmical manner from side to side, and the left side of soft palate is drawn up and down. The patient had no idea the throat was affected.

Dr. C. BRALE considered that corea of pharynx was a misnomer.

Specimen of Nasal Polypus of Unusual Size removed from the Naso-Pharynx of an Adult, by Dr. BRONNER.

Case for Diagnosis, by Dr. COOPER CRIPPS. W. S., *æt.*

t0, presents a smooth elastic swelling about half the size of a hazel-nut on the left side of the thyroid cartilage of several years' growth; larynx normal, but there is a considerable increase of the lymphoid tissue at the base of the tongue.

Mr. C. SYMONDS thought the case one of either a thyroid or a hyoid cyst.

Microscopical Specimens and Drawings of two Cases of Malignant Disease of Tonsils, by Dr. DAVID NEWMAN. One was a case of epithelioma of left tonsil; left posterior pillar and uvula in a man, *æt.* 55. The other one, of carcinoma of left tonsil and soft palate in a woman, *æt.* 51.

Mr. C. SYMONDS congratulated Dr. Newman on his success in these cases, and asked how he had operated, if it were possible to do so through the mouth alone? Recurrences so frequently occurred in the glands that he had determined to dissect out the neck whether or no the glands were enlarged.

Dr. NEWMAN, in reply, stated that in one case under cocaine, and in the other under chloroform, he had removed the growth and a large amount of healthy tissue around with the galvano-cautery.

Two cases of Tubercular Laryngitis in which complete recovery took place, by Dr. DAVID NEWMAN. Both were cases of primary tuberculosis of the larynx in which the lungs became secondarily affected. One was *æt.* 29, the other, 19. The treatment adopted in both cases was a carefully regulated diet, a warm moist atmosphere impregnated with menthol, terebene and eucalyptus, spraying the larynx with cocaine, and when sufficient anaesthesia was produced, a spray of a concentrated solution of iodoform in equal parts of alcohol and ether was used—at first twice daily—and afterwards three times a day.

Case of Abductor Paralysis with Laryngeal Crises, by Mr. C. A. PARKER. W. W., *æt.* 32, a porter, woke up one night three or four years ago with difficult breathing, became worse, and suddenly lost consciousness, and remained so for two minutes, when he recovered he could breathe quite well. Had five other similar attacks at intervals of six months. Examination showed left vocal cord fixed in the middle line right did not abduct beyond cadaveric position; no knee-jerks, gait unsteady, no history of syphilis. Laryngeal symptoms still remain the same; tabetic symptoms more marked.

Microscopical Sections of Warty Growth of Suspicious Nature on Left Vocal Cord, by Dr. SCANES SPICER. Patient was shown at November meeting. Growth was removed under cocaine. Histological report by Dr. T. H. R. Crowle showed the nodule to be of inflammatory origin, the inflammation evidently being of a very chronic and long duration.

Case of Fibroma (? Fibro-sarcoma) of Cartilaginous Septum with microscopical section, by Dr. ST. CLAIR THOMSON. Patient, *æt.* 29, suffered from epistaxis off and on for some years. An irregular ovoid lobulated growth growing from the cartilaginous septum was removed from the right middle meatus with a snare, three weeks after there was distinct proliferation of the root.

Mr. SPENCER did not think that it was distinctly sarcomatous.

Mr. SYMONDS, Dr. NEWMAN, Mr. WAGGETT, and Mr. STEWART thought it was a sarcoma. At the suggestion of the latter it was sent to the Morbid Growths Committee.

Case of Inter-arytenoid Pachydermia laryngis, by Dr. H. TILLEY. Patient was shown last year. Under an application of an 80 per cent. solution of lactic acid her condition was much improved.

Laryngeal case for Diagnosis, by Dr. H. TILLEY. Patient, a man, *æt.* 51, has granulation masses on the vocal processes lasting twelve months. Vocal cords are movable—larynx very red and congested.

The PRESIDENT thought it was either syphilitic or an ordinary inflammatory growth.

Case of Probable Intrinsic Carcinoma of the Larynx, by Dr. DUNDAS GRANT. J. W., *æt.* 45, had hoarseness and difficulty of breathing for two years. Examination showed a distortion of left side of epiglottis, swelling and immobility of left arytenoid, left ventricular band red and infiltrated, and below it covering the greater portion of the cord, a pale granular swelling.

The PRESIDENT suggested immediate thyrotomy and thorough removal of contents.

THE DERMATOLOGICAL SOCIETY OF GREAT
BRITAIN AND IRELAND.

MEETING HELD WEDNESDAY, JANUARY 22ND.

The President, Dr. PYE-SMITH, in the Chair.

THE PRESIDENT showed a well-marked case of the rare condition known as

MYCOSIS FUNGOIDES.

The patient, a man, *æt.* 27, had suffered from the affection for three years. He was improving somewhat under the application of iodoform powder and a strong lead lotion, and, so far, had not suffered in general health. Dr. Pye-Smith remarked that this was the *mycosis fungoides* of Alibert, and others would call it a sarcoma, but he should be inclined to call it a *granuloma fungoides*. In another case he found sections of the tumour resembled a round-celled sarcoma.

Dr. DAVID WALSH showed a case of Symmetrical Shin-Baldness occurring in a man, who for the past two years had areate patches on the scalp, chin, and sides of the larynx. The patient stated that the hair was formerly so long over the shins that he was "able to comb it." There was some irritation in front of the legs, and the hair fell off shortly before the bald patches appeared on the head. Dr. Walsh remarked that this case must be regarded in the light of a preliminary communication. A slight investigation showed that the normal distribution of hair on legs varied considerably. In some places the hair became rubbed off by the friction of clothing. That fallacy, however, appeared to be excluded in the case shown before the Society, as the man wore drawers and socks. He had found another similar case of shin-baldness in a patient at the Western Skin Hospital, who also suffered from alopecia areata of the scalp. Mr. Waren Tay had also observed a case at Blackfriars. In these cases symmetry was worthy of special notice, as pointing to a possible tropho-neurotic origin. If alopecia areata be a tropho-neurosis, as maintained by Kaposi and others, and if this shin-baldness be connected with the scalp condition, then we had in that definite symmetrical affection a factor of value bearing on the theory of neuro-pathogenesis. Shin-baldness might possibly be connected with the class of cases mentioned by McCall Anderson and others, in which vitiligo supervened on the alopecia areata. The case was brought before the Society as suggestive of future inquiry. Any observation on alopecia areata seemed worthy of attention, because of the difference of opinion that existed among dermatologists as to its real nature and origin.

Dr. WALSH also showed a case of Alopecia Areata in a woman, *æt.* 39, in which the bald patches had been present for nine years. Some of them had become covered with hair, but others showed a deep atrophic condition, and the scalp in those places resembled a tender subcutaneous cicatrix. There had been a history of severe long-continued neuralgias and migraines. The condition appeared to be a mixed one, due to (1) alopecia areata, with associated sensory changes; (2) chronic seborrhoea capitis; (3) atrophy of subcutaneous tissues. Latterly the patient had developed pediculi capitis, and had become sallow and lost flesh.

Dr. WALSH showed a woman, *æt.* 43, with a well-marked Seborrhoeic Dermatitis on the Body and Legs. The rash began on the abdomen. It consisted of numerous papules, rings and gyrate fawn-coloured patches; the rings were raised at the edges, which were formed of small papules, and coalesced in places. There was little irritation with the rash, which had lasted four or five weeks, and was yielding rapidly to local antiseptic treatment. There was an associated seborrhoea of the scalp, which was dry, scaly, and irritable, while the hair was thin, dry, and lustreless. The chief point of interest about the case, assuming it to be a seborrhoeic dermatitis, was its occurrence on the legs. In speaking of this affection Dr. Crocker said, "the limbs, except where they join the trunk, are never affected."

Dr. ABRAHAM said that two years since he drew attention to the common occurrence of shin-baldness in alopecia areata cases, which he attributed to seborrhoea, tinea, and nerve lesions. He concluded at the time there was no connection between the two conditions.

Dr. BOWLES mentioned a case in which the hair suddenly fell off both legs after some little itching. The condition was limited to the legs.

Dr. EDDOWS did not recognise the term seborrhoeic dermatitis. The case shown by Dr. Walsh he should call the seborrhoeic eczema of Unna, an affection which commonly attacked the limbs.

Dr. PYE-SMITH pointed out that Unna had extended the term seborrhoea far beyond the limits usually adopted by English dermatologists.

Dr. ABRAHAM showed a boy suffering from Keratosis Follicularis. Numerous patches of grouped comedones appeared on the back, thighs, and legs. A few were scattered here and there over the face. There was a history of pediculi corporis.

Dr. Savill showed two young women from Mr. Tay's Clinic at Blackfriars. Both exhibited recurrent, chronic, and relapsing patches of erythema on the face. In one instance the condition had quite cleared up at times under the use of thyroid gland.

Dr. STOWERS showed a boy suffering from Congenital Ichthyosis. He was nine years of age, and had been affected since he was five months old. There was no family history.

Dr. ABRAHAM found thyroid had a better effect in this condition than in psoriasis.

Dr. MACKAY advocated the inunction of simple vaseline and the use of thyroid gland. He asked if any members knew cases among good class patients.

Dr. PYE-SMITH mentioned a severe and chronic case in an Eton boy.

Dr. STOWERS showed two syphilides, one of which had a psoriasis-like patch on back. He also showed a patient with a hypertrophic or verrucose eczematous patch on the leg, and other cases.

Dr. PERNET announced a short paper with some further details as to the etiology of acute pemphigus.

A paper by Dr. Eddowes on Warts of the Feet was deferred owing to want of time.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, Feb. 1st, 1896.

MORPHINOMANIA.

At the Academy of Médecine, M. Laborde read a report from a colleague on the treatment of 57 cases of morphinomania by rapid suppression of the drug. Of the total number of persons addicted to this habit, 24 were women, and amongst the men were 15 doctors. The ages were between twenty-five and forty. In the majority of cases the habit was contracted by using, at first, the morphia for therapeutic purposes, and the doses ranged from 2 to 40 grains. Alcoholism was present in six cases, while cocaine was taken concurrently with the morphia in eight instances. Of the 57 patients, 38 were followed up since their cure. Six of these persons relapsed, and three of them returned to submit to the treatment, proving that the suffering attributed to the rapid suppression of the drug was not so frightful as was supposed.

To resume, the author of the report and of the treatment estimates that the method of rapid suppression guarantees against relapses, provided that the patients consent to remain under treatment two months; that the method did not require any physical contention, and that it provokes neither mortal accidents nor violent pains, as are sometimes reported where the suppression was sharp.

ABSCESS OF THE LIVER.

M. Ricard read, in the name of an absent member, a paper on the treatment of hepatic abscess before the Surgical Society. Of the six cases reported three were consecutive to chronic dysentery. The purulent collection in each case was seated behind, necessitating a large resection

of the ninth and tenth ribs. In the remainder of the cases the incision was made in front, and the coverings attached to the walls of the wound to enable the purulent cavity to be well washed out after section. Some of the patients recovered, only in one case did a fistula persist a short time.

EXTRA-UTERINE PREGNANCY.

M. Picqué read an account of three cases of uterine pregnancy. The first case was that of a woman of thirty-three who entered the hospital for obstinate menorrhagia. A closer examination revealed the existence of pregnancy in the right tube. Vaginal hysterectomy was performed, and the patient rapidly recovered. The second case was somewhat similar, but the third was more interesting, in that the fœtus had already attained seven months when its abnormal position was discovered. The condition of the patient being very critical, it was thought better not to defer interference, laparotomy was performed, and the fœtus extracted without difficulty. The placenta was not touched.

In commenting on these cases, M. Picqué said that confusion frequently occurred between hæmatocele and extra-uterine pregnancy, many thinking them to be one and the same thing, whereas they are absolutely distinct. As regards intervention in extra-uterine pregnancy, everyone was agreed on the necessity of removing it each time it was diagnosed at its commencement. Where it was four or five months old, and where the mother suffers no inconvenience from the abnormal position, a chance might be given to the child. The accidents always to be feared in these cases are rupture and hæmorrhage.

EXTRA-UTERINE PREGNANCY.

The last meeting of the Société Chirurgicale was entirely devoted to the discussion on the treatment of extra-uterine pregnancy.

M. Routier, who was the first to speak, said he thought they were pretty well agreed on the fact that there existed only one treatment for extra-uterine pregnancy, and that was laparotomy. For his own part, and with a view of diminishing the danger for the mother, he would not allow such cases to arrive at the seventh or eighth month of their evolution. There were cases where the abdominal tumour was difficult to diagnose, and where one hesitated between a simple cyst, a fibrome, a dermoid cyst, a salpinx, or an extra-uterine pregnancy. It was only by the attentive study of the concomitant phenomena that a correct diagnosis could be arrived at. It was thus that he was able in four cases to arrive at a correct opinion, operate, and save his patients. The first case was a pregnancy of five months; by laparotomy the whole cyst was removed with its contents, the patient recovered quickly, and two years after was confined normally. In the second case the pregnancy was about three and a half months, when he had opened the abdomen he found that the fœtal cyst was enclosed in a large cavity of hæmatocele, in the middle of which floated the extremity of the Fallopian tube greatly thickened by inflammation. The hæmatocele was situated in the right iliac fossa, and was only limited by the intestines bound together by false membranes. The third case was somewhat similar. He had treated a patient by rest after curettage for hæmorrhagic metritis in February, 1894. On the 3rd July following, she was seized with a violent pain in the abdomen, and entered the hospital. The uterus was found to be fixed by a large tumour, being to the Fallopian tube on the left side. A few days

afterwards, by laparotomy he discovered that the tube had given way close to its insertion into the uterus, and that a large hæmatocele had formed around the fœtal cyst. The fourth and last case presented no striking feature.

Although cases of extra-uterine pregnancy presenting all the symptoms of an abdominal tumour, and more or less easy to diagnose, are far from being rare, much more numerous are those of retro-uterine hæmatocele. He did not refer to those cases which suppurate, although he was satisfied that the greater number of large retro-uterine abscesses had no other origin. Of 126, in which he had to interfere, he would only speak of 24 cases of hæmatocele which he had opened through the vagina, removing black clots, and with them, in three instances, a fœtus from five to ten inches long. In one of these cases, notably, he diagnosed a retro-uterine hæmatocele in a woman of thirty-one, in whom the menses had been suppressed already two months. He incised the tumour in the posterior cul-de-sac, and removed a quantity of black clots, and although he thought he had felt a fœtus he could not find it. Fearing hæmorrhage he did not dare to remove all the clots and placed two drainage tubes in the cavity. Twenty days afterwards a fœtus of six inches long came away with an injection. He lost none of the twenty-four patients thus operated, although in one case the hæmorrhage was so serious as to necessitate compression of the aorta, while the cavity was being plugged. In concluding, M. Routier said that when the hæmatocele had not yielded, after four or five weeks, to absolute rest in bed, ice on the abdomen, hot injections, and repeated purgatives, the tumour should be incised through the vagina, without, however, scraping too much the walls of the cavity for fear of hæmorrhage. Laparotomy should be reserved for the abdominal tumour leading to believe the existence of an extra-uterine pregnancy.

M. Schwartz said he agreed entirely with his learned colleague. When a surgeon was in presence of a still unbroken tubal pregnancy and which might be taken for a salpingitis, laparotomy was the only operation to be thought of. When an hæmatocele followed a rupture of the tube and that the tumour pointed in the abdomen, the same operation was indicated, while the vaginal incision was reserved for those cases where the tumour was felt in the posterior cul-de-sac.

M. Segond spoke on the complications of extra-uterine pregnancy of which the most dangerous was hæmorrhage into the peritoneal cavity, and for which laparotomy should be performed without delay. Where the hæmatocele was found behind the uterus incision through that part should be made, and the clots removed, paying no attention to the placenta. Where the hæmatocele suppurated vaginal hysterectomy was indicated.

At a recent theatrical performance given by Sir Henry Irving and Miss Ellen Terry and their Company for the benefit of the Jefferson Maternity Hospital, Philadelphia, the large sum of £600 was realised.

In consequence of the prevalence of diphtheria in Strood, the sanitary authorities have decided to close the Strood Hill Schools for three weeks.

DR. G. HERBERT HOPKINS, of Swansea, who is about to leave for Brisbane, Australia, was last week presented with a purse of gold subscribed by his fellow practitioners in the town.

THE NEW PHOTOGRAPHY.

SHADOW PHOTOGRAPH OF A LIVING HAND.

THE above photograph (for which we are indebted to the Royal Photographic Society) was produced by Mr. J. William Gifford, with an exposure of ten minutes. In it the bones and their articulations will be readily seen, the peculiarity of the Röntgen discovery being exhibited in the penetration by the rays of the fleshy portion of the hand, and its almost entire absence in the photograph. Thus, the ring on the second finger stands prominently out, as though no flesh were there to support it. The influence of this discovery on the surgery of the future can only be vaguely imagined in these early days; but its utility in the search for bullets, splintered bones, and foreign bodies is already assured.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, Feb. 1st.

IODINE IN THE THYROID GLAND.

BAUMANN recently reported that he had found iodine in large quantities in the thyroid glands of sheep and pigs, and also in the human subject, and that the quantity amounted to 10 per cent. Hr. Ewald, at the meeting of the Society for Innere Medizin noted that as this iodine must also be present in dried preparations of the gland he had, therefore, made an examination of the English thyroid tablets. He examined 12 of these by Baumann's process, and arrived at results identical with those of the discoverer, i.e., the tablets also contained a large quantity of iodine.

RONTGEN'S RAYS AGAIN.

Hr. Jastrowitz, of whom I wrote in my last, again appeared before the same society, and showed a negative that had been taken by Hr. Spies, Director of the Physical Department of the Urania. The photograph represented a piece of lead of an inverted V shape that lay inside a wooden box.

Hr. Gluck reported on a series of cases of

EXTIRPATION OF THE LARYNX.

The cases were 13 in number, and in all the operation was performed on account of malignant disease. In some the extirpation was only partial; six of the cases died and seven recovered and remained a long time free from return of the disease. Considering the dangers of the operation—cardiac paralysis, pneumonia in consequence of severance of the recurrent nerve, and septic infection—were good. As regarded technique, the tampon cannula of Trendelenburg, and Hahn's cannula were of great service. Three years ago the speaker had proposed a method of operation whereby these appliances would be rendered unnecessary and the after treatment easier, viz., the preliminary transverse section of the trachea, and the drawing of it out, with the insertion of a cannula. After extirpation the larynx was tamponnaded. The method had been adopted in France and carried out frequently. He then showed a patient who by means of an artificial larynx could speak quite distinctly.

Dr. Gottechalk then showed preparations from

A CASE OF INTRA-PERITONEAL RETRO-UTERINE ABSCESS.

The abscess was situated as already implied in Douglas's space, and was the size of the fist. It was treated by incision of the posterior laquear and drainage. The abscess cavity then closed. Shortly after this a round ulcer of the stomach, that till then had been unsuspected, burst, with internal hæmorrhage. The uterus had been pushed high up by the abscess above the pelvic inlet. The speaker's impression was that the tumour would prove to be an encapsuled abscess of gonorrhœal origin. The abscess was incised on November 25th. The temperature fell on the second day, and the case progressed so rapidly that the drainage was not continued after the 13th. On the 16th she was allowed to get up, but she felt faint on getting out of bed, and returned to it. On December 12th black fæces were passed, and on the following day she vomited blood. The diagnosis of ruptured uleu ventriculi was now made, and rectal feeding was begun. The patient's condition got gradually worse, and the abdomen became moderately distended. Death took place on the 30th. At the autopsy a moderate amount of

recent peritonitis was found, but extensive signs of old peritonitis, not only in the pelvis, but over the liver. The ulcer of the stomach was situated near the lesser curvature, about 2 ctm. from the pylorus, and was $3\frac{1}{2}$ by 1 ctm. in size.

A second, but old, also perforating ulcer, was situated immediately behind the pylorus, on the posterior wall of the duodenum. The pelvic inlet was so much covered in by adhesions of the sigmoid flexure to the posterior pelvic walls, that the genital organs were not visible until the adhesions were separated and the sigmoid flexure drawn aside. No trace of the ovaries could be seen. The incision wound in the posterior vaginal arch had contracted, the abscess cavity was quite obliterated, and no trace of pus was present. The lesion in the pelvis was therefore quite independent of the fatal one of the upper part of the digestive track.

At the meeting of the Medical Society of the 15th ult., Hr. Hausemann showed an interesting specimen of

MULTIPLE INTESTINAL DIVERTICULA.

The preparation was taken from a man, æt. 85, who died of pneumonia. There was no history of intestinal catarrh or indeed intestinal trouble of any kind. At the autopsy also there was no indication of intestinal catarrh, or other morbid changes. The intestines were, however, occupied by a large number of diverticula, varying in size from an oat corn to a pigeon's egg. There were from 3 to 400 of these diverticula, some in the duodenum, but most of them in the jejunum, in the ileum they were less numerous. There were none in the vermiform appendix, but they were present in the ascending colon, in the descending the number increased, the number being greatest in the sigmoid flexure. In the small intestine they were mostly situated on each side of the mesenteric attachment. The interesting feature about them was that a certain relationship could be recognised between them and the blood vessels, i.e., the smaller vessels either ran over the diverticula or passed into the mesentery in their immediate vicinity. On examination small vessels were seen running into the diverticula, and this was so constant that they could always be felt with the sound. When a sound was passed along a vessel it passed into a diverticulum. It could be seen microscopically that where the small veins passed through the muscular coat a weak spot presented, a *locus minoris resistentiæ*, which became hollowed out at the spot where the vessel passed through the serous coat. This condition was most frequently met with in the aged.

Hr. Peiser showed a

TUMOUR OF THE TONSIL,

taken from a girl of 15, in Baginsky's Poliklinik. The girl's mother stated that the child had suffered from remarkable attacks, every time it coughed it got no air, and it had the feeling as if something flew in from the throat. Examination soon explained the riddle. As soon as the tongue was depressed, a small tumour was seen attached to the tonsil by a short pedicle. There were also hypertrophy of the tonsils and rhinopharyngitis. It was clear that during inspiration the tumour was drawn in, and gave rise to the sensation described. The tumour was readily removed, when all the symptoms subsided. No microscopic examination of the growth had yet been made, but it was almost certainly a fibroma papillari verrucosum, as in the case described by Luschka and diagnosed by Waldeyer.

Austria

[FROM OUR OWN CORRESPONDENT.]

Vienna, Feb. 1st, 1896.

SYPHILITIC SOLEBROSIS FROM A BITE.

PROF. NEUMANN showed a patient to the "Gesellschaft" with a typical sclerosis on the hand and pronounced enlargement of the glands situated immediately above the elbow, some of which were as large as hazel nuts. The hardening followed a bite from an antagonist in a scuffle about fifteen months ago, and was rapidly succeeded by a syphilitic exanthem, papules in the mouth, and on the tonsils, for which he attended the clinic as an outdoor patient.

PEOSPERMOSIS CUTANEA VEGETANS.

He presented another case, to which he said it was difficult to assign the correct nomenclature. Dernier, at the Dermatological Congress, 1881, excited considerable discussion on a similar case which he designated on that occasion *peospermosis follicularis vegetans*. The disease appears on the skin in the form of a universal eruption of nodules, apparently in the follicles of the skin, and not unlike small papular syphilides, or favus.

From these symptoms and carefully prepared sections of the skin, Dernier was led to the conclusion that the changes are of a paraeitic nature, and that the *peospermia* phenomena are nothing else than a degeneration of the epithelial cells.

Neumann said the female shown was *set.* 17, who had always enjoyed good health. Two or three years ago circular eruptions appeared on the neck, breast, abdomen, more particularly in the axillary and inguinal regions, of a greyish brown colour, and with a good deal of thickening. Interspersed among these forms could be found fine pointed nodules, of a dark colour, from which, when scratched, a horny layer might be lifted off. In some places they appeared like condylomata, in others as molluscoid growths. This eruption was pretty general over the entire body, but more abundant over the sternal region, between the shoulders, on the lateral regions of the thorax, and the dorsa of the feet.

It is now evident, from the clinical and pathological examinations, that this disease may be grouped among the hypertrophied cutaneous maladies with implication of the cutis, epidermis, and their adnexa, bearing a close relationship to hyperkeratosis, of which ichthyosis is an example.

RUPTURE OF THE BICEPS.

Baum showed a case of ruptured biceps in a carpenter. The man had worked for many weeks after the accident, the injury having been overlooked by his medical attendant, who treated the patient for a contusion. The patient was 55 years of age, and he had had both bones of the forearm broken a year ago. This was treated with gypsum bandages, &c., and union took place. On the 25th of November, 1895, he was raising a block of timber with rope and pulley when the timber suddenly slipped, coming in violent contact with his arm, which seemingly tore the muscle. When viewed anteriorly, a swelling about the size of an apple could be observed lying in the middle line of the forearm, with a deep furrow above. On searching for the biceps, the internal portion could be discovered *in situ*, while the external was retracted far up the arm.

The typical subjective symptom seems to have been present in this case, viz., the feeling of sharp pain, as if the injured part had been heavily struck with a cane.

He was able to raise the forearm when it was pronated, but unable when supinated, corresponding with partial rupture of the muscle.

According to Maydl's statistics, we find that out of a total number of 103 ruptures, 17 occurred in the biceps, 5 of which were total, 6 partial, and the remainder undetermined.

HYPERTROPHY OF THE PROSTATE AND CASTRATION.

Schnitzler showed the Society a case where he had removed both testes with perfect success in the curing of an hypertrophied prostate. Before the operation the patient was unable to urinate voluntarily, but on the following day passed urine easily, and he has not since the operation required a catheter.

The Operating Theatres.

KING'S COLLEGE HOSPITAL.

TWO CASES OF DISPLACED SEMI-LUNAR CARTILAGE.—Mr. ROSE operated on a young soldier who, four years previously, had displaced his internal semi-lunar cartilage whilst wrestling. It became reduced spontaneously, but, owing to the limb not having been immobilised, he suffered frequent recurrences, which incapacitated him from his military duties. The joint was at that time opened by Mr. ROSE, and the internal semi-lunar cartilage, which was found loose, was stitched into position along the border of the tibia. The man made a good recovery and returned to duty. Eight months ago he twisted his knee, and the displacement recurred. He was invalided home, and admitted to King's College Hospital for further treatment. The joint was again opened by a transverse incision along the line of the old cicatrix, and the dissection carefully carried down to expose the periphery of the cartilage, which was found contracted, displaced, and shortened. It was evidently no longer possible to stitch it into position, so the ring was divided and the two ends were drawn apart and stitched to the periosteum over the head of the tibia in such a way as to prevent them from slipping back between the ends of the bones. The joint was carefully closed, and the limb immobilised on a splint.

The second case was that of a schoolmaster, who more than a year ago displaced his external semi-lunar cartilage at football. By manipulating his knee he reduced the displacement, but owing to the constant recurrence of the accident he sought surgical advice, and was admitted to hospital. The joint was opened in the same way as in the previous case, but on the outer side, the ilio-tibial band being, of necessity, partially divided. The margin of the cartilage was defined, and found to be so loosely connected and so much damaged by a kind of splitting process, that it was thought advisable to excise nearly the whole of the outer two-thirds, a proceeding of some difficulty as regards the posterior portion. In this case a temporary drain-tube was left in the joint for twenty-four hours. Mr. ROSE remarked that he had now operated on several similar cases, and with the most gratifying results, and he looked upon the performance of the operation as a most convincing proof of the immense advantages of antiseptics, without which such a proceeding would be unjustifiable. He laid stress on the perfect quiet and the position of the limb, namely, an elevation at an angle of about 40 degrees, which should be maintained for about ten days after the operation.

It is satisfactory to state that both cases are progressing favourably.

MIDDLESEX HOSPITAL.

NEPHRO-LITHOTOMY.—Mr. BLAND SUTTON operated upon a man, *æt.* 45, who had for the past fifteen years suffered from pain in his left side extending to the pelvis. At first these pains used to come on at an interval of a few months, but for the last two years he was scarcely ever free from them, and on at least two occasions he passed a small fragment of calculus. There was no clear history at any time of hæmaturia. His bladder was carefully sounded but no stone detected. The left renal region was very tender to pressure, and was fuller than usual. The urine contained slight traces of pus. The usual incision was made in the left ilio-coastal space and the kidney carefully freed from its capsule and drawn into the wound but no stone was found in its substance. On feeling the pelvis of the kidney a number of stones were detected. An incision was then made in the convex (posterior) border of the organ; the finger passed through into the pelvis and seventeen calculi were extracted; two were equal in size to a shelled walnut and the remainder were as big as peas. The pelvis was dilated but the renal cortex was of normal texture and the kidney itself was far above the average size. The incision in the renal cortex was closed with three catgut sutures, the divided muscles of the back reunited with buried catgut sutures, and the skin brought together by means of silk; a large drainage-tube was introduced and the wound dressed in the usual manner. Mr. Bland Sutton remarked that there was very little doubt in regard to the diagnosis of the case but from its long history he expected to find considerable disorganisation of the kidney such as extensive hydro- or pyo-nephrosis and it was surprising, he thought, considering the large number of stones, to find the kidney not only healthy but abnormally large. This may be explained, he said, in two ways: 1st, the calculi in the pelvis were as loose as marbles in a schoolboy's pocket, so that the urine could filter between them and make its way unobstructed to the ureter, had one of these stones obstructed the ureter rapid hydro or pyo-nephrosis would have been the immediate consequence; 2nd, the unusual size of the kidney made the surgeon apprehensive that its fellow had been destroyed by disease, and that this was the only renal organ that the patient had to depend upon, and this would cause the operator a certain amount of anxiety in the subsequent course of the case.

It is stated by the *Broad Arrow* that in the event of the required number of candidates not being forthcoming at the next examination for appointment in the Army Medical Service, it is the intention of the authorities to re-appoint those gratuitised medical officers with the rank of Surgeon-Major on the retired list liable to be recalled to service. This decision will affect about seven or eight officers, and the information will doubtless be received with great satisfaction by them.

It is stated that in New Orleans, about £200,000 is annually spent for milk. Since one-third of this milk is reported to be composed of water from the mains, the citizens of New Orleans are obviously paying upwards of £80,000 for the water contained in their milk.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 5, 1896.

IS COLLES' LAW ABSOLUTE?

THE discovery by Colles' fifty years ago, of the so-called law which bears his name, was justly looked upon as a highly important addition to our clinical knowledge of syphilis. Its interest is not merely scientific or even clinical, indeed, as will be seen, it opens up on every hand questions of the greatest practical importance both from the point of view of daily practice as from that of the possibility of acquiring immunity therefrom. If it be really the case that the healthy mother of a congenitally syphilitic child can never contract the disease from her offspring, it shows that some influence has been brought to bear in virtue of which she has become possessed of a certain immunity against an otherwise extremely infectious disease. For half-a-century this "law" has served as a guide to practitioners in authorising such mothers to suckle their offspring. The advantages to the offspring are obvious and the risk to the mother nil, always assuming that the rule is absolute. Every-thing turns upon the question whether the law is or is not one admitting of exceptions because if it could be proved that, though rare, infection did occasionally take place, practitioners would necessarily become more circumspect in the matter of giving the requisite assurance against possible contamination on the part

of the mother. Syphilis is such a terrible disease and exerts such far-reaching consequences that no conscientious practitioner would consent to run any tangible amount of risk in the direction of infecting a hitherto previously healthy mother. Dr. George Ogilvie initiated what proved to be a very interesting discussion at the last meeting of the Royal Medical and Chirurgical Society by a paper in which he sought to prove that exceptions to Colles' law, if rare, were by no means unknown, and he quoted in support of his contention two *inter alia* of a number of clinical observations, the painstaking accuracy of which apparently left nothing to be desired in spite of the fact that the problem is one which presents peculiar difficulties in respect of the admissibility of the various items of evidence. Mr. Hutchinson, who is a firm believer in the law in question, naturally took up the cudgels in defence thereof, but he rather gave his case away to begin with by declaring that a law is usually proved by its exceptions, and to this rule Colles' law, according to him, was no exception; in other words, while, for all practical purposes, it was a rule of sufficiently general application, like other rules, it admitted of exceptions. Then, too, there is the possibility that some apparent exceptions may really be second attacks of the disease. The rule that one attack of syphilis renders immune against future attacks is one which has received the sanction of experience, but this same experience shows that the immunity is relative rather than absolute. The proportion of alleged exceptions to Colles' law does not appear to be greater than that of second attacks of syphilis, and viewed from this point of view the risk might perhaps be considered as *quantite negligible*. However this may be, Colles' law is, with many, a dogma which is now blindly accepted, and which it is regarded as rank heresy to question, ignoring the cardinal principle that in considering such complicated and obscure problems as those furnished by medicine and pathology, everything of the nature of dogmas ought to be avoided in order not to place unnecessary barriers in the path of subsequent progress. We are all the more indebted to those who, like Dr. Ogilvie, take the trouble to point out the weak points in the laws laid down for our guidance, even though, after full discussion, one comes to the conclusion that he has not succeeded in impugning its clinical value. Incidentally, a very interesting point was raised with regard to the frequency of infection of wet nurses by congenitally syphilitic children. Colles described this form of syphilis as virulently infectious to all except the mother of the child, and it might be inferred from his remarks that it was an exceedingly exceptional occurrence for a wet nurse under these conditions to escape contagion. That, however, is certainly not the experience of the present day, for cases of the kind are extremely rare, so rare as to be almost unknown. Mr. Hutchinson adroitly sought to claim the credit for this rarity for Colles' law, which, by calling attention to the liability to infection of nurses other than the mother, made it incumbent on medical men to protest against any woman

being exposed to the danger. This suggestion, however, will not hold water, because we know pertinently that it is a very common practice among the lower classes of society for women to nurse each others' children more or less indiscriminately, without any infection of the nature under discussion. The rarity of infection among hired or volunteer wet nurses, even in giving the breast to syphilitic children, *pro tanto* weakens the force of Colles' law, because, obviously, the non-infection of nursing mothers might be attributable to the same cause as that of the strange nurse. If the mother of a syphilitic child be immune against infection by her own offspring she must *pari passu* be protected against contamination of that kind from any source, a point too often overlooked in discussing this subject and one, too, respecting which direct evidence appears to be wanting. As bearing on the rarity of infection of nurses other than the mothers of these children it is worth noting that according to those who have opportunities of observing many cases of congenitally syphilitic children, mouth lesions are very uncommon, so infrequent indeed as to be something of the nature of a curiosity. It can hardly be supposed that a child who does not present lesions of the mouth will infect his nurse, whether mother or stranger, and this affords us an explanation of the immunity of nurses which applies with equal force to the mother as to the wet nurse. In acquired syphilis, on the other hand, mouth lesions are the rule instead of being the exception, and this may enable us to understand why acquired syphilis has the reputation of being vastly more infectious than the hereditary form of the disease.

THE NEW PHOTOGRAPHY.

PROFESSOR RÖNTGEN'S recent announcement that certain rays have the power of penetrating substances commonly regarded as opaque, continues to attract world-wide discussion. His discovery has roused the earnest attention of all students of physical science, who are busily investigating the nature of these peculiar rays. He has created no little stir in the medical world, where it is hoped that the practical application of his new rays to "the new photography" may ultimately have an important bearing on the diagnosis of deep-seated conditions in the human body. Then he has plunged the scientific photographers of many countries into a state of feverish excitement, as they speculate and experiment upon the new wonder thus offered to their already marvellous craft. Lastly, his scientific "find" has furnished an endless supply of material for the general newspapers and their readers. Indeed, it is simply astonishing with what rapidity the news of Professor Röntgen's discovery has traversed the whole civilised world and roused the universal interest of all sorts and conditions of men. Another hardly less striking fact is the number of scientific men who are to be found in every country ready and competent to investigate the newly-described phenomena. It is reported that German men of science have taken up the task with enthusiasm, and, among other things, are searching for some means of shortening the long exposure at present

needed to produce the new photograph. Some success has already been attained in that direction, for one experimenter has found that by heating the photographic plate to about 40° Centigrade, the process occupied only fifteen instead of thirty minutes. In England, it is gratifying to note, photographers have not been behindhand, some having been engaged for many months past in the self-same pursuit, as is testified by an advanced copy of the *Royal Photographic Society's Journal*, with which we have been favoured. The issue in question contains several interesting papers dealing with the subject, in addition to a valuable series of photographs illustrating the capabilities of the new process. One of these, which was taken by Mr. J. W. Gifford with an exposure of ten minutes only, we have reproduced on another page, it being the most perfect anatomical specimen of a living hand we have as yet seen. From the published papers of Professor Röntgen, it appears that he himself does not feel inclined to classify his new rays among those of the ultra-violet spectrum. He has, however, suggested the following hypothesis:—"A kind of relationship between the new rays and light rays appears to exist, at least, the formation of shadowy fluorescence and the production of chemical action point in this direction. Now, it has been known for a long time that besides the transverse vibrations, which account for the phenomena of light, it is possible that longitudinal vibrations should exist in the ether, and, according to the view of some physicists, must exist. It is granted that their existence has not yet been made clear, and their properties are not experimentally demonstrated. Should not the new rays be ascribed to longitudinal waves in the ether?" An answer to this question will doubtless be speedily forthcoming. Professor Goldstein, of the Royal Observatory at Berlin, in a recent lecture pointed out that the fact that Röntgen's rays are not deflected by magnets does not prove that they are new, since there are certain cathode rays which are likewise uninfluenced by magnets. The main characters of Röntgen's rays are shared by several other kinds of rays. According to Goldstein, the common characteristics of cathode rays and the new rays are rectilinear propagation, the production of shadow photographs, and chemical action. The species of rays to which Röntgen's belong cannot yet, he thinks, be determined, but there are many grounds for believing that they belong to the cathode species. Whatever be the outcome of further investigations into the new phenomenon, it seems certain that one more marvel has been added to the treasure-house of modern science, and one that bids fair to bring forth abundant fruit in due season.

THE ELECTION TO THE GENERAL MEDICAL COUNCIL OF A DIRECT REPRESENTATIVE FOR IRELAND.

By the advertisement which appears in our columns to-day, the contest for the vacant position enters upon its final stage. It is intimated that nomination papers,

formally signed and executed, must be sent to the Branch Registrar, Dr. Wilson, on or before the 15th inst., it being provided that the candidate must be a registered medical practitioner, and that he shall be nominated by at least twelve registered practitioners resident in Ireland. These details are, in themselves, interesting. It will be seen that the candidate must be a registered medical practitioner, which is an essential requirement *only* in the case of a Direct Representative. A representative of a university, or college, or a Crown nominee, under the authority of the Medical Act of 1858, may be any "person" whomsoever, male or female, medical, clerical, or legal, the apparent reason of this anomaly being that several of the representatives of universities are elected by Convocation, a body which contains a majority of non-medical members who, it is quite possible, might please to elect to the Medical Council some distinguished educationalist who had never qualified in medicine. It is not, however, essential that a candidate shall be resident in Ireland, though his nominators must be so, and it would be competent for any twelve registered practitioners living in Ireland to nominate an army surgeon who is on duty in India and, if such nominee gave his consent to the nomination, his name would go to the poll for the Direct Representation of Ireland. This is, of course, a reduction of the system to an absurdity, but it is worthy of notice as an illustration of the vagaries of the law.

Since we last wrote on the subject, the situation has become more defined. The Cork Local Association has issued voting cards, as we stated that they would, to every voter, for the purpose of ascertaining which of the three provincial candidates (naming Dr. Cuming, Greene, and MacDonnell, and excluding Dr. Jacob and Thomson) is likely to score the highest poll, it being guaranteed that the two unsuccessful candidates shall retire in favour of the candidate who received the greatest amount of support. It is thus worth while to speculate as to who is most likely to come out successfully in this preliminary "canter," and a list of his "Committee," issued a couple of days since by Dr. MacDonnell, affords us opportunity for doing so. His total following, so far as this list divulges it, is 168 voters. Dr. Cuming's following, as set out in his original list, numbered 343, and no one but Dr. Greene himself knows what his following is, inasmuch as he has issued no list. Looking at these figures by themselves, and recollecting that Professor Cuming has, no doubt, gathered in some adherents since he issued his list, it seems most probable that he will head the preliminary poll, and that Dr. MacDonnell and Dr. Greene will retire. But, on the other hand, it should be recollected that almost the whole of Dr. Cuming's supporters are from Belfast and the neighbouring Northern counties, and that his list showed only 35 supporters from the whole of Ireland outside that locality. It also seems most likely that on this preliminary vote Dr. MacDonnell will score many more votes than Professor Cuming, inasmuch as the Professor is essentially a Belfast School and College spokesman, and neither has, moreover, had anything in common

with the working country practitioner, while Dr. Mac-Donnell, though he never served at the plough as a Poor-law Medical Officer, can claim that he has had some limited experience in such affairs. It does not, however, appear that the voters think very highly of such claim, seeing that within the past month he has only succeeded in accumulating fifty-eight votes, of which the largest number came from the very unenthusiastic compact of the Carlow-Kilkenny Society to vote together. In the event it seems most probable that our forecast will be fulfilled—that the contest will lie between Drs. Jacob and Thomson, with Professor Cuming striving in a useless effort, the only effect of which will be to withdraw votes from both these competitors.

As a further contribution to the consideration of this contest we publish, in our Irish Supplement of this day, a strongly expressed and forcible address by forty Workhouse and Dispensary Medical Officers, representing a much larger number of Dr. Jacob's supporters in these services, in which the Poor-law Medical Officers of Ireland are appealed to not to allow personal considerations to prevent them from giving that gentleman their vote. Dr. Jacob also, in a separate address, points out that voters who may have promised their support to one or other of the plebiscite candidates, will be entirely absolved from such promise if the candidate to whom it was given retires, and that it will, in such case, be quite open to them to transfer their votes, not to the candidate who may come out first in the plebiscite, but to him whom they may think best fitted to represent their interests. We shall not do more than recommend those who are interested to read the appeal of the Poor-law Medical Officers which appears in our Supplement of this day.

Notes on Current Topics.

Consanguineous Marriages in Relation to Disease.

THERE is ample evidence to show that consanguineous marriages play an important role in the causation of disease, and that hereditary diseases are much augmented by such marriages. Among other observers the testimony of Dr. Berniss is somewhat noteworthy upon this point. He gives an account of 833 marriages between relations, in which he finds the following results: In ten cases of incest with parents, or between brother and sister, 93 per cent. of the offspring were defective. In twelve marriages with niece or aunt 75 per cent. were defective. In fifty-six marriages between blood relations, the issue of blood relations, 53 per cent. were defective. In twenty-seven marriages between double first cousins 27 per cent. were defective. In 112 marriages between second-cousins, 13 per cent. were defective, while in 125 marriages between persons in no way related, only 2 per cent. were defective. But while these facts clearly display the evils of the intermarriage of blood relations in the human species, confirmatory evidence, as is well known,

also exists upon the same subject among the lower animals. The close breeding-in of animals has long been known to affect deleteriously the qualities of the offspring. Darwin has, for example, remarked that, "with respect to pigs, there is more unanimity among breeders on the evil effects of close inter-breeding than, perhaps, in regard to any other large animal." This same observer also relates that a well-known breeder bred a family of pigs in-and in for seven generations; the number of pigs was reduced at each gestation, and of the offspring thus produced many were idiotic, without sense even to suck, and when attempting to move could not walk straight, until finally one sow was the sole offspring; she would not become pregnant by her sire, while to a stranger in blood she bred at the first trial. Among the diseases most commonly associated with consanguineous marriages is that of retinitis pigmentosa, and there does not appear to be any doubt that the intermarriage of blood relations largely conduces to the causation of this curious affection. In ninety-five cases reported by Liebreich, in which the parentage was traced, forty-three were of consanguineous origin, or 45 per cent., and throughout the domain of ophthalmological literature repeated references may be found to the same effect, that is to say, confirmatory of the causal relationship between consanguineous marriages and retinitis pigmentosa. The whole subject under discussion is discussed in a paper published in a recent number of the *Medical News*, late of Philadelphia, now of New York, by Dr. Oliver Belt, of Washington. The conclusion arrived at by the author is that as there are few families entirely free from constitutional defects of some kind, "a prudent person would do well to avoid a consanguineous marriage in any case, not necessarily on account of deafness, but on account of the danger of weakening the constitution of the offspring." With regard to deaf-mutism, statistics show, for the most part, that the closer the degree of relationship between the parents the more numerous are the number of the deaf-mute children born. For example, one marriage between an aunt and nephew produced three deaf mutes. Four marriages between uncle and niece produced eleven deaf-mutes. Twenty-six marriages between first cousins produced thirty-eight deaf-mutes. Sixteen marriages between second cousins produced twenty-eight deaf-mutes. Forty-seven marriages between blood-relatives produced seventy-two deaf-mutes. These are important facts which leave no measure of doubt as to the influence of the intermarriage of blood relations in causing the deaf-mutism. But just in the same way as consanguineous marriages should be avoided, so also should the intermarriage of persons tainted with hereditary disease be discouraged. Heredity is a most potent factor in the matter of "Visiting the sins of the fathers upon the children," by means of which many tainted and diseased offspring are brought forth, and too much care, strictly speaking, cannot be exercised in this connection, despite the powerful incentive to overrule all considerations which sentiment at the time may create.

A Curious Prosecution under the Medical Acts.

THE magistrate at Marlborough Street Police Court had a curious case before him last week. A person named Albert Bell, of 175 Wardour Street, Oxford Street, was summoned, under the Medical Acts, for using the letters "M.D.," and the title of "doctor" without being a duly qualified medical practitioner. On the defendant's name being called there was no answer. In stentorian notes, resounding throughout the court, the defendant was summoned to reply to his name, but without avail. At last, when all the officials had made themselves quite hoarse with shouting, the magistrate, in order to create a diversion, asked "Is the defendant here?" The solicitor for the defence said, "No, sir, he has been dead for several years." This was accepted by the court as a satisfactory explanation for his non-appearance, but in order that the play might proceed in an orderly manner, it was necessary to find another "Hamlet." As it happened this was no great difficulty. A person named "Henry Walters" obligingly, at a moment's notice, took up the part, and then the curtain was raised, and the serio-comedy proceeded without further incident to its termination. It appeared that Henry Walters, some years ago, bought the business of the late Mr. Bell, which had for long been carried on under the name of "Dr. Bell." Henry Walters was, therefore, sailing under false colours by allowing "Dr. Bell's" name to remain on the door of the premises. However, it was admitted that Henry Walters did not prescribe physic for those who came to consult him. His mode of practice was of an innocent, simple description, suitably adapted for innocent, simple people. The Court was informed that he recommended all his patients to use a belt which would cure anything and everything in a month. But the magistrate seemed to think that Nature never intended that sick persons should be "cured" in so simple a manner as this, and accordingly Henry Walters was fined £20, with six guineas costs, with the alternative, in default of distress, of two months' imprisonment. The "piece" was so well received by the audience that they were provoked to frequent bursts of laughter. Upon the whole, therefore, from every point of view, this little serio-comedy could be pronounced a distinct success.

Medical Men and Dr. Jameson's Raid.

MORE than one medical man has had to submit to arrest at the hands of the Boers in connection with the disturbance at Johannesburg, and the son of the Medical Officer of Health of Swansea has now found himself in this predicament. Dr. Davies is one of the Council of the Uitlanders, a matter of some moment, inasmuch as the latest accounts from Johannesburg state that the Council has accepted the whole of the responsibility for Dr. Jameson's raid. This, undeniably, is a serious position for the members of the Council to have assumed, and if this information be correct, the Boers have still the prime leaders of the disturbance against them in their safe keeping, despite the fact that they have released the Chartered Company's men. The whole of this business is a sad one, and not least, by

reason of the fact that a member of our own profession, who had won for himself the admiration and respect of all who knew the great work that he had accomplished, is now on his way home to stand his trial for having committed a serious breach of International law, and by so doing, for the present, if not for ever, arrested the course of what promised to be a great career.

The Appointment of Director-General of the Army Medical Department.

OUR contemporary, the *United Service Gazette*, hits the right nail on the head when, in discussing the appointment of the Director-General of the Army Medical Department, it urges that the tenure of this office should be limited to five years, instead of seven, as is the case under the present régime, and that extension, by a year at most, should only be granted under the most exceptional circumstances. The prizes in the Army Medical Staff are all too few, and slowness of promotion is not only a cause of universal complaint but of wide discontent in the Department. But this is only one of the reasons which can legitimately be urged in favour of the reform suggested. Under the circumstances, however, with the approaching retirement, early in May, of the Director-General of the Department, the opportunity is admittedly a good one for the War Office to fully and carefully take into consideration the need which exists for revising the regulation for the tenure of this important post. Such a reform is one which might well be taken in hand by the new Commander-in-Chief, for the expediency of it cannot but appeal to a practical-minded authority like himself.

Medical Men in Nottingham and the Medical Aid Associations.

IN common with their *confrères* in other parts, we are glad to see that the medical men of Nottingham have taken a firm stand against the system of so-called medical aid associations. We have repeatedly referred to this matter in our columns, and pointed out the derogatory character of the appointments associated with these nothing more nor less than trade concerns. It is satisfactory, then, to note that at a crowded meeting of the medical men of Nottingham held last week the following emphatic resolution was passed: "That in the opinion of this meeting it is unprofessional and undignified for any medical man to accept the post of medical officer of any institution promoted by, and for the pecuniary benefit of, men outside the profession." There is no doubt that if medical men throughout the country would only take a firm stand on this question and loyally support each other, the medical aid associations, as at present conducted, would soon cease to exist. Everything, however, has been done, short of compulsion, to bring those practitioners to reason who have so far identified themselves with the promoters of these associations, and the time would seem to have arrived when the matter should again be brought under the notice of the General Medical Council. Had the

Council only had wisdom enough to see that its duty was to condemn the connection of members of the profession with these unprofessional appointments, the difficulty would soon have been settled. But such wisdom was not to be found in the academic minds of the majority of the members of the Council, and consequently, owing to this absence of a firm policy, the medical aid associations have ever since flourished amazingly, to the serious and lasting detriment of the hard-working members of the profession.

The Physiology of the Carbo-hydrates.

THE appearance of a short paper by Dr. Noel Paton in the February number of the *Edinburgh Medical Journal* on the above subject in reply to a book by Dr. Pavy entitled an "Epicriticism," merits a word of comment. Dr. Paton, about a year ago, criticised Dr. Pavy's previous book on the same subject in a somewhat trenchant manner. This criticism touched Dr. Pavy on so sensitive a point—his great and only theory of a sugar-destroying liver—that he must needs publish, not a paper but a book in reply. To us his book is everything that such a reply should not be. It is personal when it should deal with facts, it imputes unworthy motives on ridiculous grounds, and it drags in quite unnecessarily a private quarrel with the officials of the Royal Society into what purports to be a scientific refutation of a brother physiologist's erroneous ideas of an important subject. Dr. Pavy complains that Dr. Paton takes him at a disadvantage in quoting so many authorities against his views, confessing at the same time that he is not in the habit of consulting the work of others if he can help it. Dr. Paton's present reply shows that he has no thought of retiring from his opinions as previously expressed, and he adds further testimony against Dr. Pavy's theory, testimony which Dr. Pavy will find it very hard to refute. It is amusing to find that Dr. Paton is more than ever convinced of the improbability of the truth of Pavy's hypothesis after reading the "Epicriticism," which it was confidently stated would demolish his position entirely. As in another recent controversy the honours of the first round rest with the combatant who has taken up an impersonal position.

The Population of France.

OFFICIAL statistics of the standing of the population in France for the past year have just been published, and have given rise to a considerable amount of disappointment among political economists—the figures are as follows:—Births, 855,388, showing a decrease of over 19,000 on the previous year; deaths, 814,620, or a decrease of 52,000 as compared with the previous year. From which it results that the births have decreased by 23 per cent., and the deaths, 6 per cent. Consequently, the apparent increase of the population is entirely due to a decrease in the mortality. The number (76,451) of illegitimate births is excessively high, showing a constant increase during the last ten years. The number of marriages was 286,662, a decrease of 632 on the preceding year, while the divorces are put down at 6,419.

A Novel Method of Raising Funds for Charities.

AN altogether novel departure in the cause of charity has been devised by the management of the National Hospital for the Paralysed and Epileptic (Albany Memorial), Queen's Square, Bloomsbury. It is proposed, in the words of the prospectus submitted to us, to return to donors "unable to sacrifice present income, but desirous to benefit the charity," annuities calculated at from 4 to 5½ per cent. upon the amount of the gift. Any sum from £50 upwards will be received upon these terms, and a gift of £1,000 will be considered to provide for the future endowment of a bed, upon which the donor may at once bestow a distinctive name. The scheme provides absolute security for the payment of the annuities, and may be commended to the charitable as a sound and practical means of perpetuating and extending the usefulness of an institution truly national in its scope. Instead of themselves receiving the annuity, donors may nominate some other person as the recipient, and in this way provision may be made for dependents and others during their lives, with an ultimate reversion of a substantial sum to the hospital. Full information will be afforded by the Director at the hospital.

Culpable Neglect of the Public Safety.

DIPHTHERIA has of late become one of the most fatal and widespread of zymotic diseases, a fact which has been generally attributed to the facilities for spreading the disease afforded by the congregation of children in Board Schools. It is a difficult disease to control, a fact which is in a great measure accounted for by the confusion of diagnosis in many cases between ordinary sore-throat and mild or early diphtheria. In a London police-court a week since a peculiarly callous case of reckless exposure to diphtheria infection was brought to light. The defendant's child was notified to be suffering from the disease, and the house was visited by a sanitary inspector. Seventeen days later, however, he transferred the infected house and business to another person, whom he did not inform of the existence of the disease. He was summoned by the St. Pancras Vestry for having failed to have his house disinfected. We are glad to see that the magistrate imposed a fine of £5, and two guineas cost, for what he called "a culpable negligence in regard to the public safety."

Burning of a Small-pox Hospital.

THE inhabitants of a place called Oakridge, near Stroud, are evidently a practical-minded race. Against their will a small-pox hospital had been erected in their midst, but had not yet been opened. Thereupon, the good people of the district held a kind of witenagemote, and in spite of the opposition of a handful of local police, proceeded to burn down the offending hospital. The newspapers report that the ringleaders of the mob are now lodged in Gloucester Gaol, where they will doubtless have leisure for reflection upon the foolishness of taking the law into their own hands. The case illustrates in an extreme manner the deep-rooted objection most people entertain against "fever" hospi-

tals, that is to say, in their own neighbourhood. Many of the mob who destroyed the Oakridge institution would no doubt, if stricken with small-pox, gladly avail themselves of a similar shelter in someone else's district. So long as infectious diseases exist it will be necessary for the authorities to provide special isolation hospitals. Of course, no man would willingly have a small-pox hospital built next door to his dwelling house, but for all that the fact remains that in a crowded neighbourhood a secluded site is not to be procured at any cost. Fortunately, modern investigation has proved that infection round small-pox hospitals is almost invariably conveyed by personal agencies, while the theory of aerial spread is altogether exploded.

Bravery of a Medical Man.

THE late disastrous explosion at Tylorstown, South Wales, was the occasion of much courageous rescue work. Among other noteworthy incidents of the kind, we are pleased to chronicle the bravery of Dr. Thomas Morris, the Medical Officer of the collieries where the disaster occurred. As soon as the state of the gearing permitted the descent of the rescue party, the doctor went down and spent the whole day underground, where he did much service among the injured survivors. In the afternoon he was summoned to a wounded man who lay a mile and a quarter along one of the workings. To reach him the doctor had to scramble and struggle as best he could through many parts of the wrecked workings. The injured man was unconscious, and was kept alive by artificial respiration, conducted at intervals on the wearisome and dangerous journey back to the pit's mouth. The workmen of the district at a local meeting passed a resolution thanking Dr. Morris for the noble efforts he had made in the work of exploration, and in saving the life of the collier Phillips. This kind of heroism is less conspicuous but not a whit the less sterling than deeds of derring-do upon the battle-field.

Suicide in Germany.

A CURIOUS series of statistics, collected from the different States of the Empire, has just been published in Berlin, showing the number of suicides which have been committed in Germany during the thirteen years from 1881 to 1893 inclusive. According to this return the number of suicides for that period was 105,327, the totals ranging from 8,987 in 1881, to 10,699 in 1893, and that rate per head of the population varied very much being as high as 46 per 100,000 inhabitants in the Duchy of Saxealtenburgh, and falling as low as 13 and 11½ per 100,000 inhabitants in Bavaria and Alsace-Lorraine. The suicides are proportionately more numerous in the Prussian Army than in any part of the Empire, having been 65 per 100,000, in 1893.

OUR French correspondent writes us that considerable commotion has arisen in one of the small towns in consequence of a woman having just given birth to a female child with two heads. The latest accounts reported that the monstrosity had every intention of living.

Measles and the Notification Act.

THE St. Pancras Vestry recently had under consideration the question of making measles a notifiable disease under the Notification Act. The matter was ultimately referred to the Medical Officer of Health for the parish, and his report has just been issued. Among other things, he states that at least 3,000 beds would have to be specially reserved for measles cases in London, even if only fifty per cent. of the cases were sent to the hospitals. He adds, moreover, that "the inevitable conclusion is that in large towns the value of the notification of measles is small unless accompanied by provision for hospital accommodation and disinfection." In view of this report the Vestry decided to proceed no further with the suggestion above referred to.

Alcohol and Fever.

SHOULD fever patients be given alcohol? This was the question discussed last week at the annual general meeting of the governors of Chester Infirmary, over which the Duke of Westminster presided. His Grace directed attention to the expenditure for wines and spirits, narrating his experiences as chairman of a hospital, and suggesting that, while in cases where necessary patients should not be deprived of wine and spirits, yet it required watching. Mr. Taylor, honorary surgeon at the infirmary, said that it was true that the expenditure on stimulants had increased, but that was due to the gravity of the fever cases treated in the institution. Such patients had required more stimulants; and Dr. King added that better results had been shown in the treatment of fever cases by the use of a certain amount of alcohol. The governors of medical charities should always place confidence in the medical staffs of the institutions with respect to the administration of alcohol. No hard and fast rule can be drawn in the matter. Some epidemics are more serious in the effects than others, and, consequently, the patients do better stimulated by alcohol and *vice versa*.

The Cigarette and its Disadvantages.

THE American Laryngological Association at a recent meeting had a long discussion upon the subject of cigarette smoking, and in a paper read at the meeting Dr. Mulhall, of St. Louis, although a smoker of cigarettes for twenty-five years, makes some pertinent observations upon the evils of the habit. The only active toxic agent present in a cigarette is nicotine, and this may cause harm or not according to a variety of circumstances. The chief element concerned, when without exception it is productive of harm, is youth. General experience shows that every child who smokes tobacco habitually suffers serious impairment of health. In adolescence, and practically this may be said to be from puberty until eighteen in females, and twenty-one in males, the evil is not so great, but is still a great one, for, although the nervous crisis of puberty has been passed, the nervous system is still rapidly developing. The nerves, after puberty, are more resistant than in childhood, but, on the other hand, greater demands are

correspondingly made upon them, either by the higher phases of education on the one hand, or by the actual daily struggle for existence on the other. It seems to be indisputable that the use of tobacco is a serious handicap in the progress of youths. Investigations so far seem to show that the percentage of winners in intellectual and athletic contests is considerably higher among the total abstainers from tobacco. In the condemnations which Dr. Mulhall reiterates in regard to the cigarette most medical men will agree. The seductiveness of the cigarette is its mildness, by which repeated small doses of nicotine are absorbed and cause their toxic effects upon the nervous system. In consequence of its mildness, too, the cigarette is fast coming into favour with ladies, by whom neither pipe nor cigar smoking could be tolerated without direful results.

The Royal College of Physicians, London.

The ordinary quarterly *comitia* of the Royal College of Physicians, London, was held on the 30th ult. when the following gentlemen were admitted as Members of the College:—Bertram L. Abrahams, M.B.Lond.; Cuthbert C. Gibbee, M.D.Aber.; Albert S. F. Grünbaum, M.A., M.B.Cantab.; John S. Stanley, M.D.Edin.; and Seymour G. Toller, M.D.Lond. With becoming loyalty the Fellows passed a resolution of sympathy with the Queen and Princess Beatrice, upon the death of Prince Henry of Battenberg. Since the last *comitia* a memorial tablet has been placed in the library. It bears the following inscription:—

"In remembrance of Sir Henry Halford, Bart., G.C.H., M.D., F.R.S., for 24 years president of the Royal College of Physicians; to whom mainly is owing the removal of the college from the City to this site; to whose personal influence with King George IV. was due the grant from the Crown of the ground on which this edifice stands; and who on June 25th, 1825, opened it, with an elegant Latin oration, in presence of an audience the most distinguished that has ever assembled within the walls of the college. To perpetuate the memory of these services, and of Sir Henry Halford's untiring efforts to maintain the culture, character, and position of the English physician, and the welfare and dignity of this college, and to mark the admiration and gratitude with which he was regarded by his contemporaries, this tablet, by a vote of the college, has been here placed."

The Diplomas in Public Health were granted conjointly by the Royal College of Surgeons to ten medical men, and Licences to practice Medicine, Surgery, and Midwifery, were conferred upon a large batch of gentlemen.

A Remarkable Dermoid Cyst of the Ovary.

DERMOID cysts are simply freaks of Nature, and may occur in various situations of the body, but the ovary in the female and the coccygeal and thyroid regions in the male are their favourite spots of selection. According to Paul Mundé, who records some interesting observations on the subject in the December number of the *American Journal of Obstetrics*, dermoid cysts of the ovary may remain dormant for a number of years, but they are apt, finally, to spring into activity at one of three chief periods of life, first, that of puberty, or second, that of marriage, or third, that of childbirth.

Each of these different periods seem to exert a stimulating influence upon the growth of these tumours. The author narrates the case of a virgin, æt. 41, from whom he removed a dermoid cyst of the ovary, the contents of which consisted of a tress of hair, surrounded by a small amount of a pea-soup like fluid. On dissolving the sebaceous material in ether the hair was cleansed, and subsequently it was found that the tress actually measured no less than seven feet in length. In colour it was of a dark blonde, and in structure was as perfect as that of the hair of the female head, only perhaps a trifle finer. All this mass of hair sprang from one small nipple, not more than one inch in diameter, situated upon the internal wall of the cyst. Such a unique case as this is worthy of record.

THE brother of the late Canon Liddon, Dr. Edward Liddon, J.P., of Taunton, was presented a short time ago with a testimonial by the members of the Taunton Vale Harriers, the Mastership of which he had held for twenty years. The gift consisted of a large loving cup of Georgian pattern, mounted on an ebony stand, attached to which was a silver plate, bearing the names of one hundred subscribers.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

THE MEDICAL ADVISER TO THE COMMISSIONERS OF PRISONS FOR SCOTLAND.—We understand that there are many applicants for the office just vacated by Sir Douglas MacLagan. Two medical knights, one of them Sir Henry Littlejohn, some University professors, and numerous smaller fry are eager to win £200 a year with not very much to do for it. It would be a great pity, however, if the appointment were given to anyone who already occupies posts, the proper upholding of which entails constant personal supervision. Too often posts with fixed duties go to those who have, and not to others, and quite as good men, who have not, owing to influence acquired in the performance of the duties of the other appointments.

FIRE AT THE EDINBURGH ROYAL INFIRMARY.—Early on Saturday morning last a fire occurred in the premises belonging to the Edinburgh Royal Infirmary, but occupied by the College of Physicians as a laboratory. Luckily the fire was confined to the rooms in the top flat, and the only damage done to the rest of the building was caused by water. Some of the workers in the histological department in the top flat have, however, lost much interesting and valuable material. The work of the laboratory will be carried on, in the meantime, in a detached part which entirely escaped the effects of both fire and water.

SCOTTISH POOR-LAW MEDICAL OFFICERS.—The first annual dinner of the members of the Scottish Poor-law Medical Officers' Association took place in Glasgow on the 30th January. The Chairman, Dr. Bruce, of Dingwall, in proposing the toast of the Association, said that it was nearly forty years since he was chosen Poor-law medical officer for a small Aberdeenshire parish, and not long afterwards one of his near neighbours was ousted from his office because he had asked for an increase of salary. An attempt was made by some of the medical officers to get the Board of Supervision to lay down a distinct rule refusing to sanction such a proceeding, but without success. The Board of Supervision had jurisdiction by law in the case of the inspector of poor, and it was thought the law should be extended to the medical officer. There was and is no law authorising them to claim such authority to ensure fixity of tenure. The object could be attained, however, by making the grant in aid for medical relief dependent

on the right of appeal being given to every medical officer participating in the grant. He believed that the Local Government Board did unofficially set its face against arbitrary changes of Poor-law medical officers. As to remuneration, he did not think that the officers received adequate payment in all cases; indeed, in some instances, of which he knew he was aware that the salary was too small for the work expected. He considered that it was a public duty to see that the salary was sufficient to pay for generous medical treatment. There should also be a superannuation fund; in short, the Poor-law medical officer should be put on the footing of a properly salaried independent civil servant.

Literary Notes and Gossip.

A TRANSLATION from the Swedish language of a book on "Modern Woman," which has attracted much attention on the Continent, is about to appear in English. The authoress is Mrs Hansson, wife of Prof. Hansson, a Swedish literary celebrity.

WE have received from Messrs. Cassell and Co. the first part of "Cassell's History of England" as well as of "British Battles on Land and Sea," including, with the latter, a large presentation plate. Both publications are excellent, and should command a large sale.

THE "Chemist's Compendium," by Mr. C. J. S. Thompson, is a useful little volume, carefully compiled, which chemists and pharmacy students will appreciate for the vast amount of information which it contains in a small compass. We can cordially recommend it.

AT the small price of half-a-crown Messrs. Philips & Co. publish an excellent anatomical paper model of the human head and neck, illustrated and described by Dr. Schmidt, and translated by William S. Furneaux. The model, of convenient size, is designed after the manner of Witkewski's atlases which acquired such a wide reputation.

WE understand that Dr. John S. Billings, who is no doubt known to many of our readers as editor of the *Index Medicus*, and compiler of the Index Catalogue of the Surgeon-General's Library at Washington, has been offered and has accepted the responsible and lucrative office of Librarian of the new Consolidated Libraries of New York.

AN acceptable calm seems to pervade the medico-literary atmosphere in succession to the storm of mental activity evolved in the production of new works and new editions which prevailed during the past few months. No new venture of importance has reached us during the past month, and gossip is silent as to the future in this direction.

A USEFUL little publication, "The Phonographic Outlines of Medical Terms," has just been issued by the Society of Medical Phonographers. It contains a list of outlines and contractions for about 2,500 of the more common medical terms. The list is arranged in alphabetical form, and begins with "abdomen," and ends with "zygomatic."

ACCORDING to the *Publishers' Circular*, a new book of sermons is published every day, five novels every twenty-four hours, six histories or biographies each week, two educational books every morning; art and science only get a recruit about twice a week, law once a fortnight. The grand total of new publications in 1895 was 5,581. How many of the authors of these books are now wiser and sadder persons?

WE have received the half-yearly volume, July to December, 1895, of "Braithwaite's Retrospect of Medicine." As usual, the volume is full from cover to cover of good material culled from the best medical literature throughout the world. We notice, however, some misprints in the spelling of words, chiefly in the obstetrical section, which have inadvertently escaped the notice of the Editors.

DR. BOND, of Gloucester, sends us a copy of a useful leaflet drawn up by him and entitled, "Our Duty in Regard to Vaccination, or fifteen reasons why we should believe in the efficacy of vaccination as a preventive of small-pox." This might be distributed broadcast in those districts where recalcitrant Boards of Guardians have failed to do their duty in prosecuting defaulters under the Vaccination Act. In the Bristol district also, where Mr. Walter Hadwen holds forth, some copies might be useful.

SOME papers in the *Edinburgh Medical Journal* for the current month are "Remarks on the Results of Surgical Measures in a series of Cerebral Cases," by Dr. G. A. Gibson; "Diabetes Mellitus in Early Infancy," by Dr. W. B. Bell; "Public Vaccination in Edinburgh," by Dr. W. Husband. It would be a great convenience, both to reviewer and reader, if the proprietors of this journal would follow the lead of their contemporaries, and issue the copies with the leaves cut.

The Scalpel, although a new claimant for the favour of the reading medical public, is really the *Provincial Medical Journal* under a new name. The latter journal departed its life at the end of last year, but the Editor decided to raise out of its remains another journal, to which he has given the name of *The Scalpel*. The first number of the venture is before us. It appears in an attractive cover, and its contents are similar to those with which the readers of its predecessor have made themselves familiar.

THE United Kingdom Branch of the Dufferin Fund has established four new scholarships of £50 each, tenable for two years, to be held by ladies who, having already practised in India, were desirous of obtaining the higher degrees in medicine at an English University. Two of these scholarships, the Queen-Empress and the Dufferin, have now, respectively, been awarded to Miss D. E. Pratt, Assistant Surgeon at the Lady Lyall Hospital at Agra, and Miss A. N. DeSouza of Amritsar. Both ladies were formerly students at the Calcutta Medical College.

REFERRING to the paragraph in our last month's "Literary Notes" on the piracy by American authors and publishers of English medical books, a leading New York publisher writes us, "We quite agree with you that it is time such plagiarism should be stopped, and one of the ways to do this is, to make the facts as public as possible." We would go further than this, and say that if America would consent to the same Copyright Act as exists as a matter of honour between European nations, this piracy could not take place, and authors and publishers alike would be protected.

IT would appear that New York is fast becoming the *Ultima Thule* of medical skill and thought in the United States. For example, the centralisation there of the leading professional journals is truly remarkable. The *Medical News*, above referred to, is the second medical journal, the editorial offices of which have been recently removed from Philadelphia to New York. All this would seem to show that the competition of New York as a centre of learning, enterprise, and influence is becoming too great to be withstood by the other large cities in the States.

WITH the removal of the *Philadelphia Medical News* to New York, and a change in the editorship, a notable improvement is already apparent in the Journal. The "orthographic atrophy," which under the former régime was so marked a feature of our esteemed contemporary, has now almost disappeared from its pages. Evidently the attempt to foist the new-fangled system of spelling scientific words does not find any favour with the editors of the best organs of the profession in New York. We congratulate the new Editor of the *News*, Dr. J. Riddle Goffe, upon his assumption of a policy in his charge of the Journal which cannot fail to prove acceptable.

The Practitioner for February is a good number, and fully maintains its position as one of the best of the monthly periodicals issued. The editor has, since the commencement of the new year, increased the size of his

journal to 112 pages, and has undertaken to give every month a portrait, together with a short biography of a "hero in medicine." In the number before us this honour is conferred upon Giovanni Battista Morgagni. Among the original communications Dr. W. M. Ord discourses on "Renal Diseases," Sir Thornley Stoker on "Excision of the Knee-joint for Tuberculous Disease," and Dr Charteris on "The Prevention of Sea Sickness in Short Voyages."

THE Editor of the *Australasian Medical Gazette*, Dr. Knaggs, has dedicated the use of his library in Sydney to the members of the medical profession in his district, and for three hours every afternoon his collection of books will be open to any medical practitioner who may desire to pay it a visit. The formal dedication of the library took place last month, at a meeting to which special invitations were issued by Dr. Knaggs to the Presidents, Members of Council, and officials of the New South Wales branch of the British Medical Association, the suburban medical societies and the Newcastle Medical Society. The fact that such a step as this should have been taken by a private member of the profession rather shows that Sydney must be badly off for a public medical library.

As evidence of the dishonesty to which English authors are subject, we need only mention the case of a "System of Surgery by American Authors," recently issued. On receipt of the first volume in this country, the American system of surgery was discovered to be most pronounced in its absence, and English authors had been so plagiarised that the sale was prohibited in Great Britain, and the volumes had to be promptly returned to the home of their birth. Of course, this might have been a mere coincidence, and the American Authors might not have known of the existence of the English works, but they will, perhaps, pardon our suggesting that it would have been more straightforward had they issued the work as an *American System* (not in surgery) we should have understood it here.

THE medical officers of Schools' Association has done well in calling attention, by means of a pamphlet, to an attendant evil on Rugby football in the shape of a skin disease, communicated during scrummaging work. It is known scientifically as Football Impetigo, and among schoolboys by the expressive idiom of "scrum pox." The pamphlet is the work of Mr. H. G. Armstrong, M.R.C.S., Medical Officer to Wellington College, and the author describes how the contagion is confined almost to the forwards, and it seems as though the hardest pushers are the ones most certainly affected. The only possible means of keeping down the affection, if not absolutely abolishing it, is scrupulous attention to the purification of jerseys, which should be thoroughly cleansed after each match.

DR. CONAN DOYLE, of "Sherlock Holmes" fame, has just appeared in a new rôle. A firm of large advertisers of a quack medicine have brought out a small book, in which the virtues of their commodity are set forth in all the usual blatancy of such purveyors, but as a special inducement to read the announcements, the book also contains a story by Dr. Conan Doyle, which is said to be interesting. This "literary production" is intended by the firm to reach the hands of the public through the chemists who sell their concoction. No doubt, as an example of business enterprise, this feature of advertising is quite novel. At the same time, we question very much the good taste of a medical man, even under the form of literature, having anything to do, however remotely, with the sale of a quack nostrum.

WE have received the Appendix to Dr. Neale's "Medical Digest" for the years 1891-95, and we must congratulate ourselves and the profession on the unwearying activity shown by the author in continuing to provide us with this admirable index to current medical literature. Such a work of reference is indispensable to writers on medical subjects, for without it the task of looking up previous allusions to a given subject would be beyond the powers of any individual investigator. It was, however, originally intended for the assistance of the busy practitioner who finds therein a means of ready

reference to such discoveries, new doctrines, and different modes of treatment in each department of medical science as are likely to prove of interest. For practical purposes a single reference to the "Digest" will often give all the information required without looking up the particular papers indicated. It is a stupendous work, and Dr. Neale has earned the gratitude of generations of medical practitioners as yet unborn. We see that the "Digest" may be obtained in one volume at the extremely moderate price of 18s. 6d., and on such terms it really ought to find a place in the library of every medical man.

NEW BOOKS AND NEW EDITIONS.—The following have been received for review since the publication of our last monthly list:—*International Encyclopædia of Surgery*, edited by John Ashhurst, jun., M.D., LL.D. Vol. VII. *Epidemic Ophthalmia*, by Sydney Stephenson, M.B., F.R.C.S. Ed. *The Treatment of Pulmonary Consumption*, by V. D. Harris, M.D., F.R.C.P. Lond. *The Theory and Practice of Counter-irritation*, by H. Cameron Gillies, M.D. *The Art of Compounding*, by Wilbur L. Scoville, Ph.G. *Cottage Hospitals*, by Hy. C. Burdett. *Middlesex Hospital Reports for 1894 The Causes and Treatment of Lateral Curvature of the Spine*, by R. Barwell, F.R.C.S. (Fifth Edition). *Dictionary of Treatment*, by William Whittle, M.D. (Third Edition). *Statistical Report of the Health of the Navy, 1894-5 (Blue Book)*. *Formulaire des Medications Nouvelles*, par le Dr. H. Gillet. *Deaf-Mutism, a Clinical and Pathological Study*, by J. K. Love, M.D.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

LUNATIC ASYLUMS—THE RELIGIOUS QUESTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the few remarks I offered on this delicate subject I had no idea of referring to Dr. Hyslop's views in any capricious or cavilling spirit, at the same time I may repeat that if "a true and philosophic religion" is conducive to a state of sanity, it is only fair to ask which is the true one, and for the life of me, speaking personally, I have never been able to find out. Dr. Hyslop moreover denies that cases of religious enthusiasm which culminate in insanity are greater than those which arise from alcoholic stimulants. I believe I am correct in stating that the question is an open one, because, as a matter of fact, it is next to impossible on any system extant, to arrive at a conclusion as to how many become insane through drink, because it so happens that the causes of insanity are in many respects identical with those which lead to alcoholic intemperance, and these are often operative at the same time in the same individual. For example, Dr. Hyslop has enumerated different factors in insanity amongst which I recollect overwork is one. Now, let us suppose a temperate person became insane from overwork, I apprehend lunatic experts would tabulate this as a cause of the insanity; but supposing further, another individual, in undergoing his transitional journey from a sane to an insane state, became intemperate, overwork acting as an incentive in this direction, the cause assigned in this case would, I surmise, be alcoholism, but according to the hypothesis this individual was going insane before he commenced drink, and indeed, so far from the case of insanity being the effect of drink, it would be much nearer the truth to allege it as the cause.

And here it may be premised that statistics on the point based on any numerical calculations must be fallacious, yet these are the statistics in which the extreme teetotal party, an extremely dangerous class of fondists, delight in dabbling. While on this point permit me to remark that for many years I have held the opinion that alcoholic stimulants judiciously applied may in some cases be a powerful factor in preventing insanity, and if it be asked what evidence there is in support of such a supposition, I answer that inasmuch as mental depression from any source is a factor in insanity, it is impossible to escape the conviction that moderate stimulation, of course, short of producing pathological changes in nerve structure, must

tend to counteract such depression, and hence may under varied conditions of life tend to maintain sanity. This view of mine is, no doubt, heterodox to asylum superintendents, but I am quite open to conviction on the other side; meanwhile, I would beg that our lunacy authorities should be extremely cautious in committing themselves to statements as regards drink and its relation to insanity, as agitators readily seize asylum statistics above all others to frighten the weak portion of the community from taking that which may, under some conditions, be necessary to maintain the integrity of the nervous system, and thus unintentionally be doing detriment to the public service. Thanking Dr. Hyslop for his courteous letter,

I remain, sir, yours gratefully,
Queen's Road, Peckham, CLEMENT H. SMES.
January 30, 1896.

THE NOTIFICATION CASE - HADDEN FUND.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The following is a list of subscriptions received through various sources previous to the hearing of the appeal, in addition to the list published in this journal on Jan. 22nd.

THE RECENT REMARKABLY LOW DEATH-RATE IN LONDON.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—During the fourth quarter of last year the deaths in the metropolis from all causes rose but little above an annual rate of 17.7 per 1,000 of the population, which is 2.0 below the average for the corresponding periods of the preceding ten years, being, in fact, the lowest but one on record. This is highly satisfactory to the community at large, and might afford solace to the heavily-taxed rate-payers, were it not for the other side of the picture. Those who do not question the benefit derived from improved sanitation as regards dwelling houses, open spaces, &c., are apt to grumble at the enormous expense attaching to the erection and maintenance of the ever-increasing isolation hospitals. And this complaint is shown to be not without reason, by the fact that notwithstanding the above-mentioned large diminution in the general death-rate, there was an actual increase in the zymotic death-rate of 0.5 per 1,000 living. Moreover, the deaths from notifiable diseases formed no less than 44 per cent. of the zymotic class, instead of 30 per cent., as formerly.

I am, Sir, yours, &c.,
D. BIDDLE

Kingston-on-Thames, Jan. 31, 1896.

Laboratory Notes.

HUNYADI JANOS WATERS.

It is now many years since we had occasion to notice this laxative mineral water, not inaptly termed "the natural aperient." Since that time its popularity appears to have extended on all hands until its name may be said, without exaggeration, to have become a household word. We have, on more than one occasion, referred to the curious fact, first pointed out by Sir Henry Thompson, of the indisputably greater efficacy of natural solutions of aperient salts over artificial preparations, however skillfully combined. Summary clinical and analytical tests prove that its activity and chemical composition have undergone no change, in fact, the results of the most recent investigations afford evidence of the care which, we are informed, is taken to insure uniformity of strength and therapeutical action. The advantages attending the use of natural mineral waters are, perhaps, not sufficiently appreciated in this country, but their use has greatly increased during the last decade or so, especially among the educated classes of the community, who are usually the first to avail themselves of remedial innovations. Hunyadi Janos is certainly the best known, and, in our experience, the most trustworthy of the Hungarian laxative mineral waters—the so-called "bitter-waters." Taken in the morning, either pure or diluted with hot or cold water, it produces a copious evacuation without leaving behind it any intestinal discomfort or exhaustion.

HARTMANN'S SANITARY TOWELETTES.

We have already had occasion to speak of these cleanly and convenient appliances in terms of high commendation, and inspection of the fresh batch of samples to hand justifies our repeating past expressions of satisfaction. These towelettes are made of wood-wool (a good-sucking matter, as a German firm describes it), the absorbent properties of which are well known, secured in layers of gauze. They are made in various sizes—the ordinary size at a price "which defies competition," together with larger sizes for menorrhagic females, and a specially well-padded variety for use during the puerperium. The margin of absorbability is so large that transudation is practically impossible. Anything more hygienic, cleanly, and convenient it is difficult to conceive, and they cannot fail in the long run to become a national institution.

At a quarterly meeting of the Committee of the Central London Throat, Nose, and Ear Hospital the recommendation of the Medical Committee to inaugurate a Bacteriological Department was confirmed, and Mr. St. George Reid was appointed to take charge of it for the ensuing twelve months.

Medical News.

British Medical Association—The Carlisle Meeting.

Dr. BARNES, Carlisle, the President-nominate of the British Medical Association for the current year, has received a telegram from the Canadian branch of the Association at Montreal asking Carlisle to cancel the arrangement for the holding of the annual meeting in the latter city in July, in favour of a proposal to hold it at Montreal. Dr. Barnes's reply was to the effect that the preparations for the Carlisle meeting had gone too far to permit the request to be entertained. The office-bearers for the Carlisle meeting have been appointed, and all arrangements are proceeding satisfactorily.

The Medical Guild.

THE second annual meeting of the Medical Guild was held in the Victoria Hotel, Manchester, on Thursday, Jan. 30th, 1896. Dr. Henry Simpson in the chair. The annual report of the Council stated that 62 new members had joined during the year, bringing the number to 114, and that many matters of interest to the profession had come before the Council, such as professional organization generally, rate supported fever hospitals, the improper employment of unqualified assistants, unprofessional advertising, the registration of midwives, "Provident Medical Aid," &c. The report and statement of accounts were received and adopted on the motion of the Chairman, seconded by Dr. Dixon Mann. Various alterations of the rules were discussed and agreed to. A special report has been drawn up by the Council on "Provident Medical Aid" dealing with the Friendly Societies' Sick Clubs, Provident Dispensaries and Medical Aid Associations, and suggesting methods by which the evils in connection with such organizations might be remedied. On the motion of Dr. W. Fraser, seconded by Dr. Ratcliff-Gaylard, this report was adopted and copies ordered to be sent to the medical press. The following Officers and Council were elected for the ensuing year:—Chairman, F. H. Walsley, J. P.; Vice-Chairman, J. Dixon Mann, M.D., F.R.C.P.; Hon. Treasurer, C. G. L. Skinner, M.D.; Hon. Secretary, Alexander Stewart, M.D. Council, J. Brassey Brierley, M.D.; Wm. G. Booth, G. H. Broadbent, S. Bagley, Colin Campbell, W. Fraser, M.B.; J. H. Gosdon, M.B.; C. R. O. Garrard, J. Ratcliff-Gaylard, W. Sowers Scott, M.D.; James Holmes, M.D.; T. Arthur Helme, M.D.; N. C. Haring, M.B.; R. H. Quine, F. Leyland Roe, A. Brown-Ritchie, M.B.; G. H. Pinder, S. Woodcock, M.D.; S. McNair and R. H. Wolstenholme. Auditors, E. L. Luckman and H. W. B. Montegale, M.D.

Accident to a Medical Man.

A SERIOUS accident occurred last week to Mr. F. W. Kendle, surgeon, practising at Southmolton. Mr. Kendle was driven by his groom to Bishopsclympton, and on arriving at Biah Mill the horse shied, and the occupants of the trap were thrown out. Mr. Kendle unfortunately pitched on a gate post, and received injuries which proved to be a fracture of the lower jaw, severe lacerations of the cheeks, and a severe fracture of the nose.

Vital Statistics.

THE deaths registered last week in thirty-three great towns of England and Wales corresponded to an annual rate of 19.1 per 1,000 of their aggregate population, which is estimated at 10,591,530 persons in the middle of this year. The deaths registered in each of the last four weeks in the several towns, alphabetically arranged, corresponded to the following annual rates per 1,000:—

Birkenhead 18, Birmingham 19, Blackburn 16, Bolton 22, Bradford 15, Brighton 13, Bristol 14, Burnley 21, Cardiff 12, Croydon 17, Derby 19, Dublin 27, Edinburgh 15, Glasgow 20, Gateshead 14, Halifax 17, Huddersfield 15, Hull 19, Leeds 18, Leicester 18, Liverpool 24, London 18, Manchester 22, Newcastle-on-Tyne 19, Norwich 21, Nottingham 17, Oldham 17, Plymouth 17, Portsmouth 15, Preston 17, Salford 25, Sheffield 18, Sunderland 16, Swansea 16, West Ham 14, Wolverhampton 16. The highest annual death-rates per 1,000 living, as measured by last week's mortality were:—From measles, 1.0 in

London and in Leicester, 1.8 in Birmingham, and 2.7 in Salford; from scarlet fever, 1.2 in Wolverhampton; from whooping-cough, 1.0 in West Ham and in Birkenhead, 1.2 in Portsmouth, and 2.2 in Bolton; from "fever," 1.0 in Gateshead; and from diarrhoea, 1.0 in Birkenhead. The deaths from diphtheria included 51 in London, 12 in Birmingham, 4 in Salford, 3 in West Ham, 3 in Liverpool, 3 in Burnley, and 3 in Hull.

The Mortality of Foreign Cities.

THE annual death-rate per 1,000 in the principal foreign cities according to the weekly returns communicated to the Registrar-General, is as follows:—Calcutta 41, Bombay 32, Madras 37, Paris 22, Brussels 18, Amsterdam 17, Rotterdam, 22, The Hague 16, Copenhagen 15, Stockholm 13, Christiania 14, St. Petersburg 35, Moscow 39, Hamburg 17, Dresden 18, Breslau 22, Munich 25, Vienna 23, Prague 25, Buda-Pesth 24, Trieste 24, Rome 24, Turin 22, Venice 35, Philadelphia 21, New Orleans 37.

Army Medical School, Netley.

THE following are official lists of candidates who passed the recent examinations for the Army and Indian Medical Services, and of the prizes presented by General the Right Honourable Sir Redvers H. Buller, V.C., G.C.B., K.C.M.G., Adjutant-General to the Forces, on Friday last, January 31st:

ARMY MEDICAL SERVICE.

The final positions of these gentlemen are determined by the marks gained in London added to those gained at Netley, and the combined numbers are accordingly shown in the list which follows:—

Combined Marks.		Combined Marks.	
dBrereton, F. S.	4311	Waring, A. H.	4192
Statham, J. C. B.	4438	Hooper, A. W.	4190
Cooper, R. M. C. H.	4398	Ward, W. A.	4094
Haves, E. C.	4322	Forrest, E. G.	3876
Probyn, P. J.	4274		

INDIAN MEDICAL SERVICE.

Combined Marks.		Combined Marks.	
bOchroane, A. W. R.	5139	Dawes, C. D.	4219
Clemesha, W. W.	5039	Perry, E. L.	4198
aBakha, C. R.	4994	Pinchard, M. B.	4189
Black, J. A.	4913	Niblock, W. J.	4175
Wilson, B. F.	4703	Harrison, C. F.	4173
dAndeasay, V. E. H.	4670	Hooper, E. L. F.	4098
Robertson, J. C.	4459	Lalor, N. P. O'G.	4040
Rainier, N. E. J.	4430	Symons, T. H.	4025
Kukday, K. V.	4427	Rost, E. R.	3813

a Gained the Herbert Prize of £20, the 1st Montefiore Prize of 20 guineas, the Prize in Pathology presented by Surgeon-Major-General Hooper, T.M.S., and the de Chaumont Prize in Hygiene.

b Gained the 2nd Montefiore Prize.

c Gained the Maclean Prize for Clinical and Ward Work.

d Gained the Martin Memorial Medal and the Parkes' Memorial Medal.

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAY.—King's College, 2 p.m.—Hospital for Women, 2 p.m.—Metropolitan Free, 3 p.m.—Royal London Ophthalmic, 10 a.m.—Royal Orthopedic, 2 p.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. Mark's, 3 p.m.—Chelsea Hospital for Women, 2 p.m.

TUESDAY.—Guy's, 1.30 p.m.—Cancer Hospital, Brompton, 2 p.m.—St. Mark's, 2.30 p.m.—Royal London Ophthalmic, 10 a.m.—St. Mary's, 1.30 p.m.—Royal Westminster Ophthalmic, 1.30 p.m.—Westminster, 2 p.m.—West London, 2.30 p.m.—Great Northern (Throat and Ear Dept.), 2.30 p.m.—Gordon Hospital for Fistula, 3 a.m.

WEDNESDAY.—Children's Hospital, G. Ormond St., 9.30 a.m.—Great Northern, 2 p.m.—London, 2 p.m.—Middlesex, 1 p.m.—National Orthopedic, 10 a.m.—Royal London Ophthalmic, 10 a.m.—Royal Westminster Ophthalmic, 1 p.m.—Samaritan Free Hospital for Women and Children, 2.30 p.m.—St. Bartholomew's, 1.30 p.m.—St. Peter's, 2 p.m.—St. Thomas's, 1.30 p.m.—University College, 3 p.m.

THURSDAY.—St. George's, 1 p.m.—Central London Ophthalmic, 1 p.m.—Charing Cross, 1 p.m.—Hospital for Diseases of the Throat, 2 p.m.—Hospital for Women, 2 p.m.—London, 2 p.m.—North-West London, 1.30 p.m.—Royal London Ophthalmic, 10 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—Chelsea Hospital for Women, 2 p.m.

FRIDAY.—Guy's, 1.30 p.m.—Central London Ophthalmic, 2 p.m.—East London Hospital for Children, 2 p.m.—Royal London Ophthalmic, 10 a.m.—Royal South London Ophthalmic, 2 p.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. Thomas's (Ophthalmic Department), 2 p.m.—West London, 2.30 p.m.—Great Northern (Throat and Ear Department), 2.30 p.m.

SATURDAY.—Children's Hospital, Great Ormond Street, 9.30 a.m.—King's College, 1 p.m.—Cancer Hospital, Brompton, 3 p.m.—London, 2 p.m.—Royal Free, 9 a.m. and 3 p.m.—Royal London Ophthalmic, 10 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. Bartholomew's, 1.30 p.m.—St. Thomas's, 1.30 p.m.

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ORIGINAL ARTICLES or **LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

LOCAL REPORTS AND NEWS—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

REPRINTS.—Authors of papers requiring reprints in pamphlet form after they have appeared in these columns can have them at half the usual cost, on application to the printers before type is broken up.

READING CASES.—Cloth board cases, gilt-lettered, containing twenty-six strings for holding the numbers of THE MEDICAL PRESS and CIRCULAR, may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

DR. PENDLIP (Preston).—We are disposed to doubt the veracity of the report.

PROF. GAIRDNER (Glasgow).—The article on "Glandular Therapeutics" was founded on the paper by Prof. Curatola, presented to the Obstetrical Society of London, on January 1st, a full report of which, with discussion, will be found in our issue for January 8th, present year.

MR. J. P. S.—We will have references looked up, and communicate with you further.

MR. KROHNE.—Your letter is unavoidably crowded out at press. J. V. G., asks whether the proprietor of an hotel has the right to order a sick guest to leave—assuming the illness to have occurred after arrival, and not being an infectious disease?

M. B. (London).—Such an arrangement would be contrary to precedent, and would inevitably lead to disagreeable scenes.

MR. PARKINSON (Citheron).—Your communication came to hand as we were at press, too late for consideration in this number.

ATTENDANCE ON NURSES.

A **SUBSCRIBER** asks whether it is customary to charge for attendance on nurses engaged in nursing a patient of his, and if so, ought the employer to be charged, or the nurse?

[It is usual to attend nurses gratis, but if the patient happens to be well-to-do, he would probably not object to pay for casual consultations due to the service.—Ed.]

A FASHIONABLE COMPLAINT.

DOCTOR: "You sent for me, madam; what is the nature of your complaint?"

Lady: "Ah, my dear doctor, I suffer dreadfully from—from—Whatever was the illness for which you sent my friend, Mrs. Harris, to Ostend?—*Exchange*."

Meetings of the Societies

WEDNESDAY, FEB. 5TH.

OBSTETRICAL SOCIETY OF LONDON.—8 p.m. Specimens by Dr. Playfair, Dr. Duncan, and others. Paper.—Mr. Harrison Cripps: Abdominal Hysterectomy with Intra-peritoneal Treatment of the Stump, with Notes of Eight Cases. Annual Meeting. The President (Dr. Champneys) will deliver the Annual Address.

SOCIETY OF ARTS.—8 p.m. Mr. Frederick Henry Chesswright: The Mexican Drainage Canal.

THURSDAY, FEB. 6TH.

HARVEIAN SOCIETY.—8.30 p.m. Mr. C. Mansell Moullin: Some of the Recent Results of Orchiotomy for Enlarged Prostate.

FRIDAY, FEB. 7TH.

WEST KENT MEDICO-SURGICAL SOCIETY (Royal Kent Dispensary, Greenwich Road, S.E.).—8.15 p.m. Mr. Poland will exhibit a case of Typhoid Tumour after Operation. Discussion on Cough.—Mr. Mayo Collier, Drs. Herschell, Taylor, Henry, and others.

CLINICAL SOCIETY OF LONDON.—8.30 p.m. Dr. Hale White: Two cases of Pneumothorax in the course of Typhoid Fever, and both due to straining at stool.—Mr. Pitts and Mr. Balla on: On Splenectomy for Rupture, with three successful cases.—Mr. Coiding Bird: A case of Lymph Scrofula and Lymphatic Varix.

WEST LONDON MEDICO-SURGICAL SOCIETY (West London Hospital, W.).—8.30 p.m. Mr. J. Hutchinson: The Law of Inheritance with reference to Gout.—Dr. Archibald Garrod: The *Rationals* of the accepted Treatment of Gout. Specimens of Renal Calculi will be shown by Messrs. Keetley, Edwards, Bidwell, and others.

WEDNESDAY, FEB. 12TH.

LARYNGOLOGICAL SOCIETY OF LONDON (20 Hanover Square, W.).—5 p.m. Discussion on the Nature of Laryngeal Ulcerations during the course of Typhoid Fever, to be introduced by Drs. A. A. Knathack and J. A. Drysdale.—Discussion on Foreign Bodies in the Upper Air and Food Passages, to be introduced by Mr. Charters Symonds.

Vacancies.

Birmingham and Midland Eye Hospital.—Assistant House Surgeon. Salary £50 per annum, with apartments and board. Applications to the Secretary, Church Street, Birmingham.

Bury Dispensary Hospital.—Junior House Surgeon. Salary £50 per annum, with board, residence, and attendance. Applications to the Hon. Secretary, Dispensary, Knowsley Street, Bury, Lancashire.

Cardiff Union.—Assistant Medical Officer for the Workhouse, under the direction of the Medical Officer. Salary, £100 per annum, with rations, apartments, attendance, and washing. Applications to Arthur J. Harris, Clerk, Queen's Chambers, Cardiff.

Chelsea.—Assistant Medical Officer for the Workhouse and Infirmary. Salary, £70 a year, with furnished apartments, rations, washing, coals and gas. Application forms of Wm. Miller, Clerk of the Guardians, 250, King's Road, Chelsea.

Essex County Asylum, Brentwood.—Third Assistant Medical Officer and Pathologist. Salary £120, with board, residence and washing. Applications to the Medical Superintendent.

Owens College Manchester.—Junior Demonstratorship in Physiology and Histology. Annual salary, £100. Applications to the Registrar, who will forward further information.

Staines Union.—Medical Officer, Ashford District. Salary, £50 per annum, with the usual extra fees for surgical and midwifery cases. Applications, John Anthony Engall, Clerk to the Guardians, Staines.

Walsingham Union.—Medical Officer for the No. 6 Walls District of the Union. Salary £68 10s per annum, exclusive of certain fees. Applications to the Clerk, Bridge Street, Fakenham.

Appointments

Briggs, Henry, M.B. C.M., Edin., F.R.C.S., Eng., reappointed Honorary Surgeon to the Liverpool Hospital for Women.

Brodie, C. Gordon, F.R.C.S. Eng., Assistant Surgeon to the Orthopedic Hospital, London, E.C.

Burton, J.E., L.R.C.P., Lond., M.R.C.S., L.F.P.S. Glasg., Honorary Surgeon to the Liverpool Hospital for Women.

Cameron, A.G.E., M.B., B.S., D.P.H., Camb., Assistant Medical Officer to the Small-pox Hospital Ships, Metropolitan Asylums Board.

Crawford, Raymond, H.P., M.A., M.D., Oxon., M.R.C.P., Assistant Physician to the Royal Free Hospital, London.

Davies, E. T., M.D., Edin., C.M., F.R.C.S., reappointed Honorary Assistant Medical Officer to the Liverpool Hospital for Women.

Dodgson, E. W., M.R.C.S., L.R.C.P., House Physician to St. Mary's Hospital, London.

Edis, J. B., L.R.C.P., Edin., M.R.C.S., reappointed Honorary Surgeon to the Liverpool Hospital for Women.

Fraser, P., M.D., C.M. Edin., Medical Officer of Health for the North Wales United Sanitary District.

Grimdale, T. B., M.B., Cantab., M.R.C.S., reappointed Honorary Medical Officer to the Liverpool Hospital for Women.

Miller, W. B., M.U., B.Ch. Dubl., Honorary Surgeon, West Cornwall Infirmary and Dispensary, Penzance.

Fridmore, K. L. N., M.B., Lond., L.R.C.P., M.R.C.S., Medical Officer for the Weymouth Sanitary District of the Weymouth Union.

Smart, David, M.B., B.Sc., Edin., B.Sc. Edin., reappointed Honorary Medical Officer to the Liverpool Hospital for Women.

Deaths.

BLAIR.—Jan. 30, at Fulwood, Kew, the wife of Charles Blair, M.D., M.R.C.S., of a daughter.

NEALE.—Jan. 28, at Old Bank House, Milford Haven, the wife of Albert E. Neale, M.B., B.S., of a son.

STUART.—Jan. 31, at New Elvet, Darham, the wife of Robt. Stuart, M.R.C.S., L.R.C.P. Lond., of a son.

Marriages.

EVERETT-GOODMAN.—Jan. 29, at Highbury Hill Chapel, Ernest William Everett, M.R.C.S., L.R.C.P., of Norwich, to Fanny Mabel, daughter of the Rev W. Goodman, B.A., of Highbury.

MINNS-MORTON.—Jan. 29, at All Saints' Church, Sheffield, Alan Gladys Minns, M.R.C.S., L.R.C.P. Lond., of Theford, to Gertrude, eldest daughter of Samuel Morton, M.R.C.S., of Sheffield.

ROBINSON-WILLET.—Jan. 30, at Christ Church, Westminster, Wilford Vidal Robinson, L.R.C.P. Lond., of Berstam, to Harriet, younger daughter of the late Captain John Salgren Willett, R.N.A., of Petticombe, N. Devon.

Deaths.

MARTIN.—Jan. 28th, at The Croft, London Road, Reading, Robert S. Martin, L.R.C.P. Ed., M.R.C.S. Eng., aged 81.

COGHILL.—Jan. 1st, killed in action at Krigerdorp, Kenneth Mackay Sinclair, aged 19, son of Dr. Sinclair Coghill, of Ventnor, I.W.

WOOD.—Jan. 28th, at Byng, New South Wales, Chas. K. Wood, aged 29, youngest son of the late Andrew Wood, M.D., L.L.D., of Edinburgh.

ILLINGWORTH.—Jan. 25th, from blood-poisoning, Charles R. Illingworth, M.D., D.P.H., of Upper Tooting, London, aged 41.

JACOBSON.—Jan. 21st, at 17 Allan Park, Stirling, Surgeon-Lieut.-Colonel T. W. Jackson, M.B. Glasg., B.Sc. (Pub. Health) Edin., aged 60.

KELLY.—Jan. 28th, at Park Street, Grovenor Square, London, A. B. Kelly, M.R.C.S. Eng., L.R.C.P. Edin., aged 43.

ORME.—Jan. 25th, suddenly, at his residence, The Fir, Leigh, Essex, Robert Orme, M.R.C.S., aged 56.

NOTICE—Announcements of Births, Marriages, and Deaths in the families of Subscribers to this Journal are inserted free, and need reach the publishers not later than the Monday preceding publication.

TUBERCULAR DISEASES OF THE HIP-JOINT.

By R. L. SWAN, F.R.C.S.I.,

Surgeon to Steevens' and The Orthopedic Hospitals, Dublin.

THE term "tubercular," as applied to hip and other joint diseases, was until recently a vague though intelligible designation. It was apparently originated by the writings of Nichet, "On Pott's Disease," and of Nélaton, "On Tubercular Diseases of Bone," published more than fifty years ago.

Since that time observation had demonstrated a number of facts which had enhanced the probability of a disease common in joints, being identical with a diathesis which developed local manifestations in dissimilar tissues. That disease of a similar pathognomonic type should attack in succession various joints, such as the knee, hip, spine, or bones of the carpus or tarsus. The incidence or sequence of pulmonary tuberculosis, or tubercular meningitis, during or after the existence of disease in those joints. These occurrences did not, however, advance our positive knowledge beyond that of Delpech, who, in 1816, asserted the close analogy of Pott's disease with pulmonary phthisis. He stated that tuberculosis was the only cause of that deformity which is called Pott's disease of the spine, and that, therefore, this affection should be termed "tubercular disease of the vertebrae." But it was not till the discovery of the tubercle bacillus by Koch, and its verification by Schuchardt and Krause, Bouilly, Müller, and many other observers, that a number of truths were elicited which have proved that what was so long accepted as a clinical belief had become an undoubted certainty.

Numerous cases have been recorded where wounds in individuals who were previously healthy, having become infected with tuberculosis, bone and joint diseases of the tubercular type have subsequently become developed.

Pfeiffer reports a case of a veterinary surgeon, perfectly healthy, and with a good family history, who, while dissecting a tubercular cow, accidentally wounded his left thumb. The wound healed, but induration of the scar took place. The metacarpo-phalangeal joint became swollen and presented the appearance of a tubercular synovitis. Some months later the signs of pulmonary tuberculosis supervened, and he died of the disease in 18 months after the receipt of the injury. The joint after death showed all the usual destructive changes both in the bones and synovial membrane, and a large number of tubercle bacilli were present.

Czerny records two cases where skin grafting was employed for the treatment of large ulcers, the skin having been taken from limbs recently amputated for tubercular bone disease, and those patients afterwards became the subjects of tuberculosis; one died of phthisis in 14 months, the other developed spinal disease with curvature and psoas abscess. Cases of a similar nature have been also recorded by Brandon, Peters, Middeldorpf, and others.

A youth, set. 18, was under my care in Steevens'

Hospital suffering from tubercular disease of the neck of the bladder, characterised by the usual symptoms of irritability and discharge of small quantities of sanious pus from the urethra. I sent a specimen of this to the Clinical Research Association, and received in reply—large number of tubercle bacilli present; he is now, one year after, in an advanced stage of pulmonary tuberculosis.

A proof that those strumous diseases are tubercular is also afforded by a histological examination of the affected tissues. König examined 72 specimens in the Gottingen museum, and of these 67 yielded confirmatory results. He found tubercles in bones and joints, in the walls of chronic abscesses, and in the soft tissues at the reflection of the synovial membrane, and he shows that tubercular tissue is not found in granulations of ordinary inflammation, or in acute osteomyelitis. In addition to the statements already made, that pulmonary tuberculosis is a frequent result of such disease of the larger joints, it is only when such disease is concomitant, or in immediate sequence to the joint affection, that the surgeon will recognise their pathological affinity. Many patients, however, will die at a later period from such supervention.

Cheyne states that speaking roughly 20 to 30 per cent. of the patients suffering from strumous diseases of the larger joints ultimately die of internal tuberculosis. König writes that only in 21 per cent. is the joint the sole tubercle trouble, but it is to be supposed that he includes in the larger numbers those who have implication of the neighbouring lymphatics and contiguous peri-articular tissues.

Attention may be directed to the admirable and instructive paper in the *British Medical Journal*, April, 1890, by Mr. Walter Cheyne, in which he demonstrates the possibility of induction of similar diseases in animals by the injection of tubercular material into bones and joints.

We approach, therefore, the examination of hip-joint disease on the assumption that it is the definite result of the presence of the tubercle bacillus, and that the individual so affected has not alone the local malady to endure, but is menaced with superadded and possibly fatal dangers.

It is interesting to consider at this juncture the probable method of localisation of the parasite. Allusion has already been made to accidental inoculation, and also to the experimental injection of bacilli into the tissues of animals. But in the ordinary cases of strumous joint diseases in children we must look for some other channel.

The following observations embody, I believe, the most recent opinions regarding infection and the conditions which influence it.

There are some cases of primary tuberculosis of joints, kidney, liver, spleen, &c., which appear to be associated with a foetal hæmatogenous infection (Baumgarten. Gärtner).

But in a large proportion of cases the inoculation is post-fatal—through the mucous membranes or skin.

The infection of the lymph glands is usually consecutive to tuberculosis of the skin, but Lesage and Pascal consider that tubercular polyadenitis is often congenital.

Regarding the infiltration of certain groups of lym-

phatics, it may be looked upon as due to a definite local cause. These groups may practically be named as three in number: 1st. The cervical group. 2nd. The bronchial group. 3rd. The mesenteric group.

The cervical glands are superficial and deep. The superficial lie under the platysma and receive lymphatic vessels from the external ear and side of the head and neck. The deep lie along the vessels and communicate with the tonsils, mouth, palate, pharynx, and larynx. There are also submaxillary glands which receive tributaries from the lower incisor gums, the tongue, and lower lips.

The bronchial group of glands are very numerous. They may be localised from the names applied to them, as: 1st. Intercostal. 2nd. Sternal. 3rd. Anterior mediastinal. 4th. Cardiac. 5th. Tracheal and bronchial proper.

The mesenteric group are those of the mesentery, those of the lesser omentum and the glands contiguous to the aorta. With this group the pelvic glands are sometimes, though infrequently, involved in tuberculous.

The appearance and clinical history of tubercular adenitis of the glands of the neck are so familiar to every practitioner that a short reference will suffice. There is reason to believe that they become infected from without by the entrance of bacilli through the mucous surfaces of the throat, especially when diseased through the alveoli, or from extension from tubercular disease. I have seen them consecutive to caries of the cervical vertebrae. With reference to the first method of contamination, the experiments of Cornet upon the presence of bacilli in the dusts of cities and of rooms show how widely the virus is spread, and how likely it is that in crowded centres bacilli are inhaled and even swallowed, and thus that the lymphatics are infected.

It has been suggested that, as the course of this adenitis is slower than the acute forms of disseminated tuberculous, it is due to an attenuated virus, or it becomes modified in its transmission.

Regarding the implication of the bronchial and mesenteric groups of lymphatics, we believe that the respiratory and digestive tracts admit the bacilli. But in most cases there is no definite lesion at the point of entrance. In the experiments of Klebs, who fed animals on tubercular material, he found that the presence or absence of tubercular ulcers in the intestine depended on the size of the particles. When presented in large masses, such as cheesy glands or portions of lung, ulcers resulted, but when given in minute subdivision no such lesions were found. Tubercular deposit in the bronchial or mesenteric glands are, therefore, seen in children without any mucous lesions. When we remember that the most probable cause of infection is milk from tubercular cows, an easy solution of the question of the introduction of the bacillus into the lymph channels and thence into the blood is given us. A more difficult problem is to determine the reason of the selection of a special bone or joint for the retention and development of such elements.

In addition to the well-known fact that when non-pathogenic elements are injected into the blood they are rapidly deposited in the medulla of bone, especially near an epiphysis, the developmental changes which are in continual operation in such a position in the young may favour the deposit and growth of the bacillus.

But there is, in addition, that exciting cause, in which every surgeon seems to have an instinctive belief, namely, injury, a history of which he strives to elicit. That this is a potent factor in determining the production of tubercular disease was proved by experiments on animals by Professor Krause, and also by Schüller. It was found that severe injuries, such as dislocations or fractures, were repaired readily and

not followed by tubercular disease, but that trivial injuries, such as strains or slight bruises, became tubercular. Cases are on record where fractures occurring in the shafts of bones whose extremities were tuberculous, united easily. The preceding assertions are borne out by our usual experience in hearing the history of hip-joint disease, as we find that, although there has been often some recollection of a fall or bruise, it has quite as frequently been forgotten. It has been supposed that the disturbance of the circulation in the part, similar to that of the early stages of inflammation and necessary to repair, may favour the growth of the bacillus, especially if there has been extravasation of blood laden with these organisms.

We cannot overlook that condition vaguely understood as "receptivity of the tissues." Many influences may contribute to this. While it has not yet been proved that the tubercle bacillus has been directly inherited from the progenitor (up to this, experiment is altogether against it), we all recognise the fact that the delicate offspring of delicate parents will not be likely to lead an outdoor, athletic, or healthful life, but will diminish vitality of tissue by a sedentary method of existence. That the mother may transmit the tubercular diathesis to her offspring is, however, generally admitted. The investigations of Watkins (Pan-American Medical Congress "Transactions," September, 1893) draw attention to certain granular masses in the blood termed third blood corpuscles, which occur in groups or singly, and whose function has been for long a subject of theory or conjecture. These structures are believed to be a pathological element and to declare the presence of a tubercular diathesis. This third blood corpuscle is found in pulmonary consumption; Pott's disease, hip-joint disease, chronic abscess and lupus, and tuberculous in any form is impossible without its presence in the blood.

The statement has been made by many that certain slowly-acting blood changes, called dyscrasia, precede tuberculous. Dr. Watkins believes the third blood corpuscle to be the *sine qua non* of the tubercular bacillus, and as such is one of the chief means of diagnosing this dyscrasia which it produces. In a series of experiments he claims to have demonstrated that the tubercle bacillus will live in acute tubercular blood, but will not live in blood which does not contain the third blood corpuscle.

He states that the third blood corpuscle is very often discovered in the blood of infants born of tubercular mothers, while he has never discovered it in the blood of infants born of non-tubercular women, when from the very beginning they have been nourished by their mother's breast.

The quality of the food has long been recognised as a factor in the production of strumous diseases. Watkins found that a baby in unhygienic circumstances will have the third blood corpuscles produced in its blood in from three to ten days by using sweetened milk and water, or by over sweet condensed milk.

We know that the carnivora are practically exempt from tuberculous, while the herbivora are extremely susceptible of its ravages. Man occupies an intermediate position. Bidder, in speaking of the treatment of strumous diseases, lays stress on the avoidance of substances rich in potash, and also of starchy materials, and advises the employment of albuminous foods rich in soda and fat. It is certainly true that an easy assimilation of fat appears to be unfavourable to the development of tuberculous, and persons with such a diathesis are usually averse to its consumption, and prefer the saccharine and starchy elements of food.

There is a fact which cannot fail to attract the attention of every observer, namely, the development of tubercular disease in joints after debilitating diseases. How often do we see the following: "A healthy child

gets whooping-cough, vomits constantly for weeks, becomes emaciated, partly convalesces, gets measles with some chest complaint, begins to go about, and is then found to be lame, and soon exhibits all the symptoms of tubercular morbus coxae."

If we analyse the statistics of tubercular joint diseases in the early years of life, it will be found that a practical uniformity has been arrived at by most observers as to their relative frequency. Tubercular spine disease is admittedly the most frequent, and if the aggregate of outdoor and indoor cases in hospital be taken, will far outnumber disease of any other single articulation, according to some observers, furnishing almost 50 per cent. of the whole. But if we examine the proportion of indoor cases among children, we perceive that the hip cases are fully as numerous, and I cannot avoid the conclusion that they would far exceed other joint affections in number, as hospital inmates, were it not that there is a feeling (be it correct or otherwise, I will not hazard an opinion) that the occupation of a large number of beds by cases of a necessarily slow and often uneventful progress would curtail the general usefulness of an hospital, whether regarded from the standpoint of education or philanthropy.

That diseases of the hip-joint are more frequently found in occupation of hospital beds than spine diseases may be explained by their greater exigencies. The difficulty of dealing with them efficiently in the homes of the poor. The greater suffering they occasion, and their greater liability in early life to suppuration, and its many consequences. It is remarkable how many cases of extensive involvement of the vertebral bodies may undergo retrogressive changes, or even go on to caseation, as may be seen in dissections after death from intercurrent of some other disease, and yet no abscess will happen. An explanation of this must be looked for in the mechanical conditions which inhibit movement. The extravasation of lymph round the laminae, which becomes semi-organised and serves as a posterior protective splint, and the persistent contraction of the spinal muscles in front, also to the fact that the tubercular deposit in children is usually intra-osseous, and is not so liable to suppuration, as in the case of adults where the seat of disease is most often the periphery, with involvement of the inter-vertebral fibro-cartilages. Suppuration will no doubt sometimes occur in children, and more especially if the costo-vertebral articulations be involved, and movement results as a consequence. But in hip disease the muscles not alone cause fixation, but intermittent pressure of great force from spasmodic contraction, which rapidly provokes morbid changes. This with the neglect or want of recognition of the case in the early stages, the child being often allowed or even encouraged to run about, hastens the occurrence of that most disastrous of all complications, namely, suppuration.

From thoroughly reliable extracts from the printed reports for the past five years at the Orthopaedic Hospital I have collected the following statistics.

There were in all 229 indoor cases of joint disease. Of these 88 were spinal, 85 hip-joint, 74 knees, 15 ankles, 7 elbows, but I anticipate as it has been determined to reserve special accommodation for the future for 20 hip-joint cases the results in another five years will be very different, and affections of the hip will head the list of indoor cases of joint disease.

There are different opinions as to the relative frequency of the position where disease may commence. I think it may be admitted, considering the varied opinions of different surgeons of great experience, that all situations, whether acetabular, synovial, or femoral, furnish a possible bed for a tubercular deposit.

Judging from my own experience in tubercular disease of other joints, more especially the knee and ankle, I am strongly of opinion that the primary dis-

ease is most often in the bone. Let any surgeon of extensive experience in dealing with disease of those joints, reflect how frequently when he considered the synovial structures alone engaged, and that the case was a typical one for erosion, did he find that there were indications present which made him suspect bone implication, and that even when the articular cartilage appeared healthy it was found that on making a section a caseating tuberculous mass or a sequestrum was present. I instance the knee and ankle not as furnishing any exception to a general rule, but that in those joints we have exposed to view during a formal operation those conditions which are I believe common to all articulations so affected.

(To be continued.)

Lectures

ON

THE DIAGNOSIS OF INSANITY.

By THEO. B. HYSLOP, M.D.,

Lecturer on Mental Diseases to St. Mary's Hospital Medical School,
Assistant Physician to Bethlem Royal Hospital.

LECTURE VII.

THE relationship of syphilis and insanity is a subject fraught with much difficulty, and hitherto it has provided much matter for contention. The literature of the subject is so extensive, and the conclusions of various observers so contradictory, that one may well be excused from giving vent to definite statements as to questions of diagnosis.

Certain periods in the specific histories are associated with somewhat definite types of mental disorder. Thus, during the earliest periods of infection, there may be emotional depression which sometimes passes the borderland of sanity. So-called cases of "syphilophobia" are usually characterised by states of mental depression and fear, or actual hypochondriasis. The patient is usually of a neurotic type, and may or may not have exposed himself to the risk of infection. The term "syphilophobia," when used from a symptomatological point of view, is unobjectionable, but it in no way implies that syphilis has been a factor of causation in the case.

In cases of insanity associated with actual infection by the specific virus of syphilis, there may be merely a temporary or functional derangement of the cerebral activity, exhibiting itself commonly during the secondary stages, and passing off without observable damage to the brain structures or there may be a succession of mental and somatic symptoms associated with the tertiary stages, having for its cause certain definite vascular and connective tissue changes which are, in a great measure, distinctive in their pathology. Sometimes the history of syphilitic infection is so definite, and the symptoms of syphilitic lesions are so distinct that we feel warranted in describing the cases as of syphilitic insanity. The term is convenient, and if not scientifically accurate, at least conveys to our minds a type of disease or group of symptoms which require diagnosis and special treatment. In attempting to classify the various forms of mental derangement associated with syphilis, we have two courses open to us. We may classify from the pathological or from the mental standpoint. Were the ultimate relations between the brain and mind demonstrable, doubtless a pathological classification would suffice, but ignorance of these relations, at present, hinders any such classification. It is difficult to prove that syphilis is the actual and immediate cause of insanity. The most we can say is, the syphilitic virus does induce pathological changes in the vascular and connective tissues of the

cerebro-spinal system, and these changes act mechanically by pressure or otherwise and so modify the nutrition of the nervous structures as to impair their functions. As we advance in our knowledge of cerebral pathology we may be able to demonstrate more definite associations between mental and cerebral events, in the meantime we must rest content with separate descriptions of the two series of phenomena.

Before taking account of the forms of insanity associated with demonstrable pathological changes in the cerebral tissues, I must refer to some mental states which have been included under the term "syphilitic insanity." I mean those forms occurring more especially soon after specific infection, but more generally just preceding or concomitant with the secondaries. In such cases we may have an ordinary idiopathic type of insanity, but more commonly the mental symptoms assume such forms as mania, melancholia, or alternation of these. Pure hypochondriasis is, in my experience, rare. The liability seems to depend chiefly upon (a) pre-existing disease of the brain, (b) narcotic inheritance, (c) previous attacks of insanity, &c. In most cases there is actual corporeal disease. The mere presence of a chancre, bubo, eruption, loss of hair, loss of appetite, defective nutrition, or ill-health and its sequelæ suffice to account for the melancholia, restlessness, or even excitement almost amounting to delirium. Many cases recover upon the disappearance of the bodily symptoms. In these cases the insanity would therefore appear to be dependent mainly upon constitutional effects without demonstrable pathological changes in the cerebrum.

The period at which these symptoms appear may vary from as soon as two weeks after infection to several months. As before mentioned they are most commonly met with on the appearance of the secondary symptoms, and not infrequently also disappear with them. In one case, reported by Dr. Cadell, there was great mental excitement, and restlessness almost to delirium, during the eruptive stage, and lasting nearly five months till the eruption disappeared. A year after this the hair of the head and beard fell out and the patient became melancholic, despondent, and suicidal for two years till the hair grew again which was followed by recovery. In a few cases the mental symptoms never return; more commonly, however, they reappear in a more unfavourable form with the tertiaries. The pathology of the derangement associated with the secondaries is at present hypothetical. It has been described as an irritative form of insanity due to cerebral anæmia or to the irritating effects of the syphilitic virus. In some cases gummatous products have been found in other organs while the brain was apparently healthy. For convenience I have preferred to style the mental symptoms associated with secondaries as "functional," and those demonstrably due to organic cerebral change as "organic." The organic types are divided into congenital and acquired, and the latter group is further subdivided into vascular and syphilitomatous, according to the nature of the tissue affected.

(1) Functional.

(2) Organic (a) Congenital.

(b) Acquired } Vascular.
 } Connective tissue.

It is almost impossible to define the organic types from the clinical symptoms alone for any one symptom may be stimulated by many other morbid factors. A syphilitic tumour may be simulated by an abscess, hydatid cyst, or glioma; or the hemiplegia due to thrombosis of an atheromatous cerebral artery may not differ from thrombosis due to syphilitic arteritis. We can in some cases only rely upon the history of syphilis with its succession of symptoms. By some authors, syphilis of the nervous system is said not to exist. They maintain that it does not attack the nervous substance, but that it affects the neuroglia, fibrous tissue, blood-

vessels, lymphatics, membranes, or bony coverings, involving the nerve tissue only secondarily by pressure, and so causing irritation, inflammation, and ramollissement, or by starvation from deficient blood supply, so causing degeneration and atrophy.

Congenital Syphilis.—Clifford Allbutt, writing upon mental affections in children, says, "Apart from traumatism, sunstroke, poisons, malformation, and the sequelæ of typhoid and other fevers, &c., insanity in children is practically always hereditary; though bad bringing up and excessive study may largely conspire with original tendency to produce it. If, in such a case, the parents are not actually insane, eccentric, or dissipated, we shall find that syphilitic antecedents may have been the cause of insanity in the offspring, or the father may have been well advanced in years, if not himself also of failing vigour, at the time of procreation." Drs Langdon Down, Shuttleworth, Fletcher Beach, and others, have described evidences of congenital syphilis in idiots and imbeciles. Savage believes that congenital syphilis causes death from convulsions and from other diseases in children, who would probably have been mentally defective had they lived, and that many minor nervous disorders occur in such children who are managed at home because they are physically weak, and that these lesser neuroses are seen by out-patient physicians in many patients who die before maturity.

The cases of mental defect or disorder in connection with congenital syphilis have been ably described by Savage under three heads, viz. :—(1) Those with general defect of development, with moral and intellectual want, the only feature being a distinct history of parental syphilis with evidences of the disease in the patient. Such children may have fairly well-formed heads, but, after early infancy they have not developed, they have learned to walk, but not to talk, they are restless and mischievous, and only to a very small degree educable. They require to be removed from home for the sake of the other children and for special training. (2) Those with sensory defect and consequent mental want. This group contains cases in which specific inflammation has caused deafness or blindness, or both, in early infancy; these defects leading to idiocy by deprivation of sensory stimulation. In some of these cases special education for deaf and dumb and blind fails to develop any really useful mind, and with the growth of sexual desire much serious trouble may arise, and the small mental gain effected may be ruined very rapidly. The probable end of these cases is the early death from some physical disease, such as phthisis. (3) Those with epilepsy or paralysis, and consequent epileptic or paralytic idiocy. (a) The epileptic varieties frequently begin with convulsive seizures in early infancy, and these fits recurring, become habitual and prevent mental development. In some cases the fits cease at some period of life, say about seven or fourteen years of age, but, as a rule, the mind has been too seriously damaged to recover, and the patient remains a quiet non-epileptic idiot. (b) In the paralytic cases, as also in some epileptic ones, local lesions about the cranium, the membranes, and the brain itself are the cause of the convulsive or paralytic symptoms. As a rule, these paralytic idiots are hopelessly weak, and need asylum care, and they usually live but a short time. In a few cases, the general symptoms of congenital syphilis only affect the mind later. Thus, defect of sight and hearing may act in the same way that disfigurement did in making the patient morbidly solitary, self-conscious, and suspicious; and in the end deluded and insane. These cases generally are met with in young women, and the prospect of cure is very slight, most of the patients pass into chronic weak-mindedness or delusional insanity.

There is also a fourth group, of which the symptoms may be due to inherited syphilis. These cases present

a remarkable resemblance to general paralysis. The salient features of some of them are slow but progressive dementia, with concomitant steady development of generalised paralysis and great emaciation. I have seen several cases of this type, but I am unable to say whether they are or are not true cases of early general paralysis. In adults, the syphilitic process may attack the cerebral vessels, and cause thrombosis, with the formation of a cyst and subsequent atrophy, or the gummatous material may affect the surface of the convolutions or internal nerve tracts. Possibly the same occurs in children who are congenitally affected by syphilitic disease.

The syphilitic disease may manifest itself in lesions of the bones of the cranium, the membranes, blood-vessels, brain substance, cerebral nerves, or of the organs of special sense. The skull bones may be absorbed owing to gummatous infiltrations, or small areas of caries with exfoliation may occur. The dura-mater and the pia arachnoid may be thickened and affected by various inflammatory deposits, or there may be gummata. The middle and inner coats of the arteries may show the characteristic endarteritis. Periarthritis and inflammatory deposits round the smaller arteries also occur. The brain-substance may be affected by means of an extension of the disease from the membranes, or as the result of deficiency of blood-supply. The nerve-structures of the cortex are apt to degenerate in proportion to the amount of over-growth of the neuroglia substance. The cerebral nerves and the organs of special sense may be implicated symmetrically or otherwise. The nerve fibres may become atrophied, and fail to perform their functions.

Space will not permit a full account of all the pathological data derived from innumerable investigations. I shall, therefore, merely present to you some of the more important of the clinical features for diagnostic purposes. Mr. Hutchinson believes that tertiary syphilitic symptoms are usually unsymmetrical. The diagnosis is aided by such symptoms as, palsies of cranial nerves, convulsive seizures, and hemiplegia (not the result of convulsions). Paralysis of the third nerve necessarily points to disease of the nerve trunk or of the crus close to the implantation of the nerve; a convulsion is due to discharge of some nerve centre. Too persistent hemiplegia does not follow a convulsion; such a condition is far more probably due to thrombosis of a syphilitic artery. A convulsion without details is of little use in diagnosis. The diagnosis of syphilis is not necessarily rendered invalid when anti-syphilitic treatment is unsuccessful. It must also be remembered that general convulsions do not point to the affection of any particular locality. The presence of headache, double optic neuritis, and hemiplegia would point to a lesion of one side of the brain, but, as pointed out by Hughlings-Jackson, optic neuritis alone, or convulsions alone, have little or no diagnostic value; associated, however, they are of considerable importance. Intense pain with double optic neuritis would apparently warrant the diagnosis of some foreign growth in the encephalon. This foreign growth, however, may be a glioma, syphiloma, abscess, hydatid cyst, &c., all of which produce similar symptoms. Symptoms of a gradual onset would appear to indicate a growth; whereas, a sudden onset would indicate the effects of thrombosis. Hughlings Jackson has also pointed out that double optic neuritis frequently exists when there is no evidence to show that sight is affected, and, indeed, when there is clear evidence that sight is good. Optic neuritis from syphilitic disease of the brain is regarded as in no way differing from optic neuritis the result of glioma or other foreign body. It tells us nothing more than that there is coarse organic disease of some kind within the cranium. Its diagnostic value is the same whether sight be affected or not, and there is no difference in

the optic neuritis whether the tumour or other foreign body causing it be in the cerebrum or cerebellum. It is of no value in localising beyond that it points to disease within the cranium.

There is much difference of opinion as to the part played by syphilis in the production of general paralysis. My experience in Bethlem leads me to believe that more than half the general paralytics admitted to the hospital owe their disease to syphilitic factors. Savage believes that at least 70 per cent. of his private cases of general paralysis have clear histories of constitutional syphilis. Clinically, we have to note that syphilis sometimes gives rise to a pseudo-general paralysis in which, during the early stages, the symptoms may be identical with those of general paralysis; but subsequently there is an arrest or protraction of the disease in the pseudo-form, so that the patient may live for many years. It must also be remembered that sometimes patients recover from syphilitic affections of the nervous system, but subsequently relapse and suffer from cerebral symptoms which are totally different from those of their former attack.

The epileptiform symptoms are usually suggestive of the presence of nodes formed on the internal surfaces of the skull pressing on and setting up irritation of the brain substance, or of gummatous tumours of the brain and its meninges. Typical syphilitic insanity, with its initiatory stages of cephalalgia and hypochondriasis, disturbance of the cerebral nerves, gradual loss of mental power, and of terminal dementia and paralysis, is usually indicative of meningitis affecting the cortical substance of the brain secondarily, the general result being a sort of matting together of the membranes and their adhesion to the convolutions and to the skull. The cerebral vessels become diminished in calibre, their walls are thickened by the deposition of concentric rings of plasma; as a consequence, the blood supply is diminished, and subsequently softening and apoplexy supervene.

The following considerations are compiled with the object of aiding a differential diagnosis between general paralysis and syphilitic insanity. General paralysis is comparatively rare under the age of twenty-five. Other manifestations of syphilis may render the diagnosis easy. Early paralyzes of the cranial nerves, optic neuritis, ptosis, local anæsthesias, headaches—nocturnal, deeply-seated, and increased by pressure and warmth—convulsions and local spasms, early insomnia, rheumatoid pains in extremities at night, neuralgia, local muscular spasms, vertigo, and affections of the special senses; all these may point to syphilis.

During the later stages of the disease the following symptoms aid in the formation of a diagnosis. There is usually more marked insomnia than in general paralysis, and the mental symptoms are not so commonly indicative of progressive degeneration. Physically, in syphilis there is little facial or labial tremor, although there may be hesitation of speech. The affections of speech are more paralytic than a mingled weakness and inco-ordination. Dysphagia is sudden in syphilis, gradual in general paralysis. Amaurosis, atrophy, neuritis, disseminated choroiditis, mydriasis with paralysis of muscles of accommodation more common in syphilis. Local palsies are usually independent of convulsive action. Paralyzes are local, unilateral, and affections of one or more of the cranial nerves, with hemispasm, convulsions, or anæsthesia often co-exist. In syphilis apoplecticiform seizures leave greater effects than in general paralysis. Simultaneous and unilateral paralysis of the fifth and sixth cranial nerves is suggestive of syphilis. (a)

In conclusion, I may quote the following relationships between syphilis and morbid mental states, as given by Savage:—(1) Insane dread of syphilis; (2)

(a) See Mickle on "General Paralysis."

insane dread of results of syphilis; (3) syphilitic fever, delirium, mania; (4) acute syphilis leading to mental decay; (5) syphilitic cachexia and dyscrasia, and mental disorder; (6) syphilitic neuritis (optic), with suspicion or mania; (7) syphilitic ulceration, disfigurement, and morbid self-consciousness; (8) congenital syphilis, cranial, sensory, or nerve tissue defects; (9) congenital syphilis, with epilepsy or idiocy; (10) infantile syphilis may be acquired; (11) constitutional syphilis (a) vascular or fibrous, (b) epilepsy, (c) hemiplegia, (d) local palsies, (e) general paralysis, cerebral, spinal (spastic and tabetic), peripheral; (12) locomotor ataxy (a) with insane crisis, (b) with insane interpretation of the ordinary symptoms.

Paris Clinical Lectures.

THE USE OF HOT WATER IN SURGERY.

Delivered at the Pitié Hospital,

By Dr. PAUL RECLUS,

Professor Agrégé at the Medical Faculty of Paris; Surgeon to the Paris Hospitals.

It would take too long to deal exhaustively with the various applications of hot water in the alleviation of pain, in inflammation, &c. I shall, therefore, confine myself in this lecture to the use of hot water in sprains, prostatitis, and inflammation of the internal female genital organs, that is to say, perimetrio-salpingitis.

I have, on previous occasions, described my treatment of sprains, which, however, still appears not to be generally known, although more rapid and complete recovery is obtained by my method than by the usual treatment, which, as is well known, consists of massage, wrapping the affected joint in a rubber band, or prolonged bathing with cold water. I have combined these three measures, with decided benefit to the patient, which is evidenced by the fact that I have had upwards of thirty serious cases of sprain, where recovery was obtained by this means within from four days to a fortnight.

It is unnecessary to describe the manner of applying the massage or the elastic band, as this is a very simple matter; as, however, this band is the principal thing in the treatment, it is kept on until recovery is obtained. Morning and evening, however, it is removed and the hot-water treatment resorted to. For this purpose, the sprained joint is plunged in a bath, the temperature of which is gradually raised from 48° to 50° or 52°, and even 55° C., which I consider high enough. Under the influence of this heat, the pain ceases immediately in a most remarkable manner. The circulation, and perhaps also the nutritive faculty, becomes more active, and to this fact doubtless a large share of the more rapid absorption of the peri-articular effusion must be attributed.

In addition to hot water I also use massage, which, like the elastic bandage, favours absorption of the effusion. The bandage has the advantage over massage in that its action is continuous, but it cannot dislodge clots. This is accomplished by energetic "kneading" with the fingers, which dissipates the peri-articular infiltration, thus preparing the way for the elastic bandage. My treatment of sprain, therefore, consists in the use of water at a temperature of 55° C., massage, and the application of an elastic bandage. Unless the lesion is exceptionally severe, recovery will be obtained by this means within a fortnight.

The manner in which I treat extensive traumatism of limbs by conservative methods I have recently described before the French Congress of Surgery. Whatever the extent or gravity of the lesions, I never, under any circumstances, amputate the injured limb, but merely wrap it in antiseptic substances by a veritable "embalming" process, leaving Nature to separate the dead from the living tissues. This method of treatment possesses the double advantage of being much less fatal than surgical procedure, and of preserving for the use of the patient, if not the entire limb, at any rate, a much larger part than would be left after amputation.

I should not have the courage, however, to advocate this uncompromisingly conservative treatment, were it not for the excellent effects of hot water, which I use freely in the following manner:—The patient, who is almost invariably in a state of collapse from the shock, is placed on the operating table, where he is wrapped in hot blankets, only the crushed limb being left exposed. The skin of the latter is shaved, all fatty substances are removed by the aid of ether, alcohol, or potassium permanganate, and when this preliminary disinfection has been thoroughly done, the injured parts are carefully cleansed.

The principal agent employed for this purpose is hot water from a cistern, placed at a sufficient height above the bed to insure a forcible jet. The temperature of the water should be between 60° and 62° C, but not higher, for, if it should reach 64° C, the heat would be sufficient to alter the albuminoid constituents of the tissues. This jet of hot water is made to irrigate all the injured surfaces, and to penetrate into all the hollows of the wound. This is the only way of removing all clots, and washing away foreign bodies, together with the micro-organisms they may contain.

The advantages of this application of hot water are threefold. In the first place, at this high temperature it is antiseptic. Not only it removes such germs as may have entered the wound from contact with the clothing or ground, but it also neutralises their effect. At 62° C. the development of microbes is checked. Miquel has shown that, when one cubic centimetre of liquid was maintained for fifteen minutes at a temperature of 55° C., the number of bacilli contained therein fell from 3,500 to 33. Moreover, I mix with the water a small quantity of an antiseptic, the potency of which is greatly increased by heat. Further hot water is hæmostatic, oozing is arrested, and the smaller veins and arterioles contract. But water of a higher temperature than 60° C. helps to compensate for the loss of heat, resulting from the bleeding and especially from the traumatic shock. The dangerous hypothermia gradually gives way, and in the majority of cases under my observation I have found that, when the patient left the operating table, his temperature had already risen to normal, instead of being sub-normal, as is the rule after an amputation has been performed for the purpose of remedying the effects of a traumatism. I need hardly insist upon the improvement in the prognosis under such conditions. When this irrigation has been accomplished, it only remains to have recourse to the process of embalming before referred to.

For many years I have observed the effect of irrigations with hot water in hæmorrhoids, and have invariably found it excellent. I have published numerous cases of timid patients who could not make up their minds to submit to an operation, but contented themselves at each fresh attack with the application to the anal region of gauze compresses dipped in water at 55° C. As, however, the water rapidly loses its heat, it is necessary to dip the compresses in hot water at intervals of a minute and apply them immediately to the cleft of the nates.

In addition to this treatment, the patient must every morning have an injection at the same temperature,

observing the rules which I shall lay down later on, in describing my treatment of perimetrio-salpingitis. Better results are obtained from these measures in small hæmorrhoids of recent formation, without marked contraction of the sphincter or a perceptible varicose edge. Under such conditions, the hot water treatment has invariably, in my experience, resulted in lengthening the intervals between the attacks to such an extent as to render the improvement equivalent to a cure. In severe cases, however, with large, prolapsed hæmorrhoids, and contraction and pain of the sphincter, the treatment must be dilatation and extirpation with the knife, followed by the application of catgut sutures to the mucous membrane and skin.

Hot water is particularly efficacious in acute prostatitis. I have already published several articles, and have furnished the data for several theses, on this subject, although cases of this affection are comparatively rare. The method of treatment is very simple. The cannula of an irrigator, filled with water at a temperature of from 55° to 60° C. is introduced into the anus slowly and carefully, in order not to injure the enlarged prostate which projects into the rectum. Thereupon the tap is opened very little, so as to permit the liquid to gradually escape and bathe the prostate. This treatment is repeated twice a day until complete recovery is obtained. There is almost immediate improvement, and in none of the nine cases under my observation has suppuration supervened, whatever the cause of the prostatitis and the size of the inflamed organ may have been. I have extended it to cases of congestion, which is of such frequent occurrence in hypertrophy of the prostate, and I have often successfully combated with a hot enema the paroxysms of retention of urine which, in prostatic patients, follow the slightest excess, fatigue, or chill. It is possible that the regular use of such enemata might render castration unnecessary in some cases, in which surgeons nowadays somewhat too readily resort.

The time is now past when apparently well-informed surgeons proposed and practised extirpation of the adnexa for the relief of pain on pressure in the vaginal cul-de-sac, ill-defined infiltration of the region, menstrual troubles, and a sensation of weight in the lumbar region. More than this is now required to justify laparotomy. For my own part, I never operate in the presence of these affections of the true pelvis, before I have had recourse to medical treatment in which hot water enemata constitute the principal factor. The results obtained in this way are so satisfactory that, in my wards at the Pitié Hospital, we only operate on the average on one out of three patients admitted for undoubted oöphoro-salpingitis.

Following the example of many of my colleagues, I begin by disinfecting the vagina and uterus, followed by dilatation of the cervix and prolonged drainage of the uterus, packing, and, if necessary, curetting the uterine cavity, the walls of which I treat repeatedly with topical applications, such as tincture of iodine, creosote, and graduated solutions of zinc chloride. These manœuvres have been so often described, that there is no necessity for repeating the description, except in so far as my method differs from that of other surgeons. Though it is not unusual to employ hot water, this water is not, as a rule, hot enough, the temperature ordinarily being from 40° to 45° C. whereas I use water of at least 50°, and still more frequently 55° C. The principal difference, however, is that, while other surgeons have recourse to vaginal irrigations, I employ enemata for this purpose.

Not that I entirely disapprove vaginal injections, their utility in cleansing the vagina cannot be disputed; but it must be remembered that this is about all the benefit to be derived therefrom, and these have little, if any, modifying effect on congestion of the uterus and its appendages. Their use rests on an anatomical error, for, if it is desired to reach the uterus, ovaries, and

oviducts, the operation must be carried out through the rectum. An enema results in the accumulation of hot water in the ampulla of the rectum, into which the internal genital organs project. Enemata must, therefore, be resorted to under these conditions, when they are best administered in the morning, about half-an-hour before rising. The irrigator, filled with water at a minimum temperature of 55° C., is placed on the night-table, the cannula is introduced above the sphincter, and the tap is slowly opened, so that only a small quantity of liquid passes into the intestine, the slowness of the process preventing contraction of the muscular coat. In this manner, therefore, a much larger quantity of water can be introduced than if a strong jet be turned on at once. Should, nevertheless, a desire to defæcate manifest itself, the water is shut off until this desire has passed, after which the tap is again slowly opened. The patient should retain the enema for half-an-hour if possible. Then she is allowed to evacuate the liquid, repeating the operation the next morning.

By this antiseptic treatment, drainage of the uterus, and hot enemata, I have succeeded in relieving, and even curing, a large number of cases of perimetrio-salpingitis. The infiltration of the cul-de-sac disappears, the peristaltic movements of the intestine break down the adhesions, and, instead of large masses filling up the true pelvis, the exudations and purulent collections are absorbed, the vaginal cul-de-sac become supple, the uterus movable, and the region in question resumes almost its normal condition, especially after judicious and moderate application of massage. I have on many occasions seen the tumour entirely disappear, and this result was in a large measure attributable to the use of hot water, which, as I have shown, is of the greatest value in surgery.

Transactions of Societies.

OBSTETRICAL SOCIETY OF LONDON.

MEETING HELD WEDNESDAY, FEB. 6TH.

The President, Dr. CHAMPNEYS, in the Chair.

CASE OF RUPTURED TUBAL GESTATION.

DR. PLAYFAIR exhibited a case of ruptured tubular foetation of unusual interest. The lady from whom it was taken, æt. 31, had had a child five years ago. She menstruated when travelling in Italy from October 12th to 16th. She missed her November period altogether, and believed herself to be pregnant. Early in December she started from Naples to travel to England. On reaching Milan she was laid up with very alarming uterine hæmorrhage, and thought she had miscarried. Two days afterwards the hæmorrhage had ceased, but there was an intensely offensive vaginal discharge, so marked that the odour was apparent to everyone who came into the room in which she was. In this condition she travelled home, not feeling particularly ill. This was apparent from the fact that on the day after she reached London she went to Brighton and returned the same day. Next morning, December 22nd, she felt feverish and ill, and was seen by Dr. Hollings, and the same afternoon by Dr. Playfair. The temperature was then 103°, pulse 120°, but there was no marked pain. *Per vaginam*—The uterus was fixed, there was some deposit in Douglas pouch and in the right broad ligament, but no definite tumour. These symptoms did not suggest extra-uterine foetation, the existence of which was not suspected, and the case was believed to be one of pelvic-peritonitis, following the long journey immediately after miscarriage. Next morning at 10 a.m. when in bed the patient was seized with sudden severe abdominal pain and collapse, and was believed to be moribund. The existence of ruptured tubular foetation was now diagnosed, and laparotomy was performed at 2 p.m. On opening the peritoneal cavity, the right tube was found to be dilated and ruptured, the whole outer portion having been torn off, and the posterior half, about the size of half a goose's egg, alone being left.

The remainder, and the ovum, were not found. This then was doubtless the cause of her collapse, which was so severe, that it was doubtful if the patient would be got alive off the table. The peculiarity of the case, however, lay in the fact of the blood extravasated into her peritoneal cavity, which was black and evidently old, being intensely fetid. How had the blood become thus infected, surely a very unusual occurrence? It was found that the distal extremity of the tube was patulous. Through this blood had probably escaped before rupture had occurred, and this probably caused the deposit felt on examination, and this must have been infected through the agency of a decomposing clot retained in utero, which caused the offensive discharge previously noted. The amount of extravasated blood, however, could not have been very excessive, since the patient had been able to travel from Italy. The temperature noted on the day before the operation was not due to pelvic-peritonitis as at first supposed, but to septicæmia, as was evidenced by a severe attack of pleuro pneumonia which occurred two days after the operation. The convalescence was protracted, and three weeks after the operation the wound, which had united after the removal of the drainage tube on the third day, re-opened spontaneously, and there was a considerable discharge of intensely fetid sanious fluid and blood-clot. The temperature immediately fell to normal. A drainage tube was now re-introduced, and in a week all discharge had ceased, and the patient rapidly convalesced. This combination of rupture of a tubular foetation, with septic infection of previously extravasated blood lying free in the peritoneal cavity, is apparently unique. The symptoms clearly pointed in the first instance to abortion, and were not at all those characteristic of extra-uterine foetation. It seems possible, although, of course, this is only an hypothesis, that the hæmorrhage in Milan was due to a co-existent uterine gestation, which had aborted, and from which came the retained blood-clot which caused septic infection.

EXTRA-UTERINE GESTATION.

DR. DUNCAN showed a specimen removed before rupture from a woman, æt. 30. She had twins in 1892, and from that time she was regular until October 10th, last. Between the latter date and the first of December she had no loss of blood but complained of pelvic pain. On December 1st, she was seized with acute abdominal pain though she did not faint. Four days later she had a loss. A tumour could be felt to the right of the pelvis *per vaginam* pushing the uterus to the left. The tumour was elastic and in view of the history one had no difficulty in arriving at the diagnosis of extra-uterine gestation. He operated and came down upon a swelling the size of an orange in the outer part of the left right Fallopian tube, apparently just on the point of rupture. The left tube was distended by a hydrosalpinx, so this also was removed.

DOUBLE TUBO-OVARIAN CYST.

DR. DUNCAN also showed two tumours, removed from a woman, æt. 25, who, though married, had never been pregnant. She was well until two years ago, when the abdomen began to become prominent, especially on the left side. At about that time she began to complain of pain in the abdomen and back. She consulted a doctor, who told her it was an ovarian tumour, but as she experienced no particular inconvenience matters were allowed to run on until January 6th of this year, when she applied at the Middlesex Hospital for the pain and swelling of the abdomen. He found a cystic swelling reaching up to within two fingers' breadth of the umbilicus. *Per vaginam* Douglas's pouch was found to be filled by a cyst which pushed the uterus forwards and upwards. He diagnosed ovarian tumour, and on opening the abdomen he came down upon a tumour with very large vessels resembling the gravid uterus at about the fifth month of pregnancy. This he removed along with a smaller tumour from the other side. The patient made a good recovery. The interest of the case lay in the co-existence of the two cysts, a somewhat rare occurrence.

THREE CASES OF EXTRA-UTERINE GESTATION.

DR. GALABIN showed specimens from three cases of ectopic gestation. The first was one of intra-ligamentous gestation removing after retention within the abdomen for 21 years. The patient was seen at Guy's Hospital in

1872 by Drs. Braxton Hicks and Phillips, giving a history of pregnancy going on to full term, but not terminating in delivery. The condition was diagnosed, but it was not thought desirable to interfere, and operative interference was subsequently also disadvised at the Soho Hospital. She did not experience much inconvenience until 20 years later, when the abdomen began to enlarge very much with signs pointing to an ovarian cyst. He operated and found an ovarian cyst on the right side, which he removed, and then he turned his attention to the other tumour. This was so calcified that it turned the edge of the knife. He thought it might be a calcified fibroma, and removed it *en bloc*. The patient made an uninterrupted recovery. The second specimen was one of early tubal pregnancy which had ruptured at about six weeks. There was no history of prolonged sterility in this case. She had only been married a year, and had miscarried five months after with a two months' foetus. Her last period was on October 29th. On September 3rd, she being then only five days over her time, she had a slight show, and was treated for threatened abortion. The symptoms subsided for a time, but on December 13th she was seized with violent abdominal pain, and the attack recurred with violence when she got out of bed on the 15th. She then became collapsed. She was diagnosed to be suffering from rupture of an extra-uterine pregnancy, and he saw her in the evening. The uterus seemed small, and nothing could be felt. There was nothing in Douglas's pouch, although the abdomen was slightly distended. Under an anæsthetic a small lump could be made out on the left side. He operated, and found a large quantity of dark blood in the peritoneal cavity without any clots, and in washing this away a small foetus escaped. She made a good recovery. The last specimen appeared to be a case of extra-uterine foetation, not primarily tubal, and probably ovarian. The patient, æt. 27, had had three children, the last eleven months previously, and she had been nursing this infant up to the date of the rupture. Menstruation had been absent during lactation up to last November, but in that and the following months she had normal periods. On January 14th she experienced sudden violent pain in the abdomen and fainted. She was admitted to Guy's Hospital on the 16th, and was operated upon at once. The abdomen was full of clots and fluid blood, and the gestation sac was found on the right side. This was ligatured and removed with the right tube and the upper part of the right broad ligament. There was left a large bleeding surface running across the broad ligament, which proved to be a hæmatoma which had ruptured into the peritoneal cavity. During the operation the patient became so collapsed that saline fluid was injected, and the whole pelvis was packed with iodoform gauze. She came round for a time, but died of collapse twelve hours later, in spite of a further intra-venous injection. *Post-mortem*.—Douglas's pouch was seen to be obliterated. Both Fallopian tubes appeared to be intact. A ten weeks' embryo was washed out of the cavity, this being extra-peritoneal.

DR. A. ROUTH pointed out that the last specimen was of peculiar interest, and he suggested that it should be referred to a committee for examination. It looked as if the extravasation of blood and the adventitious cyst were in Douglas's pouch.

MR. ALBAN DORAN observed that until they could meet with an ovary containing in its interior a very small and very early ovum, the existence of primary ovarian pregnancy must remain somewhat uncertain.

MR. HARRISON CRIPPS on a case of

ABDOMINAL HYSTERECTOMY WITH INTRA-PERITONEAL TREATMENT OF THE STUMP, WITH NOTES OF EIGHT CASES.

The author opined that the surgical removal of fibroid tumours of the uterus was called for in the following class of cases:—1. Excessive hæmorrhage, uncontrolled by the ordinary methods of treatment, and in which oophorectomy was impossible. 2. Serious pressure-effects on the bladder or rectum. 3. When the pain or the size of the tumour rendered the patient unable to earn her living. He contrasted the extra-peritoneal with the intra-peritoneal method of treatment of the pedicle, stating that the latter had given him the best results. Whilst in the extra-peritoneal method the danger from sepsis was slighter, that from obstruction of the intestine and ureters seemed greater than in the intra-peritoneal method. This greater

riak of peritonitis in the intra-peritoneal method was from infection through the vagina. To minimise this risk the author laid stress on two points: 1. Thorough and repeated douching of the vagina with perchloride of mercury. 2. The accurate closure of the peritoneum over the surface of the stump. He described the method of operation employed, stress being laid on two points: (a) The importance of having sufficient room, supplied if necessary by making a long abdominal incision. (b) The method of securing the vessels in the broad ligaments. This depended on whether the layers of this ligament had been separated by lateral burrowing of the tumour or not. He read notes of eight cases operated on by the intra-peritoneal method up to September, 1895. Seven cases ended in recovery, and there was one death from sepsis, due to infection from the vagina.

ANNUAL MEETING.—PRESIDENTIAL ADDRESS.

The PRESIDENT then delivered the usual address. He reviewed the negotiations which had taken place between the Society and the General Medical Council, and discussed the modifications that had been conceded in the certificate awarded to candidate midwives who had been successful in the examination held by the Society. He said that while the representatives of the Society had shown themselves perfectly ready to agree to every suggestion affecting matters of detail they had steadfastly declined to sacrifice any questions of principle. He alluded in sarcastic terms to the action of certain persons who had "twisted the tail of the Council," and remarked with some complacency that the result had possibly been quite different to that anticipated by those who had fostered the outcry, in that the modified certificate had now received the formal *imprimatur* of the General Medical Council, which was not previously the case, so that the examination was at present on a firmer footing than it had ever before been. He protested *en passant* against the spirit of trade unionism in such a matter, adding that such a spirit could not possibly be endorsed by Parliament, and if persisted in, must infallibly bring an honourable profession into discredit. He mentioned incidentally that the number of successful candidates for the certificate of proficiency in midwifery had steadily gone on increasing, that for last year being 467, as compared with 432 in 1894, a total far in excess of any previous record.

The meeting terminated with the usual vote of thanks to the retiring officers.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

MEETING HELD FRIDAY, JAN. 17TH, 1896.

The President, DR. T. W. GRIMSHAW, in the Chair.

AN ENTERIC RASH.

DR. J. M. DAY read a paper on a case of enteric fever in which a peculiar rash, resembling that of typhus fever, was present.

DR. J. W. MOORE said the case showed the necessity for a fever wing being attached to every hospital, as the patient in the first instance was admitted to a general ward in the Meath Hospital. When he first saw the case, he had no hesitation in pronouncing it one of typhus fever, but that it was not so, but enteric fever, the temperature chart now shown proved absolutely. He never saw a case more like typhus in the early stage. The case could not be left in the general ward, and had to be sent to Cork Street Fever Hospital. With regard to the case, he thought from the number of the spots, their unusually dark colour, and their irregular size, that they were those of typhus fever rather than an enteric rash.

DR. POLLOCK said he had seen several cases in which there was the rose-coloured rash all over the body, together with all the other symptoms of typhoid, yet they were cases of typhus. The brain became rapidly involved, and all the cerebral symptoms manifested themselves.

The PRESIDENT gave some details of a case, apparently of typhus fever, but a fatal result produced by perforation proved that the case was one of typhoid. The late Dr. Kennedy believed there were some cases of mixed typhoid and typhus fever. The President mentioned a number of cases that occurred in Bishop Street, in which both rashes

co-existed simultaneously in the same patient. He said that enteric fever was not so fatal 25 years ago as it is at present. He had never lost a typhoid patient in Cork Street Hospital, but this he did not attribute to his superior skill, but to the mild form the disease assumed at the time he was connected with that Institution; on the other hand, cases of typhus fever were then far more numerous.

DR. DAY briefly replied.

FATAL CASE OF CHOREA.

DR. JAMES LITTLE related the particulars of a case of chorea which proved fatal. The patient was a young woman, aged about twenty years.

DR. ALFRED SCOTT found at the *post-mortem* examination some very small vegetations on the mitral valve; otherwise the heart and viscera were normal. The brain was removed and sections from various parts examined. In the large ganglionic cells in the motor area of the cortex, a yellowish degenerated patch could be seen, which was blackened by osmic acid. Dr. Scott thought that this degeneration was probably caused by fatigue, resulting from the excessive choreic movements and not the cause of the disease.

DR. POLLOCK mentioned the case of a young woman, aged eighteen, attacked by chorea. This case recovered. The spasms were very marked. Bromide of potassium, 20 grs. twice daily, and 30 grs. at bed-time, gave some hours' rest, but the moment the drug was discontinued the spasms returned as bad as ever. He administered arsenic in minute quantities. There was endocarditis and a murmur. Joints were also affected.

DR. DAWSON said he would like to ask Dr. Scott at what stage in the hardening process he made the section. He considered the degeneration like that which commonly accompanied insanity. He believed it was due to over-action of the cells. He would like to know the nature of the staining substance used?

DR. BOYD wanted to know if an examination of any other portion of the nervous system, except the cortex, was made; whether the ganglia at the base of the spinal cord were examined; and whether attention was paid to the condition of the capillaries.

DR. COX gave the details of a case of chorea. It was a child. The faculty of speech was lost completely; temperature high—104°; great wasting, both of muscles of arms and body; unable to support head; food administered with great difficulty. Things looked as if the case would terminate fatally. He tried bromide of potassium, but found it of little use. What had a decidedly good effect was Easton's syrup with arsenic. The strychnine he gave, after some hesitation, in the hope of stimulating the respiratory centre, for he was alarmed lest the respiration would stop at any moment. She recovered. He believed that the spinal cord played as important a part as the brain in the production of chorea.

DR. POLLOCK said he had given strychnia in chorea, but never found it of use.

DR. KNOTT gave the details of a case, and pointed out what he considered the important circumstance about it was that the rheumatic symptoms followed the choreic symptoms.

DR. HARLEY stated the details of some cases of chorea in a children's school that came under his notice.

DR. PARSONS said chorea in persons over twenty years of age is a rare affection. The absence of pregnancy in Dr. Little's case added to its interest. He thought the vast majority of cases would recover if left alone. Only three per cent. of ordinary cases die, whereas when the disease occurs in people over twenty, according to Dr. Gowers, who had collected a large number of cases, the mortality was 20 per cent. Death, he (Dr. Parsons) thought, was due to exhaustion. He did not believe in the embolic theory. The injection of minute particles was a recognised fact; but it was difficult to see why they should select one carotid and go to one side of the brain.

DR. CRAIG gave the details of cases to show that chorea was often due to fright. In Dr. Cox's case he believed it was the arsenic did good; 5-10 minims of liq. arsenicalis thrice daily might be given to children.

DR. BOYLE dwelt on the presence of uric acid in the blood as a possible cause of chorea.

DR. BEWLEY said that by gradually increasing the doses

arsenic might be given with no harm, but with much good. As regards the pathology, he said they knew nothing at all about it, nor were they likely to do so. They were completely ignorant of changes that took place in the cells of the brain; yet something did take place to account for the impulse that travelled down to the muscles when thrown into action. The cells of the cortex appeared to him to be the seat of these changes.

Dr. S. M. THOMPSON advocated the use of chloral hydrate.

Dr. LITTLE, in reply, said, to answer the last speaker first, he might say that the first drug employed in his case was chloral hydrate, but without any good effects. After its failure he tried other remedies. Of course they all knew that the majority of cases that come into hospital suffering from chorea will get well without treatment, with treatment, or even in spite of treatment. Other cases there are that will tax the resources of the physician, and sometimes we come face to face with people with whom relief of symptoms for even a short time can be given, and thereby, as Dr. Thompson said, turn the balance between life and death. He mentioned a case, the child of a friend of his, that came under his care 18 years ago, and in her case nothing did so well as bromide of sodium at night and arsenic thrice daily. He believed that small doses of strychnia might do good in some cases of chorea. In answer to Dr. Boyd, he said the embolic theory was not originated by Dr. Hughlings-Jackson. He believed the embolic theory was now almost universally abandoned.

Dr. SCOTT, in reply to Dr. Boyd, said he had not examined the basig ganglion. He found no change in the capillary vessels, nor any changes in the medulla. In reply to Dr. Dawson, he said that at the time of section the brain was half hardened. He used blue-black, and also another form of blue stain.

The Section then adjourned.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD WEDNESDAY, FEBRUARY 5TH.

The President, Dr. ARGYLL ROBERTSON, in the Chair.

SPECIMENS.

Dr. COTTERILL showed a man with leuko-plakia of the tongue in an advanced form. There was no history of syphilis, but the man was a smoker. This condition, he said, was very easily recognised in its later stages, but it was important to be able to diagnose it during the earlier period of the disease. This was especially the case in applicants for life assurance. For his part, he would not pass anyone suffering from this complaint. Dr. Cotterill also showed an epithelioma of the larynx, which he had removed that morning. The growth was situated above the cords, and necessitated a large removal of tissue before it could be extirpated.

EXHIBIT.

Dr. DAWSON TURNER showed by means of a lime-light lantern, numerous photographs, which he had taken by the Röntgen process. They comprised the usual views of the hand, foot, wrist, and metallic objects in purses, &c. Dr. Turner stated that he had been unable to obtain satisfactory negatives with exposure of less than half an hour.

Dr. BYROM BRAMWELL read a paper on a

CASE OF CALCAREOUS DEGENERATION OF THE HEART AND ARTERIES,

with rapidly developed subcutaneous tumours in the axillæ, elbows, groins, natal folds and popliteal spaces, and symptoms suggestive of Addison's disease, in a young man, æt. 25, affected with advanced cirrhosis of the left kidney; the right kidney having been completely destroyed fourteen years ago by a pyelo-nephritis; with pathological report by Dr. Lovell Gulland. The case, which was one of great rarity and interest, was reported at considerable length, and with Dr. Bramwell's usual wealth of detail. We notice the prominent features of the case in another column.

In the following discussion Dr. W. RUSSELL remarked on the age of the patient, and said that such calcareous

changes in the arterial coats was, in his experience, unprecedented in so young a man. He had seen very considerable calcareous degeneration in a man of 33, but not to nearly the same extent. The tumours of the skin which had been handed round seemed to him to be of the nature of fibrous hyperplasia, with deposition of calcareous material.

Dr. P. A. YOUNG related a case of myositis ossificans he had seen some years ago, in a child of 6.

Dr. FOULIS thought one of the most important features in the case was the connection between kidney disease and the deposition of lime salts in the body.

Dr. ARMOUR asked if there had been no symptoms of uræmia before death.

Dr. BRAMWELL, in reply, stated that no such symptoms were observed.

Dr. A. LOCKHART-GILLESPIE read a short abstract of a paper on

THE WEATHER, INFLUENZA, AND DISEASE.

This paper was read more fully at the Edinburgh Royal Society a fortnight ago, and an abstract of it printed in our columns.

In the discussion Dr. CRAIG asked if the epidemic of 1848 was similar in type to those of the past six years.

Dr. BLACK thought that the type of weather had little to do with the incidence of any disease.

In reply, Dr. GILLESPIE stated that judging by the records of the Infirmary, the epidemics of past years were identical in their results with those lately observed.

WEST-LONDON MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD FRIDAY, FEBRUARY 7TH, 1896.

A. SYMONS ECOLLS, M.B., President, in the Chair.

THE RATIONALE OF THE ACCEPTED TREATMENT OF GOUT.

Dr. ARCHIBALD GARROD read this paper. He pointed out at the outset that very little is as yet known regarding the pathology of gout, and drew attention to several fundamental points upon which there is wide diversity of views, such as the importance of the part played by uric acid in the phenomena of gout, the causation of the accumulation of urate in the blood by excessive production or diminished elimination, the place of origin of uric acid in the body, and the substance or substances from which it is formed. The aims of treatment as far as the uric acid is concerned were next pointed out, and the therapeutic methods generally resorted to were mentioned. The bearings of such experimental researches as are forthcoming upon the diet of gouty persons, the exercise they should take, the drugs usually employed in their treatment, and the effects of mineral waters and baths were next considered, and the conclusion was drawn that we are not at present in possession of such knowledge of the pathology of the disease as would be required to enable us to formulate a scientific course of treatment. On the other hand, the belief was expressed that the course of treatment usually adopted, although largely empirical in its origin, is capable of giving great relief, and that the results obtained in the treatment of gout are decidedly satisfactory.

Dr. THUDICHUM referred to the conflicting reports of the results obtained in the various plans, dietetic and medicinal, which had been used for gout, it having been affirmed of many of them that in different hands they had done distinct good, distinct harm, or had produced no result at all. He dwelt at length on the work of Drs. Bence Jones and Roberts, and on recent researches in foreign laboratories, but he inclined to the view that clinical experience was a surer guide in the treatment of so complex a malady as gout.

After remarks from Dr. Alderson, Dr. Clemow, Dr. Masters and Mr. Atkinson,

Dr. CAMPBELL POPE expressed the opinion that in the treatment of gout the personal factor was of chief importance, for on careful investigation some obvious hygienic or dietetic fault was usually discoverable. With regard to diet he thought this should not be mixed more than could be avoided, and each particular meal should present as far as possible its distinctly nitrogenous or non-nitrogenous character as the case might be.

The PRESIDENT said that in watching the effects of physical exercise, whether taken by the gouty patients themselves or administered to them in the form of massage by others, he had found the plus excretion of uric acid not to last many days, save when the exercise taken is excessive, and then not only is the quantity of uric acid increased, but that of urea also. He then drew attention to the evidence of deficient oxidation in the tissues of gouty persons afforded by the presence of leucomaines in the urine with no increase in the amount of nitrogen excreted, and pointed out the bearings of this fact on the wider view of the pathology of gout which we may shortly be driven to adopt.

Dr. GARROD, in reply, referred to the importance of the President's researches on leucomaines, and said that possibly it might be found that while uric acid, so to speak, the indicator, leucomaines were the real cause of gout.

Specimens of renal calculi removed by nephro-lithotomy were shown by Messrs. Kestley, Edwards, and Bidwell.

LIVERPOOL MEDICAL SOCIETY.

MEETING HELD JANUARY 30TH, 1896.

The President, DR. CATON, in the Chair.

CASES.

MR. ROBERT JONES exhibited a case of "Recrudescence Ricketts" in a girl, set 16, who could walk perfectly until two years ago, when considerable epiphyseal disturbance occurred. Changes were apparent in the skull, jaw, upper limbs, sacrum, and lower extremities. The forearms presented the deformities usually ascribed to crawling, although during infancy and childhood they were perfectly straight. The family history was good, and no dietetic cause could be found for the deformities, which were very extreme. Mr. Jones did not consider such cases as rare as ascribed, having seen between twenty and thirty of them.

Dr. WHITFORD described two cases of "Pernicious Anæmia" which had recently been under his care, one in the Stanley Hospital, and the other in private. Both cases were beyond hopes of recovery when first seen, the percentage of red blood corpuscles being about one quarter of the normal. The characteristic lemon-yellow tint was a marked feature in both cases. In one of the two cases there was extensive and almost uncontrollable hæmorrhage from mucous membranes of mouth and nose; in the other no hæmorrhage of any kind whatever. In neither case was there any retinal hæmorrhage. In the hospital case a post-mortem was made. All the organs of the body were highly anæmic, and a serous fluid in all the cavities, including the ventricles of the brain. The heart was fatty, dilated, and walls slightly atrophied; spleen and other organs normal, except for the anæmia already mentioned. No atrophy of stomach. Death in both cases was due to asthenia.

Mr. THELWALL THOMAS read a short paper on

TWENTY-FIVE CONSECUTIVE CASES OF STRANGULATED HERNIA.

These included 14 inguinal, 7 femoral, and 4 umbilical. There were two cases in which omentum only was found, although acute intestinal symptoms were present. In one case omentum and sac were sloughy with cellulitis of the abdominal wall, and in one gangrene of omentum, bowel being normal. Amongst them was a case of vesical hernia in the right groin and scrotum, complicating a strangulated inguinal hernia. He advocates rapidity of operation, thorough carbolicising with 1 in 40 carbolic lotion the contents of the sac before any attempt is made at reduction, and in the after-treatment does not permit opium or ice.

Dr. BRIGGS read a paper on

ECTOPIC PREGNANCY AND HÆMATOCELE.

He founded his paper mainly on the cases he had treated by operation. There were 4 undoubted cases of ectopic gestation:—(1) Sub-peritoneo abdominal, intra-peritoneal rupture at the sixth month, sac drained, placenta undisturbed because of the state of collapse of the patient, 16½ hours afterwards, when the operation was performed. (2), (3), and (4) tubal pregnancies; intra-peritoneal rupture at the tenth, seventh, and ninth weeks. Fatality

eight day in (2) attributed to the extra manipulations in trying to arrest the bleeding before the final plugging with cyanide gauze (the broad ligament had been tied). In (3) and (4) an afebrile recovery followed; in (3) the tube and ovary were not recognised on the affected side, no ligature was used, only the plugs of cyanide gauze. There was also one instance of pregnancy in a rudimentary horn of the uterus; rupture occurred at the ninth week; recovery followed the operation which included the removal of the rudimentary uterine cornu. Four specimens of hæmato-salpinx were next considered, as the clinical histories and pathological appearances were not consistent with tubal pregnancies; in one the tube had ruptured at a thinned portion; in one the tube had nearly completely aborted through the patent abdominal ostium, in two the affected tube was dilated and laden with blood. No ovuline structures were recognised in any of them. He described cases of hæmatocele, 4 due to salpingo-öophoritis, 1 due to cystic ovaries (tubes healthy), and 1 of unrecognised origin. He also showed the apoplectic ovaries, one from each of two patients. All the cases recovered, except the one of ectopic gestation already noted. This was not a large operation experience of hæmorrhagic lesions associated with diseased ovaries and tubes; it showed that operation was not often necessary. The period covered 9 years' hospital work.

Drs. Imlach, Alexander, Davies, and Macfie Campbell took part in the discussion which followed.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, Feb. 8th, 1896.

TUBERCULOSIS.

At the last meeting of the Académie de Médecine, M. Terrier spoke on the contagion of tuberculosis, a disease which he considered to be essentially and extremely contagious. He had known of several cases where the patients contracted the malady in the hospital wards, where they were in more or less contact with phthisical patients, and it was a well known fact that a considerable proportion of the hospital nurses become tuberculous. As much might be said, almost, of the students, and especially those who work hard, remaining in the hospital several hours a day. The speaker considered that the hospital directors neglected disinfecting the contaminated wards, on the one hand, and overcrowded them on the other.

M. Debore suggested isolating all phthisical patients; the contagion of tuberculosis was an established fact, and he did not understand why persons affected with that malady should be allowed to mix so readily with other patients.

SCARLATINA.

Dr. Valli calls attention to the symptoms of vomiting occurring at the *début* of scarlatina which he considered of considerable importance in diagnosing at an early hour the affection. It permits also to recognise the malady where the usual symptoms are wanting, or where its evolution is abnormal. The vomiting occurs without any apparent cause and brusquement. The parents will tell how the child, up to then quite well, was seized suddenly, at play, during repasts, or in their sleep, with vomiting, and from that time the little patient became feverish. On examination, the pulse will be found rapid, the temperature high, and the following day the eruption and the sore throat will appear, if the affection follow the normal course. But, as remarks M. Valli, the importance of this vomiting for the diagnosis of scarlatina is the more enhanced in that it is particularly in that form of the malady where the tonsillitis and eruption are absent, that it is met with, consequently the attendant should bear in mind, when called

to such cases, the possibility of scarlatina, and make a careful examination of the urine after the fever has subsided, before allowing the patient to leave the bed, and, more especially, to go out.

ERYSIPELAS.

Dr. Chantemesse has just published a report on the treatment of 501 cases of erysipelas by serum prepared by the Pasteur Institute, with a mortality of only 2.59 per cent. The effects of the serum are both local and general. Locally, at the end of 24 hours, a marked decrease of the redness, swelling and pain, is observed. Desquamation sets in at an early hour consisting of thick epidermic scales. Sometimes the lesion continues to spread but is arrested by repeated injections. Suppuration is very rare and where it existed before the treatment it is considerably diminished by the injections.

The general condition of the patient improves rapidly a few hours after the injection; if the dose is sufficient the patient experiences a *bien être* well marked; the nervous disturbance and particularly the delirium are favourably influenced. The fever abates rapidly to disappear altogether at the end of the second day, while the pulse diminishes in frequency and increases in strength. Where albuminuria has already set in, the injections cause it to disappear within 48 hours. The gravity and the duration of the affection are diminished by the serum treatment. The ordinary doses of serum varies between six and ten drachms.

TREATMENT OF SLOW PULSE.

Dr. Debove recommends in the treatment of slow pulse, where the phenomenon provokes different grave manifestations, such as vertigo, syncope, epileptiform seizures, uræmia, &c., subcutaneous injections of a one per cent. solution of nitro-glycerine as follows:—solution 30 to 40 drops, distilled water two drachms and a half. Three fourths of the syringe are injected daily until all danger disappears. The treatment is followed up by the internal administration of caffeine, sulphate of sparteine, or other cardiac tonics.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, Feb. 7th.

A MEDICO-LEGAL CASE.

A MEDICO-LEGAL case that took a somewhat curious turn was heard in one of the local courts lately, in which a young medical practitioner of Spandau, who became qualified in 1893, was accused of causing bodily injury through negligence. In April of last year a young woman recently married presented symptoms of threatened abortion. She consulted two medical men who agreed as to her condition. She then placed herself under the care of the accused, who declared that a harmless operation was necessary. This she consented to, and the operation was performed, with the result that the patient died of hæmorrhage two and a half hours afterwards. What the operation was is not clear, but it appears to have been a curettement of the uterus, in the course of which perforation of the walls of the uterus took place. As a result of the post-mortem examination Dr. von V— was accused of culpable negligence. The two principal medical witnesses were the Kreisphysikus Dr. Reinicke and Prof. Landau. Whilst Dr. Reinicke laid the whole of the blame on the accused, Prof Landau laid it on

the present state of scientific knowledge and the defective clinical training of students. Operations such as the one in question were not taught practically to young practitioners, and they had to gain their experience from their patients. Moreover, science followed the fashions, and there was a widely spread school that had given up the plan of observation and waiting, and taught a method of treatment that the witness must characterise as brutal, and must, therefore, lead to brutal consequences. The accused appeared to belong to this modern school; the woman was, therefore, not the victim of his negligence, but the victim of the modern tendency of medicine. The Court then requested a written opinion on the matter from Dr. Landau, and at the same time a control opinion, or Obergutachten, from the Royal Medicinal Collegium. It is well to bear in mind that Prof. Landau is not an ordinary professor of gynecology in charge in either of the teaching clinics, but a professor extraordinary with a privilege of private teaching.

At the meeting of the Medical Society Hr. Stabel related the results of the

TREATMENT OF GOITRE BY THYROID EXTRACT.

These cases, 83 in number, were treated partly by fresh glands and partly by tablets from the Dresden Hofapotheke. Of the cases treated by the fresh glands, only 25 were brought forward, as only those cases that remained four weeks under treatment were made use of in the paper. For determining the size of the goitre a measurement was made at the level of the vertebra prominens. The dangerous symptoms attributable to thyroid feeding were due to decomposition of the gland. Although the glands were employed fresh, in the warm weather changes set in very rapidly, and sometimes gastric disturbances were produced; these symptoms did not come on when a better means of preservation was adopted. Baumann had succeeded in isolating the active part of the thyroid substance, had found it associated with iodine, and given it the name of thyreoiodine. In all the 25 cases of feeding with fresh substance a positive result was obtained, but in almost all of them it was to the extent of considerable improvement. A cure or total disappearance of the goitre was only obtained in four cases. Two cases only could be considered as permanently cured; 8 per cent. of the cases, therefore, were cured, and 92 per cent. improved. The cases considered to be cured had remained well nine months. The amount of diminution in size brought about by treatment was not kept up after the treatment was stopped, but a gradual enlargement again took place. A slight acceleration of the pulse was almost constant. In simple struma it was never necessary to stop the treatment on account of the increased pulse rate. Dangerous symptoms were never observed. In slighter cases, especially in young girls, a slight loss of weight was observed. A large number of cases were treated by tabloids when feeding with fresh substance was stopped, and in these the struma never increased in size in consequence of the change. In many a slow diminution took place. The results of the treatment by the Dresden tabloids were not so good as when the fresh extract was employed, the reason being that so large an amount could be given without threatening symptoms supervening. Three tabloids was the maximum dose given, in seven days, therefore, only three grammes of the active substance could be given, whilst with the fresh substance five times as much could be given. The tabloids, in addition to being less active, had a much more unfavour-

able influence on the heart. The medicine had to be interrupted on account of the increased cardiac activity caused by them. Especially in chlorotic and neurasthenic girls threatening symptoms supervened; acute dilatation of the heart was never observed under these circumstances. If the heart's action was once accelerated, this effect was kept up for weeks together. The tablets ought not to be articles of trade; cases were increasing in which they had a disastrous effect. A man, *set.* 50, who was taking them for obesity, was suddenly attacked with a psychosis with a delusion of persecution, and died in a few days with cerebral oedema.

The assumption appeared justified in this case that intoxication had been produced by the tablets, and the more so, as the speaker had observed three similar cases where delusions of persecution had also occurred. He added also three cases of morbus basedowii treated as out-patients. Two soon ceased attending, as the nervous symptoms grew rapidly worse. In one patient vomiting came on and lasted a week, with great prostration, and the symptoms returned three months later, when the treatment was recommenced. The second patient attended Mikulicz's klinik, where she was given thymus extract to loss of consciousness and maniacal attacks, and in this condition was brought back to Berlin. The third patient was treated with large doses for three months - three to four grammes daily. No change had been observed, however, although a subjective improvement took place. Seven cases of morbus basedowii had been treated with tablets, but even with large doses no other result had been obtained than an accelerated pulse up to 116 and upwards. In the older cases with exophthalmus the nervous symptoms got rather worse than better, and the ocular symptom was not affected. The treatment was directly contraindicated in Basedow's disease on account of the effect on the heart. In one case of vascular goitre with oedema, swollen pendulous lips, &c., considerable improvement took place. The goitre became smaller, and no souffle could any longer be heard. In fourteen days she looked quite different, the face had become more youthful, she felt quite well and could work hard. Subjectively she was quite contented and the struma had quite disappeared. One hundred and forty days after the treatment was stopped she returned on increasing size of the neck. Rapid effect was produced by thirty tablets daily, but the symptoms returned when the medicine was left off.

Austria.

[FROM OUR OWN CORRESPONDENT.]

Vienna, Feb. 7th, 1896.

TEST FOR ALBUMEN IN URINE.

At the *Doktoren Collegium*, Adolf Jolles read a few notes on the Various Tests for Albumen, after which he brought forward one composed of mercury, succinic acid, and hypochlorite of soda. He remarked that the test which has recently met with approbation, and is still esteemed the most sensitive, viz., the acetic acid and ferro-cyanide of potassium, had its own peculiar defects. In the first place, the intense yellow colouring which the cyanide of potassium produces in the urine erroneously betrays a higher or lower amount of albumen than is absolutely the case. In other cases it fails to indicate the presence of albumen, even where an undoubted pathological condition is present. Spiegler's is also untrustworthy and cannot be

utilised as a quantitative test where the total amount is small. It is very defective when the urine contains few chlorides and may be said to depend largely upon the presence of this constituent in the urine. Prof. Jolles considered that a good test for albumen should be free from colour and sensitive in reaction, and thought the following fulfilled these requirements:—

Hydrarg. bichlor., ʒijss;
Acid succinic, ʒv;
Hypochlorite of soda, ʒijss;
Aqua distill., ʒxv.

After filtering 4 or 5 ccm. of the urine to be tested, 1 ccm. of a 30 per cent. acetic acid solution is added, with 4 ccm. of the above reagent. The whole is well shaken and set aside to settle. In a second test tube, 4 or 5 ccm. of the urine after filtration is treated with 1 ccm. of the acetic acid as above and then set aside to settle in order to estimate the mucine present. This eliminates any error from the absolute albumen present. The potassium ferro-cyanide test is defective in this respect. The reaction is very sensitive and can detect one of albumen in 120,000 parts of urine. The reagent is free from colour throughout, which is another advantage over the potassium ferro-cyanide test. It is also superior to Spiegler's in defining accurately the amount of albumen present in the absence of chlorides.

Spiegler, in criticising the foregoing, said that he had observed a communication in the *Chemical Journal*, a few days ago, by Jolles, entitled a "Sensitive Test in the Detection of Albumen in Urine," but on examination, could find nothing novel in it. He might term it a modification of his own, but certainly there was no new discovery made. As to the defect caused by the absence of chlorides, a small addition of common salt will always overcome the difficulty in such rare cases, but the exceptions are so seldom met with that addition is unnecessary. As to the objection taken by Jolles concerning the acid, Spiegler said that he had always endeavoured to use an organic acid, finding the mineral acids unsuitable, and he, therefore, adopted vinous acid. For this Jolles substituted succinic acid, but as far as this novelty is concerned he might have substituted hundreds of others. He considered Jolles's test only a modification and founded on the principle of corrosive sublimate. Jolles, he affirmed, tells us that his modification detects 1 in 100,000, but he (Spiegler) affirmed that he could detect 1 in 350,000.

Jolles, in responding, did not deny that his test was a modification of Spiegler's, placing great importance in the use of succinic acid in obtaining accurate results.

TROPHIC NEURITIS.

Topolanski showed a patient at the *Gesellschaft* who had been bitten on the left cheek under the eye. On the third day after the lesion high fever set in which continued three days. The fever was accompanied with profuse swelling over the zygoma, and the skin became covered with large and small vesicles. For fourteen days this increased, extending over the sternum, forehead, and neck. Topolanski was unable to account for the irregularity of this morbid process. The fever was certainly in favour of erysipelas, while the continued morbid change was against this view. Erysipelas and consecutive phlegmon were negatived by the rapid disappearance of the fever on the third day, which should have continued had it been phlegmonous inflammation.

Weinlechner remarked that the vesicles around the seat of lesion would depend upon a trophic condition of the nerves, as such a state often occurred on the fingers when the nerves had been lacerated.

The Operating Theatres.

LONDON HOSPITAL.

AMPUTATION OF THE HUMERUS MIDWAY BETWEEN THE SURGICAL NECK AND THE INSERTION OF THE DELTOID—ELLIPTICAL OPERATION—Mr. H. P. DEAN operated on a man, *æt.* 54, who was found on the railway after having been run over by a train. The left arm was almost completely separated from the body opposite the middle of the humerus, simply hanging on by a lacerated portion of the triceps. The middle third of the humerus was completely ground into small pieces. On admission, the man was found to have lost a moderate quantity of blood, but he was suffering considerably from shock. By the help of stimulants and warmth, he began to improve, and amputation was performed through the humerus midway between the surgical neck and the insertion of the deltoid. Owing to the limited amount of skin left uninjured, it was found that an obliquely circular operation would be the best. As the patient's neck was too short and thick to allow of pressure being brought to bear on the third part of the subclavian, the axillary artery was controlled by rolls of bandage held in position by a tourniquet, so that the vessel was compressed at the summit of the axilla. An elliptical skin incision was made extending lower on the outer than on the inner side; the skin, with the fat and the deep fascia, was turned down to about the insertion of the deltoid, and the muscles were next divided circularly at this spot; the axillary artery and vein were tied with silk, and, on removing the tourniquet, no other vessels required ligature; the wound was stitched up with silk worm gut, and a drainage-tube, which would be removed in twenty-four hours, inserted in the outer angle of the incision. Mr. Dean said that the only question to decide in this case was whether the amputation should be performed through the shoulder-joint, or whether the surgeon should attempt to remove the limb below the surgical neck; the latter procedure, he pointed out, necessitated taking some of the skin which had been rather bruised by the injury, but in this case it was found that the third part of the subclavian could not be efficiently compressed, and it is known by experience that under such circumstances amputation at the shoulder-joint is frequently accompanied by an amount of hæmorrhage which, before it can be controlled, is often considerable. Taking all this into consideration, he thought it better to amputate through the humerus in the hope that the skin would possess sufficient vitality. Another advantage, he said, was that by this plan a roundness of the shoulder would be left, together with a considerable amount of strength in the movements connected with the scapula, as none of the scapular muscles were divided.

It is satisfactory to record that, three days after the operation, the patient is doing well; temperature normal, flaps perfectly healthy, and no sign of inflammation at the bruised part.

ROYAL FREE HOSPITAL.

OPERATION FOR PYO-SALPINX.—Mr. BATTLE operated on a woman, *æt.* about 40, who was admitted into the hospital a short time before Christmas 1895. She applied on account of a swelling in the abdomen which had shown itself a short time before; this swelling was most prominent on the left side above Poupart's ligament where the skin was adherent to it, œdematous and red. The outline of the swelling could be felt extending some

distance towards the umbilicus (about half-way) and gradually shading off on each side towards the pelvis; it was very tender, fluctuated freely, and the patient complained of much pain in it. Examination per vaginam showed a considerable inflammatory exudation round the uterus which completely fixed that organ. The temperature was raised and there were other signs of fever. It appeared as if the abscess was going to perforate at the point which was most prominent and red, and it was decided to incise this if the condition had not improved by the next visit; however, it was then thought that there was considerable improvement, the swelling being smaller and the signs of inflammation less marked. As Mr. Battle considered the case was probably one of pyo-salpinx on the left side, means were taken to diminish the inflammatory symptoms in hopes that the swelling would subside and become less adherent to the abdominal wall. Progress of the case justified this expectation, for it considerably diminished in size, became free from attachment to the abdominal wall, and the exudation into the pelvis subsided. At the operation, more than a month after admission, a central incision exposed a rounded tumour a little to the left of the middle line, crossing which obliquely, so as to reach its anterior aspect, was a greatly enlarged Fallopian tube (the size of a forefinger). The uterus could not be defined until a sound had been passed: it was then discovered below, and to the right of the swelling completely hidden by it. The intestines were placed out of the way and protected by large flat sponges, and the tumour separated from various adhesions. One part behind and below was very soft, and gave way under pressure of the finger, permitting a large quantity of thick, offensive pus to escape into the pelvis. The abscess wall and dilated tube were then separated from their attachments to the uterus and to the left side of the pelvis, the cavity left being washed out with boracic lotion and thoroughly dried with sponges, a glass drainage tube being placed at the bottom of the pelvis through the lower part of the wound. The right half of the omentum was adherent in the pelvis on the right side, and to the anterior abdominal wall to the right of the middle line; the left half which was normal was drawn across the left side of the abdomen so as to cover the bowel on that side. The wound was closed with interrupted sutures in two layers, the first including only the peritoneum, the second the structures above it. Mr. Battle considered that the operation had not only confirmed the diagnosis, but the condition of things revealed by it proved that nothing short of a radical procedure could have saved the patient's life. He thought that great advantage had resulted from the delay, as the tumour was much smaller and surrounded by less inflammatory exudation. The fresh adhesions were still soft enough to give under pressure of the finger, and the limiting wall of the abscess was firmer and better able to resist manipulation. The right ovary and tube were healthy.

A MIDWIFE was last week committed for manslaughter at the Coroner's Court, Sheffield, for attending a case of labour after having been warned against doing so. She had previously attended a case where death took place from puerperal fever, and four days after this she attended the woman whose death, also from puerperal fever, became the subject of the inquest.

WEDNESDAY, FEBRUARY 12, 1896.

MEDICAL POOR-LAW PENSIONS.

THE Bill providing for Poor-law pensions—medical and non-medical—which was introduced in the last session by Mr. Walter Long, at the instance of the English Union Officers' Association, will make its appearance again within the present week. It is being actively promoted by the President of that Association, Mr. Rutherglen, Clerk to the Kensington Guardians, and by its Council, and so much energy and forethought has been devoted by them to the matter that the prospect of passing the Bill would appear to be as favourable as those of any private Bill can be. The English Poor-law Medical Officers' Association, represented by Mr. Wickham Barnes is co-operating, and the Local Government Board Authorities of both the Liberal and the Unionist Governments have expressed themselves favourable to the principle of the measure, as are also Sir Walter Foster, Mr. Walter Long, and other influential Members of the House. The chief difficulty which confronts the promoters is to get it placed upon the Notice Paper in such a position that it will be discussed as an early Order on a Private Member's day, and, inasmuch as such privilege is conceded in turn to Private Members' Bills, by ballot, it is necessary to accumulate as many votes as possible at this preliminary ballot in favour of the Bill. In the attempt to do this the promoters have, we believe, been quite successful, and

it is, therefore, likely that the Bill will secure a “place” which will ensure for it consideration which no private bill can, under other circumstances, obtain.

This Superannuation Bill, it may be recollected, proposes to secure to every Poor-law Officer, on becoming incapacitated for duty, a pension, as a matter of right, on a scale analagous to the Civil Service scale. The pension is to be paid by the guardians and secured by them, but it is to be paid out of a fund made up of small deductions from the officer's salary, somewhat in the nature of an endowment insurance. The amount of such deduction is fixed by the Bill at two per cent. of the salary for an officer of less than five years service, rising to three per cent. for an officer of over fifteen years service. For example, a medical officer entering upon his appointment at £100 a year will have to submit to a deduction of 10s. per quarter. This deduction will continue until he has served thirty years (or for a less term if previously incapacitated by ill-health). When he has served thirty years he will, if a professional officer like a doctor, be entitled to have ten years added to his actual service for the purpose of computing his pension and will thus have credit for forty years. His pension will thus be forty-sixtieths, or two-thirds of his salary, equal to £63 13s. 4d. a year for life. He cannot, however, claim this pension (except in case of permanent incapacity from illness) until he reaches the age of sixty, so that if he commences at, say, twenty-five years of age, he will have to work on for five years after the lapse of his thirtieth year of service, while if he is not appointed until he is thirty years of age he will become entitled to pension the moment his thirtieth year has lapsed. During that thirty years he will have contributed £60 from his salary and will have acquired an eventual provision of £66 13s. 4d. for life, but upon his death at any time his contribution would disappear. It will thus be seen that the pension is to be provided on the Tontine principle under which the contributions of those who die go to increase the pensions of the survivors or—in other words—to decrease their annual deductions from salary. It would, of course, be impossible, by any other means to give a pension of £66 13s. 4d., in return for a payment of £60. It would be quite easy to frame a scheme under which the representatives of the deceased officer would get back a part of what he had paid in, but, in such case, it would be necessary to increase the deductions from the two or three per cent. set down in this Bill to some larger percentage. The Poor-law Medical Officers of Ireland occupy a peculiar position with reference to this question. At present an incapacitated officer *may* receive the Civil Service rate of pension above referred to if the guardians please to give it to them but not otherwise. A few of the richer Boards of Guardians have granted these pensions on principle to all their officers. Many others have granted them to officers who were personally or politically popular, but have refused them to others more necessitous. Many others have—on principle also—refused to grant a pension under any circumstances, and some others, of the poorest and most sparsely populated districts, though willing to

do justice to their officers, have been prevented doing so by their poverty. Thus it happens that the grossest injustice and cruel hardship has been inflicted upon the non-Poor-law Medical Officers in years past, inasmuch that for twenty-five years they have not ceased to clamour for the grant of pensions not as a matter of discretion but of right. Their efforts have, we regret to say, resulted in failure, and, as far as we can look forward, must so result as long as the object is pursued in the same way. Why? Because these Irish pensions are payable entirely out of the poor rates, and the parliamentary representatives of the money saving Boards of Guardians have always resisted the imposition of a compulsory pension upon the taxpayer. An effort was made by Mr. Gladstone's government many years ago at the instance of the Irish Local Government Board, instigated by the Irish Medical Association, to meet this objection by paying the pensions out of a general national rate and not out of a local rate, but the opposition of certain Irish members was still too strong, and the bill was then and subsequently defeated. Under these circumstances the Irish Medical Association thought it right to ascertain by plebiscite the wishes of the Poor-law Medical Officers, and they answered by a large majority that they would prefer to stand in with the principle of the English Bill than to submit to further indefinite postponement. Many of them were, no doubt, led to this conclusion by consideration of the provision which the English Bill contains that no one need come under its operation or submit to any deduction of salary who prefers to remain under the present discretionary system.

The Council of the Irish Medical Association has, therefore, taken active steps to have Ireland included in the Bill—which it was not last year—and, if this be done we may perhaps cherish the hope that the final settlement of this interminable question is within measurable distance.

THE CAMBRIDGE UNIVERSITY DEGREES AND WOMEN.

THE question of whether or not the degrees of the University of Cambridge should be thrown open to women is at present claiming a large measure of attention among those interested in the subject. The movement is under the leadership of Miss Helen Gladstone, the head of Newnham College, and the present makes the third attempt which has been made to bring about this reform in favour of the women. In so highly a conservative and academic an Institution as the University of Cambridge, it is only to be anticipated that opposition to the new scheme would be encountered, especially among those holding official positions in the University. Fortunately, however, for the friends of the women, the residents having votes in the Senate number only 550, while the non-residents number 5,000. Thus if the women are to gain the day, every effort should be made to influence the latter with the view of swamping the opposition of the illiberal-minded minority. It is of some interest to note that almost the same arguments which

were urged against the admission of women to the diplomas of the Royal College of Physicians are now being placed prominently forward as reasons against admitting women to the degrees of the University of Cambridge. The statement has been made that the granting of the B.A. degree would be harmful to the women themselves, owing to the demands upon them of the higher education, but that no harm would happen to the University, provided the concession went no further. Just, however, as certain of the Fellows of the College of Physicians were appalled at the reflection of a woman ultimately aspiring to be the President of the College, so certain members of the Senate of the University of Cambridge are horrified with the idea that women, if allowed to take the degree of B.A., would insist upon proceeding further in their University career. It is stated that they will demand to be admitted to the M.A. degree, and claim to become members of the Senate; that they will not be content with perfect equality in the University unless, and until, they invade the colleges. Such is the substance of the nonsensical arguments advanced in certain quarters against the admission of women to the degrees. On the face of it, if this is all that the opponents of the women can urge against the reform, undeniably their cause is a weak one. To argue upon these lines is really too paltry, and unworthy of those members of the University, whose academic position entitles them to be regarded as men of common sense. Another ingenious person has propounded the argument that inasmuch as there are already nine Universities to which admission is granted to women, the necessity for obtaining the same concession from the University of Cambridge cannot exist. The advocates, however, of the women point out that the latter are prepared to sacrifice much for the greater educational advantages to be derived from residence in an old University. This is quite a satisfactory and sufficient reply. It must always be so, that where the choice can be made, a University career at an old University with, say, the prestige of that of Cambridge, would prove of more value than one at a University of less note and of comparatively recent origin. We have carefully perused the statements of the opponents of the women's question at the University of Cambridge, and we have come to the conclusion that not one single objection urged against the reform is worthy of serious consideration. The position of affairs at present is that the women in their colleges of Newnham and Girton are merely in the position of guests of the University, an anomaly which should no longer be allowed to exist. Simply as a matter of justice, the degrees of the University should be thrown open to the women; in this connection, it should be borne in mind that even if the issue be against the women on the present occasion, the matter will certainly not be allowed to rest. A liberal-minded policy in regard to the higher education of women has made great progress of late years, and the time is certain to come when all the Universities and their degrees will be thrown open to the opposite sex.

THE BACTERIOLOGICAL DIAGNOSIS OF DIPHTHERIA.

It seems that virulent diphtheria bacilli may linger for an indefinite period in the mouth-secretions of persons who have recovered from an attack; indeed, in a case mentioned by Dr. Hewlett at the Pathological Society, they were detected twenty-three weeks after the onset of the malady. This observation possesses a special significance, in view of the fact that the later investigations were undertaken at the behest of a schoolmaster who feared lest the lad might, on his return to school, be the means of disseminating the disease; a well-founded suspicion, as events proved it to be. Mr. Butlin, the President, took advantage of the opportunity to review the situation in respect of the bacteriological diagnosis of diphtheria. It seems that medical practitioners in the district where he resides are now provided by the authorities with the necessary facilities for obtaining expert opinion in respect of the secretions in suspected cases, an excellent innovation one would think, but one which he nevertheless seemed to think somewhat vexatious. He also referred to the practice in the larger cities of the United States, where he assured them it had become the custom for the medical officer of health to at once visit and inspect all reported cases of diphtheria without going through the usual formality of asking the practitioner in charge to meet him in consultation. Mr. Butlin appears to dissent from the idea that the diagnosis shall be determined solely on bacteriological data, and he suggested that the society might "do something" to clear up a situation which, in his opinion, was full of danger to the public as well as to the profession. Before anything can be done, however, it will be necessary for us to know exactly what the danger is, and how it is brought about, points as to which, Mr. Butlin was silent. He questioned the importance attached by the speaker to the presence of these virulent bacilli after so long a period, and suggested that there were probably hundreds or even thousands of persons similarly inhabited by virulent bacilli wandering up and down the country apparently without detriment to the public welfare. How he arrived at the "without detriment" conclusion he did not say. It occurs to us that possibly the existence of these ambulatory foci of infection may explain the ever-increasing spread of the disease in spite of all the precautions that have been taken to check its ravages. We must confess that we do not clearly see what the society can do to clear up the situation. The Pathological Society, of all others, could hardly venture to throw cold water on the value and importance of bacteriological investigation, but unless they declare bacteriology to be a scientific fad and a delusion, it is difficult to see how they can enter a protest against its practical application to diagnosis. If the culture from the saliva of a given person is capable, as in Dr. Hewlett's case, of determining the death of guinea pigs in a few hours, even Mr. Butlin would hardly wish to introduce him to his family circle, his scepticism to the contrary notwithstanding. This being so, his protest would appear to be singularly inopportune, and, as coming from the President of the Pathological Society, somewhat regrettable.

Notes on Current Topics.

Mescal Buttons.

THE mescal plant, technically known as *Anhalonium Lewinii*, is found in certain parts of Mexico, and among the Kiowa Indians is held to possess wonderful medical and psychological properties. The plant is a small cactus having the general size and shape of a radish, and covered on the exposed surface with the characteristic cactus prickles. So numerous and important are its medical applications, and so exhilarating and glorious its effects, according to the statements of the natives, that it is regarded as the vegetable incarnation of a deity, in consequence of which ceremonial eating of the plant takes place, and this has become the great religious rite of all the tribes of the Southern plains. Despite the fact, however, that the use of the plant for medical and religious purposes is probably as ancient as the Indian occupancy of the region over which it grows, it is only quite recently that any scientific investigation has been made into its physiological effects. Mr. James Mooney, who a few years ago paid a long visit to the Kiowa Indians states in an interesting paper upon the subject in the current number of the *Therapeutic Gazette* that the mescal plant is a powerful stimulant, and enables those who partake of it to endure great physical efforts without injurious reaction. From the fact that this plant occupies so exalted a position among the natives as to have a religious ceremony associated with it, the inference is only a natural one that we should find it to possess properties which would entitle it to such an honour. But investigations into its physiological action by Drs. Prentice and Morgan are, to say the least of it, disappointing in this regard. These observers have in reality nothing very remarkable to say respecting its effects. Perhaps the most noticeable result of their inquiry was evidence to the effect that mescal buttons possessed the power of production of visions of colour, and hence it is suggested that the plant should be given a trial in cases of colour-blindness. Beyond that, however, mescal buttons might, it is stated, be useful in general nervousness, nervous headache, nervous irritable cough, colic, hysterical manifestations, and is a cerebral stimulant in depressed conditions of the mind, such as in hypochondriasis, melancholia; moreover, as a substitute for chloral and opium in conditions of great nervous irritability or restlessness, active delirium and mania, and in insomnia caused by pain. It will be conceded, therefore, that there is nothing transcendently remarkable in the plant if nothing more than this can be said in its favour. But perhaps it may be necessary to be a Kiowa Indian in order to thoroughly appreciate the virtues of this new therapeutical discovery.

Ecchymoses from Natural Causes.

IT is now a well-recognised fact that more or less considerable extravasations of blood may take place beneath the skin or of the mucosæ or on to the surface of the internal viscera from purely physiological

causes, giving rise, however, to appearances which might easily be mistaken for the results of violence in some form or another. The possibly natural origin of such ecchymoses seems only to have been recognised within the last decade or two, and this fact suggests some uncomfortable thoughts concerning probable injustice to accused persons in the past. When a certain French medico-legal authority first called attention to petechial ecchymosis on the surfaces of the lungs it was for the purpose of promulgating the view that they afforded evidence of death from suffocation in one or other of its forms. This has since been proved not to be the case, for they have been met with in connection with the action of particular poisons, particularly those belonging to the benzine series, as well as after death from burns, &c. Although these extravasations thus lose the diagnostic value which had been attributed to them, the subject is one well worthy of attention in order that full light may be thrown upon the mechanism of their production. For instance, they are not unlikely to occur in the insane, and in this event their presence on the skin would not unnaturally give rise to unfounded suspicions of violence at the hands of the attendants. In a paper dealing with this subject at a recent meeting of the Royal Medical and Chirurgical Society, Dr. Lediard laid particular stress upon the possibility of such ecchymoses on the mucous membrane of the vulva and vagina leading to the presumption of rape. Their position in the body, their delicacy of structure, and their vascularity render this portion of the female anatomy peculiarly liable to exhibit punctiform ecchymoses in virtue of the same causes that determine their appearance elsewhere. Mr. Hutchinson quoted a striking instance of the production of extensive ecchymoses in an elderly gentleman as the result of an attack of whooping-cough contracted from his grandchild. As any medical man is liable to be called upon to discharge the delicate and responsible functions of medical assessor in criminal cases, it is highly desirable that a knowledge of this curious phenomenon should be widely disseminated, for it is not difficult to imagine various circumstances in which these ecchymoses would probably be ascribed to violence or asphyxia, instead of to their real cause whatever that might be in the particular case.

The Obstetrical Society and its Certificate.

AT the annual meeting of the Obstetrical Society last week Dr. Champneys had an opportunity of discussing the negotiations between the representatives of the society and the General Medical Council in reference to the so-called diplomas of proficiency awarded by the society to women desirous of practicing as midwives. The comminatory resolutions of the Council seem to have ruffled the temper of the leading spirits of the society, and this may explain the somewhat acrimonious sarcasm which characterised the President's utterances in respect of the conduct of those who had moved the General Medical Council to take action in the matter. The society very prudently conceded all the really important points insisted upon by

the Council, the term certificate has been substituted for diploma, the size of the document has been reduced, the seal and the allegorical figure have been suppressed, and the wording has been carefully revised so as no longer to convey the impression of conferring rights which it is beyond the power of the examiners to accord. We may congratulate the society on the graceful way in which they have elected to "climb down" from an untenable position. While we fully recognise that they had at heart only the better education of midwives and monthly nurses and the welfare of the parturient population, it cannot be denied that their certificate, in appearance and wording, perilously resembled a medical diploma. The President is probably entitled to congratulate the society on the fact that the result of the fray has been to place their examinations on a firmer footing than before, in that the certificate, as at present issued, has received the *imprimatur* of the General Medical Council, and has thus been accorded an official recognition previously wanting. The need for some such proof of training is amply demonstrated by the ever-increasing number of candidates, and until Government decides, if ever this come to pass, to give legislative sanction to a more elaborate scheme for the training and examination of midwives it cannot be denied that the examination instituted by the society is a benefit to the public by enabling members to distinguish between women who possess even a minimum of knowledge, and those who only know what they have picked up, so to speak, by the road side.

Curious Death from Blood Poisoning.

THE death of a man from blood poisoning occurred in a somewhat curious manner last week. According to the evidence at the inquest held before the coroner for Central Middlesex, the man was engaged in examining a drain which had become blocked. In doing so, he took a large bar and broke the drain pipe near to the spot where he considered the blockage to be. No sooner had this been done than the retained sewage was suddenly, and with force, discharged into his face and over his clothing, some even entering his mouth. For some days afterwards, he continued to do his work without complaint. Ultimately, however, throat symptoms began to develop, and he was admitted into University College Hospital, where he soon died. The evidence of the house surgeon was to the effect that death took place from acute blood-poisoning, the result of inhaling the products of highly decomposed sewage. While in the hospital the man asserted that he could still taste the sewage matter which had gone into his mouth. A more revolting catastrophe than this could scarcely be conceived. Nevertheless, under the circumstances, it is difficult to see how septic infection could have been avoided.

The Phrenologists on Cromwell's Head.

LAST week a leader of that curious pseudo-scientific sect, the phrenologists, delivered a learned dissertation upon the reputed skull of Oliver Cromwell. After giving a full history of the relic he proceeded to the measurements of the skull, and then discussed what

may be termed his "bump" aspects. The cerebellum, he remarked, was small; a fact which showed that the intellectual powers were stronger than the animal propensities. As to this point we very much question whether there is any but the smallest variation in the actual size of the average human cerebellum. The lecturer concluded that Cromwell was well-fitted to live a life of celibacy, but that hardly tallies with the further assertion that philoprogenitiveness was extremely large. The organs of caution, secretiveness, acquisitiveness, combativeness, inhabitiveness, approbateness, and wonder were very well developed, but the largest of all was destructiveness. All this jargon is highly entertaining, although it must be confessed that such qualities as inhabitiveness and approbateness are somewhat misty and nebulous terms to the non-phrenological mind. It is certainly a grim satire on the latter-day nineteenth century intelligence that a number of people can be found to believe that the outside form of the skull corresponds with internal brain contours and local developments. The conclusion of the phrenologist that the skull was really Cromwell's is unfortunate, as coming from such a source it is calculated to rouse considerable suspicion in the minds of scientific people.

Pharmacology as an Examination Subject.

FROM a perusal of the regulations of the Conjoint Board, dated November 22nd, 1895, we gather that it has been decided that the examination in pharmacology may be passed at any time after the completion of the fourth year of professional study, provided that the student has succeeded in getting through his Anatomy and Physiology. We trust that this arrangement may be regarded as final; although we are informed that there is a desire in some quarters to tack on "Medicinal Actions" to the examination in pharmacy, and to include in the final examination questions on the "Action of Medicinal Agents on the Body in Health and Disease." If the modification were adopted, the unfortunate student would have to pass in pharmacology twice over—once at the end of the first summer session; and again, this time in conjunction with therapeutics, in the final. We trust that there will be no further change in the regulations which have been officially adopted, for this constant chopping and changing about leads to endless confusion, and is a source of worry and annoyance both to students and lecturers. Pharmacology is a subject of the greatest importance as a branch of medical study, being the foundation on which all treatment is based; and any attempt to run it in conjunction, either with pharmacy or with medicine and pathology, must of necessity prove unsatisfactory.

The Lee-Metford Bullet and Its Effects.

It will be remembered that during the Chitral Expedition the medical officers of the British forces had frequent opportunities of judging of the effects of the Lee-Metford bullet. This was the first occasion in which this new magazine rifle had been tried on active service, and consequently some report thereon was looked forward to with interest by those who had paid

attention to the subject. One of the most significant remarks made by a medical officer attached to the forces was that his experience of the wounds inflicted by the Lee-Metford bullet had led him to the conclusion that this new rifle would be probably useless in stopping a "rush." Curiously enough, this conviction has proved to be nearer the truth than was believed at the time to be likely—if the evidence of a witness of the fight at Krugersdorp is to be accepted. In the course of his description of the scene of battle he says, "The action has proved one thing—the '303 is a failure. One man shot through the chest and out at the back walked to church on Sunday; another is still alive with a bullet-wound clean through his brain, going in at one temple and out at the other. In all cases, men wounded by Martinis are having the deuce to pay, while the Boers plugged by the high velocity of the Lee-Metfords make little of their wounds. The rifle is not going to pay, for it will never stop a rush. Of course, if they could use expanding, soft-nosed bullets, well and good; but we have still some obsolete notions about humanity." The evidence, then, seems to be accumulating that while the Lee-Metford rifle is all that can be desired as a humane weapon, it does not fulfil so very satisfactorily that special purpose for which it has been designed. Practically it would seem that its perfection as a shooting machine has considerably reduced its power of killing, and that the majority of the wounds inflicted by its bullet will be such as to place the wounded person in but little peril of his life. The matter is worthy of the attention of the War Office.

Mr. Demetrius Boulger.

THE silly, hysterical, contribution from Mr. Demetrius Boulger, which appears in the current number of one of the monthly magazines, purporting to be a description of his treatment by antitoxin, when he was suffering from an attack of diphtheria, does not call for any special notice. The character of his indictment against the treatment may be judged by the fact that he attributes the post-diphtheritic paralysis, of which he became the subject, to the antitoxin. Of course, he makes the most of this grand "discovery," and says some startling things. But "playing to the gallery" does not always succeed; in this instance it is, we should imagine, destined to be a miserable failure. At all events, Mr. Boulger has not gone the right way to work to try and induce the public to imbibe his opinions.

An Extraordinary Case.

DR. BYROM BRAMWELL read an account of a most extraordinary case at the Edinburgh Medico-Chirurgical Society's meeting last Wednesday. A young man of 25, unmarried, with no history or symptoms of syphilis, and with a good family record, had led a life of considerable hardship. The only severe illness he had had previously was of an unknown nature and occurred in youth. The supposed starting point of his fatal malady was a strain of the back on lifting a heavy weight. This pain in the back did not go away with rest in bed, while similar pains occurred in other parts

of the body. When Dr. Bramwell saw him there were symmetrical hard brawny swellings in the axillæ, elbows, groins, and other places. The skin was yellow brown, simulating Addison's disease, the pulse was always above 100, and there was a slight trace of albumen in the urine, with a few pus cells, but no tube casts. A soft blowing murmur could be heard over the mitral area, and the red blood corpuscles were much diminished in number. The white corpuscles were more numerous than usual. A few days later the swellings had increased in size and hardness, the margins being surrounded with some nodules which in places ran together. The asthenia increased rapidly, the skin grew darker, the temperature was 100.2°, and the heart's action exceedingly feeble. The peripheral arteries were now found to have become in a very short time, rigid, and pulseless. Some pericarditic friction preceded death. At the autopsy, the swellings in the skin were found to be simple inflammatory over-growths with much deposition of lime salts in them. All the peripheral arteries were converted into rigid tubes, except those of the brain, while the heart was enlarged, calcareous, and did not collapse on being opened. The papillary muscles were so covered with salts as to simulate stalactites. One of the kidneys was represented by a small portion of fibrous tissue, the other was in an advanced stage of cirrhosis with an unusual amount of fibrous tissue. The attack of illness in youth had evidently been of the nature of a pyelonephritis which had destroyed one of the kidneys. The remarkable features of this case are the rapid deposition of lime salts throughout the body—this must have occurred in the course of a few weeks—the symmetrical calcareous tumours of the skin, and the fact that the patient lived so long, with such imperfect kidneys, without showing any signs of uræmia. The case will have to be taken into account in the future in any argument about the nature and cause of uræmic poisoning.

Mistaken Sex.

It is not often that Nature leaves the sex of a child a matter of uncertainty. Numerous instances, however, are on record of this elementary, yet all important detail, having been misinterpreted, and the error has, in several, been perpetuated until well on in adult life. Obviously, once an infant has been legally recognised to belong to "the female persuasion," or the contrary, it must be a delicate and even difficult matter to establish another kind of civil status. The worst fate that can befall a young gentleman born under a nebulous star, is to be constrained to wear petticoats, and to imbibe his intellectual and other acquirements in a feminine *milieu*. It is but a year or two since Dr. Fancourt Barnes, if we mistake not, showed at one of the medical societies, a young person, eighteen years of age, who had so far been accorded the deference due to supposed femininity, and it was not until certain manifestations, at variance with the code laid down for the conduct of young ladies' seminaries, had been noted, and presumably complained of, that a medical opinion was sought. This proved to be the turning point of that pseudo-young woman's

destiny, for in the result, she had to cast aside the appurtenances and bearing of the self-respecting maiden for attire and manners more in harmony with the dictum of the medical expert. The psychology of this *volte face* has yet to be elucidated. We have been favoured with a description of the young man who was made to see at nineteen years of age, having previously been perfectly blind, but his sensations, curious though they appear to have been, were probably small talk, compared with the mental and moral *bouleversement* of an abrupt change of sex, "by order." Only last week a similar error was brought to light in France, where a young woman was summoned to military service on the ground that, having been registered as a male, she must contribute, allegorically speaking, her pound of flesh. Doubtless, when it comes to the medical inspection, she (the pseudo-he) will be exempted on the ground of "palpable deformity," but red tape insists that she shall, in the meantime, "hold herself at the disposal of the military authorities," a rather dreadful fate for a right-minded young person who has been declared by competent medical authority to be a female. There are few topics that have not been turned to account by the industrious novel-writer, but here is a brand-new plot hatched ready to hand. "to be served hot." Even the title suggests itself, to wit, "The Discarded Petticoat, or Jilting made Easy."

The Registration of Midwives.

THE supporters of the Midwives Registration question are determined, evidently at all costs, to gain adherents to their views. They have now appealed to the Primrose League, the local secretaries of the branches of which have been asked to bring the "benefits" of the registration scheme under the notice of the members. Among the papers sent to the local secretaries are communications from Sir John Williams and Dr. Cullingworth, of course advocating the scheme. What an excellent advertisement for the two gentlemen named, and how much they are to be congratulated upon having taken such a public step in view of the fact that quite three-fifths of their own profession are against them.

Lecture Arrangements for 1896 at the Royal College of Surgeons, England.

THE course of lectures for 1896 at the Royal College of Surgeons, England, is the following:—On February 17th, 19th, and 21st, the Arris and Gale Lecturer, Dr. Ernest H. Starling, will lecture on "The Physiological Factors involved in the Causation of Dropsy." On the 24th, 26th, and 28th Professor Leonard E. Hill will lecture on "Cerebral Pressure and the Cerebral Circulation." On March 2nd, 4th, 6th, 9th, 11th, and 13th, Professor Charles Stewart will lecture on "The Integumentary System; its structure and functions." On the 16th, 18th, and 20th, Mr. W. G. Spencer, F.R.C.S., the Erasmus Wilson Lecturer, will lecture on "The General Pathology of Bone." And lastly, on the 18th, 20th, 23rd, 25th, and 27th, Professor J. A. Coultts will lecture on "Infantile Syphilis." The lecture hour is 5 o'clock p.m., and all Fellows and Members of the

College who desire to attend will be admitted on presentation of their private visiting card.

The New Photography in Surgery.

A LATE telegram which arrived as we are at press informs that the first surgical operation in which the first diagnosis has been made by means of the Röntgen rays was performed in Berlin on Monday last. The patient was a woman, who had broken the half of a needle into her hand two months ago, and who suffered very severe pain. With the help of a Röntgen photograph, the exact position of the fragment was ascertained, and its extraction made without difficulty.

Bone Grafting Extraordinary.

NOTHING is wasted in Nature, according to the proverb, and Mr. Waterhouse emphasised this fact in a case which he brought before last Monday's meeting of the Medical Society of London. Having found it necessary to scoop out the body of the os calcis for the removal of tuberculous disease, a foot was left, in which this important bone was represented only by a yawning cavity, bounded by a thin shell of compact bone. The outer wall of the cavity was wanting and the floor was badly damaged. This resourceful surgeon thereupon requisitioned the collar bone of a lamb (part of a shoulder of lamb which had been served for the dinner of the resident medical officers of the hospital). He decalcified the bone by steeping it in hydrochloric acid, freed it from fat by washing it in ether and then sterilised it by immersion in a solution of carbolic acid of suitable strength. The bone having been converted into chips was made into a paste with iodoform and packed carefully and tightly into the gaping cavity, over which the skin was securely sutured and the foot was then put up in an antiseptic dressing. It was not dressed again for a fortnight or so, and by that time healing was complete and has remained so ever since. We gather that this is the seventh or eighth case in which Mr. Waterhouse has employed this procedure with the same measure of success, and on this ground the method commends itself for general adoption in this class of cases. We have seen a finger grafted on to or into a nose, and a chicken bone used to patch up this or that small bone, but the utilisation of a lamb's collar bone to build up an absent heel is as interesting, and even as extraordinary, as either.

Anthrax in London.

THERE are no less than five cases of anthrax under treatment at the present time at Guy's Hospital. The patients have all contracted the disease at the same factory from the handling of goat skins. The main feature of treatment has consisted in the excision of the primary lesion. Fortunately anthrax is now almost unknown in this country as an endemic disease, and cases of this kind where the infection has been imported, are the only ones likely to come under the notice of the surgeon.

INFLUENZA is once more raging in the south of Russia.

It is proposed that in future every officer promoted to Surgeon-Major-General's rank on the Army Medical Staff shall spend three years in that rank before retirement. This will obviate the difficulty occasioned by the constant change of medical officers of districts, which has been a fruitful source of complaint for some time past among general officers in command.

AT a recent dairy show in New York cows were milked by machinery. The device obtains its power from a pulsating vacuum, imitating the sucking of a calf, which is created by an air pump in a series of pipes connected by rubber rays to the cow's teats. Ten cows were milked at once, the time consumed in milking being from three to five minutes. What next?

A CASE of small-pox recently occurred in the West-End district, and every effort was made to discover how the disease was contracted. At last it was found out that a number of circulars had been entrusted to a messenger to deliver at all the houses in the district. The bundle had been kept over night at his lodgings where small-pox had broken out.

THE "potted meat" case before the Central Criminal Court, which attracted so much attention on account of its abominable nature, was finished on Saturday last by the conviction of two manufacturers, John and Alex. Munro, on whom a sentence of six months hard labour was passed, with the option of a fine.

ANOTHER "new cure for consumption" is reported by telegraph, this time from America instead of Germany. The discovery is accredited to Dr. Cyrus Edson, of New York, and the treatment is said to consist of hypodermic injections of phenol, pilocarpine, and water.

A BUTCHER, of Salisbury, named Hart, was summoned last week by the Commissioners of Sewers, and fined £50 at the Guildhall Police Court, for sending for sale a carcase of a lamb which was diseased and unwholesome to the Central London Market.

DR. W. R. GOWERS has been appointed Bradshaw Lecturer for the current year at the Royal College of Physicians of London.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

UNIVERSITY OF GLASGOW AND QUEEN MARGARET COLLEGE.—At the time when Queen Margaret College was offered as a gift to the University of Glasgow a good deal of controversy took place, which, however, ended with the impression that the future University education of women had been solved by the Commissioners in a most progressive and liberal spirit, when by their ordinance on graduation of women the doors of the Universities were thrown open on equal terms both to men and women alike. It appears, however, that this impression was a mistake, and it is not unlikely that the incorporation of Queen Margaret College with the University will become a bone of contention. When the gift was made to the University, it carried no conditions other than it was to be used for the benefit of women only, and was thought at the time that

in medicine at least separate teaching would have to be conducted in Queen Margaret College, but that combined or separate teaching in the Arts Classes could be conducted either by mixed classes or otherwise as experience proved to be best. This understanding has, however, been called in question. In medicine, separate education in Queen Margaret College has firmly established itself, in consequence of which quite a considerable number of female students are attending the school. On the other hand, a request has been made by the female students themselves, that they may be admitted to the Arts Classes in the University, and the University Council, in April last, unanimously resolved that all the Arts Classes should be thrown open to female students, more especially as the number of such students attending College is so small it was considered incompetent to carry on separate classes for their benefit. This action has again been called in question as to the Courts legality. It may, however, be stated that at a meeting of the General Council on 4th May, 1893, a distinct and definite statement was made that "under the agreement the Court could at any time dissolve any class or classes specially at present created for teaching women, and provide that teaching in any way that was fit." There are restless spirits in the Council who are ever on the alert for points of contention and throwing obstacles in the way. When Queen Margaret College was gifted to the University, no endowment came with it, but it was collected and presented by the Council of the College. By itself, the building would be a burden on the revenue and resources of the University, as the cost of supporting it swallows up the greater part of the endowment, leaving annually only a balance of about £300. At the time when the gift was made, a certain section of the members of the Council preferred *affiliation* instead of *incorporation* for the simple reason that it would have opened the way for St Mungo's College, but in this they were foiled, in consequence of which, it may reasonably be expected that every obstacle will be placed in the way, so as to prevent the smooth working of the teaching machinery between the incorporated School and the University. It is to be hoped that matters will be amicably settled, otherwise there will be but one course open to the University, *i.e.*, politely return the "gift," which would be unfortunate. Great discretion and caution is therefore necessary in bringing about a satisfactory understanding in face of those who are apparently determined to separate, if possible, Queen Margaret College from the University.

LORD KELVIN'S JUBILEE.—A joint meeting of the representatives of the Corporation and of the Court and Senate of the University was held on the 5th inst., under the presidency of the Lord Provost, who said that he had been asked if the Corporation were disposed to take part in the celebration of the jubilee of Lord Kelvin, as a professor in the University. He had laid the matter before the Corporation, and that body having unanimously decided to assist in the celebration, had appointed a committee, consisting of five senior magistrates and himself. He wished to express the great gratification he felt that the University and the City were working together with an object which was so deeply interesting to them. The Lord Provost suggested that the celebration should take the form of a banquet, to be held in the Municipal Chambers, to be followed the next evening by a conversation at the University. It is likely the celebration will take place in the end of June.

THE PERTH INFIRMARY.—A very satisfactory feature of the annual report of the Perth Infirmary is the low mortality among the patients treated in 1895 in the institution, only 5.2 per cent., if 4 deaths which occurred within 48 hours of admission be deducted from the total. Owing to all the local authorities having adopted the Notification Act the number of infectious diseases treated has become very much greater. By an arrangement with the managers the authorities could occupy 40 beds free of charge for five years dating from 1891 on paying £1,500 towards the expense of erecting new buildings. The total number of such cases was 52 in 1891 and had risen to 233 in 1895. A further arrangement with the authorities is, therefore, absolutely necessary, especially as the hospital exceeded its income by £708 during the course of the year. In the medical officer's report reference is made to the prevalence of diphtheria in the city and county during the past year.

No fewer than 74 cases were treated in the institution, but owing to the use of antitoxin the death-rate had only been 5 per cent. compared with an average of nearly 40 per cent. for the last 18 years.

INSANITARY HOUSES.—The old time-honoured unseavoy rookeries in the cities of Scotland, once the abode of the nobility, have fallen on evil times. On every side attempts are being made to induce the working classes to migrate to more healthy quarters. During the past score of years Edinburgh has done much in this direction, but a great deal remains to be attempted. The chief difficulty in the way is the high rent charged for more modern and more sanitary flats, not that the rents for the older houses are by any means low; many are as much as £6 for one room only fit for kennels. The same difficulty is being experienced in Inverness. Many of the houses in the lower part of the town are uninhabitable, but to evict the tenants would only aggravate the evil and cause more overcrowding, owing to working-men's dwellings being so scarce. It was mentioned in the Town Council last week that one family paid £10 a year for one small room in which there was not a fireplace. The possibility of the occurrence of such a thing is a public scandal; the owner of the one apartment deserves the gravest censure. We are glad to see that the Town Council propose to take steps with the view of providing new houses for workmen at rents from £8 to £12. It is to be hoped that they will not fall into the error, which is so common, of building expensive houses necessitating high rents, which working men would rather not pay, when simple airy and well drained buildings would be much more suitable and cost much less. The erection of high priced houses of this description will not get them out of their difficulty, for many are unable to pay for them, and the lower class houses are as crowded as before, unless indeed they are pulled down, which is the only thing they are really good for.

MEDICAL SOCIETY OF LONDON.

THE meeting on Monday last (Feb. 10th) was a clinical evening. A variety of interesting cases were shown among others one by Mr. JOHNSON SMITH, of Greenwich, of a case of old standing obturator dislocation of the hip in a sailor, relieved by resection of the head of the bone. This case was followed by a similar one, also in a sailor, by Mr. W. R. TURNER, but the symptoms rendered it possible that there was a fracture as well as an obturator dislocation. The same treatment will probably be adopted in this case. Mr. MARMADUCE SHEILD availed himself of the opportunity to proclaim that the time was now quite past when a surgeon could with propriety endeavour to reduce old standing dislocations by the application of direct violence, the only scientific method being excision of the head of the bone.

Mr. COTTERELL showed a lad upon whom he had operated successfully for a large exostosis of the orbit without impairment of vision or ocular movements. He also showed a girl upon whom he had performed laminectomy of the cervical vertebrae for paralysis and disturbances of sensation consequent on caries of these vertebrae. Though he did not discover any particular disease the operation was followed by immediate return of motion and sensation.

Mr. GOODALL showed two cases of sinuses over the sacrum and coccyx which he had treated by laying them freely open and packing them with dry cotton. The interest of these cases, of which he has operated on 13, lies in the fact that the sinuses are not connected with the rectum nor with disease of the bones. Mr. SWINFORD EDWARDS concurred in this view, adding that the three cases he had operated upon on the author's plan had all proved rapidly successful. Mr. H. ALLINGHAM thought sinuses in this situation might sometimes be due to inflammation of cysts congenitally present, and he recalled a case in which he opened the abscess and dissected out the cystic lining membrane with perfect success.

Mr. J. MAORREADY showed a woman who suffered from intestinal obstruction consequent on cancer at the junction of the sigmoid flexure with the rectum. As the obstructive symptoms were acute, after ascertaining the situation of the disease by a median laparotomy, he closed the wound and did colotomy instead. Then, when the obstruction had passed off, he performed resection of the diseased portion of gut, and joined the divided ends. The woman has since been in good health, and has had no trouble at all

with the bowels, the motions passing *per vias naturales* since the artificial anus was closed. This case corroborates the conclusion arrived at by Mr. Allingham, that when there is intestinal distension it is necessary to perform a preliminary colotomy, leaving the enterectomy to be performed as a secondary operation.

Dr. OTTERBON WOOD showed a rare coincidence in three cases of congenital nystagmus in the same family. An older brother appeared to be free from the defect.

Mr. NOBLE SMITH described the treatment of fracture of the tibia and fibula in his own person by the application of strapping, early movement and early massage. The result proved most satisfactory, but how much of it was due to his excellent *physique*, and how much to this somewhat novel treatment is a matter for discussion.

Mr. WATERHOUSE showed a little girl in whom it was found necessary to remove the whole of the interior of the os calcis for tuberculous disease, leaving only a thin shell of bone, the outer surface of the bone being also completely wanting. He filled the big cavity thus left with chips of decalcified bone made into a paste with iodoform, and complete and permanent healing took place without a hitch. This makes the seventh or eighth case dealt with in this way, all having been attended with a like measure of success.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

ELECTION OF DIRECT REPRESENTATIVE FOR IRELAND.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The statement circulated last week in the MEDICAL PRESS AND CIRCULAR, and signed by the Poor-law Medical Officers, shows at least that gratitude is not dead in the hearts of those who have benefited by Dr. Jacob's hard labours. It is usual to taunt general practitioners by saying that they use up a man who works on their behalf, and kick him afterwards. I regret to say that this taunt is sometimes true. It is now in the power of every general practitioner to show that he appreciates the long and weary labours of Dr. Jacob. The practitioner who can show that by his efforts, and those who helped him, about £30,000 a year has been added to their income, is surely, even from the meanest motives, deserving of the vote of every general practitioner.

This election of Direct Representative to the Medical Council is entirely one to give medical practitioners—in contradistinction to the Universities and Colleges—the power and right to return one who will honestly represent them and their aspirations.

I hope that the two candidates who are included by the last vote of last week, will at once ask all those who promised their votes to cast them in favour of Dr. Jacob.

Dr. Jacob is a tried and well-proven candidate. He can point to actual work done, and to good efforts gained. Without disparaging the other candidates, I would honestly ask—What real and actual work have they accomplished, as compared with that of Dr. Jacob?

I am, Sir, yours, &c.,

A SUPPORTER OF REAL WORK, AND NOT PROMISES ONLY.

February 9th, 1896.

THERMO-INHALER FOR ETHER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—As Dr. Dudley Buxton has not given the explanation asked for as promptly as he made his corrections, will you permit us to call his attention to our letter in your issue of January 22nd, which has probably escaped his notice? We do not wish to be troublesome in any way; our only desire is to have the benefit of Dr. Dudley Buxton's much-valued experience, and, therefore, of his suggestions which, we hope, may enable us to remove or to make good at least some of the many grave defects in the inhaler which he found in practice

inherent in its construction. The particulars of some of the results Dr. Dudley Buxton has obtained with the inhaler would also be much esteemed, as these would help us greatly in carrying out his suggestions, by comparing them with those obtained by Dr. Carter with the same apparatus.

We are, Sir, yours, &c.,

KROHNE & SIEBEMANN.

London, Feb. 5th, 1896.

PROSPECTS OF THE WEATHER FOR FEBRUARY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—As another period of *anti-cyclonic weather* has evidently set in over the British Isles, as in last month, it may interest your readers if I draw attention to the likelihood of the weather being coincident with a *diminished rainfall* for February.

That in last month turned out to have been *under the average* for January, as there were only *ten days* in which rain fell, more or less, with an amount of fall of only 0.610-inch or less than half what it ought to have been here.

Now it would appear from experience that we are likely to have another month of *dry weather*, as statistics show the general occurrence of a dry February after a dry January.

In 1867 there were 10 *days* of rain in January, followed by only 7 days in February.

In 1869 there were 11 *days* of rain in January, followed by only 8 days of rain in February.

In 1870 January had 10 *rainy days*, and only 7 in February.

In 1871 there were only 5 *days* of rain in January, and 4 in February.

In 1873 there were only 9 *days* of rain in January, and 8 days in February.

In 1874 there were only 5 *days* rain in January, and 2 days in February.

In 1878 there were only 9 *days* in January, and 7 in February.

In 1886 there were 10 *days* rain in January, and 11 days in February.

All the years since 1886 seem to have had here fairly satisfactory rates of rainfall, and constitute a cycle of *wet winter seasons* in this country.

On the other hand, we seem to have had a course of dry years in the '70's constituting a *dry cycle* of winter seasons, most of Great Britain.

With the prevalence of this anti-cyclonic weather we may be comforted by the assurance conveyed in Dr. Gillespie's address on Weather and Disease at the Royal Society, that it may turn out to be a normal healthy month.

I am, Sir, yours, &c.,

W. G. BLACK, F.R.C.S., F.R.M.S.

United Service Club, Edinburgh, Feb. 7th.

Medical News.

Vital Statistics.

THE deaths registered last week in thirty-three great towns of England and Wales corresponded to an annual rate of 19.1 per 1,000 of their aggregate population, which is estimated at 10,591,530 persons in the middle of this year. The deaths registered in each of the last four weeks in the several towns, alphabetically arranged, corresponded to the following annual rates per 1,000:—

Birkenhead 17, Birmingham 22, Blackburn 18, Bolton 22, Bradford 14, Brighton 16, Bristol 15, Burnley 20, Cardiff 16, Croydon 14, Derby 14, Dublin —, Edinburgh —, Glasgow —, Gateshead 15, Halifax 17, Huddersfield 17, Hull 17, Leeds 20, Leicester 21, Liverpool 19, London 15, Manchester 21, Newcastle-on-Tyne 19, Norwich 19, Nottingham 18, Oldham 22, Plymouth 17, Portsmouth 18, Preston 20, Salford 20, Sheffield 21, Sunderland 16, Swansea 15, West Ham 16, Wolverhampton 15.

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

LOCAL REPORTS AND NEWS—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

REPRINTS—Authors of papers requiring reprints in pamphlet form after they have appeared in these columns can have them at half the usual cost, on application to the printers before type is broken up.

READING CASES,—Cloth board cases, gilt-lettered, containing twenty-four strings for holding the numbers of THE MEDICAL PRESS AND CIRCULAR, may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

MR. RICHARD LARR.—We hope to have space for your paper on "Excision of Ossicles and Membrane in Chronic Suppuration of the Middle Ear" in our next.

DEAN FARRAR is thanked for his courteous note.

MR. CLEMENT SEAM.—We do not care to prolong the discussion, as the subject is somewhat *ultra vires*, and the point is included in previous correspondence.

MR. R. E. PARKINSON (Clithero).—The case is of almost daily occurrence, and there is no feature connected with that to which you draw attention deserving of exceptional reference. Dr. M— did what every right-minded medical man would do under similar circumstances.

THE NOTIFICATION CASE—MASON V. HADDEN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—With reference to my letter in your issue of Jan. 22nd, I fear that a portion of it may be open to misconception.

After the recent decision of the full court in Dr. Hadden's favour, he was appealed to by the plaintiff not to press for his costs, and he, accordingly, instructed his solicitors not to ask payment of the same from the plaintiff.

I am, Sir, yours, &c.,

JAMES CRAIG, Hon. Sec. and Treas.

85 York St., Dublin, Feb. 8th, 1896.

MR. A. YOUNG.—We should advise our correspondent to refer the matter to his solicitor, and be guided by him before taking any active steps. The legal position does not appear to be plain.

GENERAL PRACTITIONER.—It is not clear that any impression has been made on the mortality from phthisis by the gualcol or creosote treatment.

Meetings of the Societies.

WEDNESDAY, FEB. 12TH.

LARYNGOLOGICAL SOCIETY OF LONDON (20 Hanover Square, W.).—5 p.m. Discussion on the Nature of Laryngeal Ulcerations during the course of Typhoid Fever, to be introduced by Drs. A. A. Kanthack and J. A. Drysdale.—Discussion on Foreign Bodies in the Upper Air and Food Passages, to be introduced by Mr. Charters Symonds.

THE SANITARY INSTITUTE (Parkes' Museum, Margaret Street, W.).—8 p.m. Dr. S. Monckton Copeman will open a discussion on The Influence of Subsoil water on Health.

HUNTERIAN SOCIETY (London Institution).—8.30 p.m. The Hunterian Oration on John Hunter and Some of his Contemporaries, by Dr. G. Newton Pitt.

THURSDAY, FEB. 13TH.

BRITISH GYNECOLOGICAL SOCIETY (20 Hanover Square, W.).—Specimens by Mr. bowreman Jessett, Dr. Alfred Smith, and Dr. E. T. Smith. Dr. Elder: Notes on a Supra-vaginal Hysterectomy during Pregnancy, performed because of threatened intestinal obstruction (with Specimen). Dr. George Keith: The Permanent Cure of Antiflexion by Operation. Dr. E. F. Elliot: Notes on Gynecological Cases from a Provincial Hospital.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY (Great Northern Central Hospital, Holloway).—9 p.m. Dr. A. Morrison: Cardiac Dyspnoea. Drs. Harry Campbell, Burnet, Christie, Ostlere, Alex. Reid, and others are expected to take part in the discussion on this paper.

FRIDAY, FEB. 14TH.

CLINICAL SOCIETY OF LONDON.—8.30 p.m. Mr. T. W. Nunn: A Case of Chronic Cancer. Mr. Pitts and Mr. Ballance: On Splenectomy for Rupture, with three successful cases. Dr. Hale White: Two cases of Pneumothorax in the course of Typhoid Fever, and both due to straining at stool. Mr. Golding Bird: A case of Lymph Scrotum and Lymphatic Varix.

Vacancies.

Bristol General Hospital.—A Surgeon on the Hon. Staff. Applications

to the Secretary before Feb. 19th. Rules relating to the office may be obtained.

Cardiff Union.—Assistant Medical Officer for the Workhouse, under the direction of the Medical Officer. Salary, £100 per annum, with rations, apartments, attendance, and washing. Applications to Arthur J. Harris, Clerk, Queen's Chambers, Cardiff.

Cumberland Infirmary, Carlisle.—An Assistant House Surgeon. Salary £40 per annum, with board, lodging, and washing. Applications to the Secretary before Feb. 25th.

East London Hospital for Children, Shadwell.—House Physician. Board, lodging, &c., are provided, but no salary. Further particulars from Thomas Hayes, Secretary.

Liverpool Royal Infirmary.—Assistant Honorary Physician. Applications to the Chairman of the Committee of the Royal Infirmary, Liverpool.

Naas Union.—Medical Officer. Salary £130 per annum, and £15 per annum as Medical Officer of Health, with fees. Election Feb. 19th. (See advert.)

Salford Royal Hospital.—House Surgeon. Salary £100 per annum, with board and residence. Applications to the Secretary by Feb. 22nd.

Stevens' Hospital, Dublin.—Gynecologist. Applications to the Governors and Guardians by Feb. 20th.

Western General Dispensary, Marylebone.—Two House Surgeons. Salary £70, or £50 with board and residence. Applications to the Hon. Sec. by Feb. 17th.

Westminster Hospital.—Surgeon on the Hon. Staff; must hold the F.R.C.S. Eng. Full particulars of Sidney M. Quennell, Secretary.

Appointments.

ALLEN, W. T. D., M.B., B.Ch., B.A.O.I., Assistant Medical Officer to the Parish Infirmary, Brownlow Hill, Liverpool.

ATKIN, C., F.R.C.S. Eng., Surgeon to the Sheffield General Infirmary.

BRIDGES, S., M.B.C.S., L.R.C.P., Assistant House Surgeon to the Devonshire Hospital, Buxton.

COOKE, W. C., L.R.C.P., L.M. Edu., M.R.C.S., Medical Officer of Health to the Bognor Urban Council.

COLVILLE, J., B.A., M.D., R.U.I., Anaesthetist to the Ulster Hospital for Children and Women, Belfast.

DIXON, F. J., M.A., M.B., B.C., Camb., Assistant Registrar to the Central London Throat and Ear Hospital.

EVANS, W. H., M.D. Lond., F.R.C.S. E., Assistant Surgeon, with charge of Skin Department, to the Royal Free Hospital.

FLEMING, Mrs., M.D. Lond., Medical Registrar to the Royal Free Hospital.

FORBES, T. D., M.B., Ch. Ed., Assistant House Surgeon to the Royal Albert Hospital and Eye Infirmary, Devonport.

HANBURY, W. E., L.R.C.P., M.R.C.S., Second Assistant Medical Officer to the County Asylum, Dorchester.

HARDMAN, F. H., M.B., O.M. Edin., Medical Officer for the Knighton Sanitary District of the Knighton Union.

HARDYMAN, G., M.B., C.M. Edin., Honorary Surgeon to the Royal Mineral Water Hospital, Bath.

HARRISON, E., M.B., Ch.B. Vict., Medical Officer to the Birmingham General Dispensary.

HEATH, C. J., F.R.C.S., Assistant Registrar to the Central London Throat and Ear Hospital.

MOORE, T., M.R.C.S., L.M., Medical Officer of Health for the Stockport Rural Sanitary District.

NOUBE, W. J. C., F.R.C.S. Edin., Assistant Registrar to the Central London Throat and Ear Hospital.

REID, St. G. C., M.B.C.S., Surgeon in charge of the Bacteriological Department of the Central London Throat Hospital.

SHARF, W. A., L.R.C.P. Lond., M.R.C.S., Resident Medical Officer to the Royal Hants County Hospital, Winchester.

SINGLAIR, W. W., M.B. Aberd., Honorary Ophthalmic Surgeon to the East Suffolk and Ipswich Hospital.

THOMAS, J. T., L.R.C.P. Lond., M.R.C.S., Medical Officer of Health by the Camborne District Council.

Births.

LIEWELLYN.—Feb. 6th, at 87 Earisfield Road, Wandsworth, the wife of John Liewellyn, M.B.C.S. Eng., of a daughter.

MAJOR.—Feb. 6th, at Clulow House, London Road, Reading, the wife of Arthur C. Major, M.B.C.S., L.R.C.P., of a son.

MATTHEY.—Jan. 23rd, at Georgetown, Demerara, the wife of Arthur Matthey, M.B.C.S., of a son.

ROBERTSON.—Feb. 4th, at Christ Church Road, Tulse Hill, S.W., the wife of John Robertson, M.A., M.D., of a daughter.

WIGGLESWORTH.—Feb. 6th, at Washam, Kirkham, Lanca., the wife of Sidney Wigglesworth, L.R.C.P., M.B.C.S., of a son.

Marriages.

FISHER—MEDLAND.—Feb. 4th, at St. Peter's, West Leigh, Devon, William fellows Fisher, M.B., of Dudley, to Mary Edith, third daughter of the late Rev. William Medland, M.A.

LISTON—COOPER.—Feb. 1st, at the St. Marylebone Parish Church, London, Walter Lawrence Liston, M.D., of Tewkesbury, to Kathleen Nora Cooper.

THOMPSON—SIDNEY.—Feb. 6th, at Washingboro' Church, Percy Walker Thompson, M.B., third son of T. Thompson, Esq., J.P., of Nosedale, Toronto, to Fanny, eldest daughter of the late George Sidney, Esq., Reighton.

Deaths.

HEWBY.—Feb. 1st, at Cambridge Gardens, London, W., John Fetch Hewby, B.A. Oxon. M.R.C.S., aged 61.

WALL.—Jan. 11th, at Carrick-on-Suir, G. A. Wall, L.R.C.P.I., L.R.C.S.I., aged 41.

TUBERCULAR DISEASES OF THE HIP-JOINT.

By R. L. SWAN, F.R.C.S.I.,

Surgeon to Stevens' and The Orthopedic Hospitals, Dublin.

(Concluded from page 159.)

It will be convenient to review those circumstances which will enable us to form an opinion as to the probable position of the deposit. Acetabular disease may, I believe, occur in three ways. 1st. As an extension to the joint of a tubercular mass in the cancellous structure of the pelvis, having a beginning quite unconnected with the articulation. 2nd. From an injury caused from transmission of force by impact of the head of the femur, and producing a slight traumatism which sets up acetabular disease; and 3rd. By extension of disease primarily commencing in the synovial membrane or transmitted thereto by the caseation and rupture of a femoral deposit into the joint. The symptomatology in such a case will be positive and negative. The positive signs will be the situation of the pain which as observed by Erichsen will be in the iliac region, or back of the thigh, and pain on digital examination per rectum of the inner pelvic surface corresponding to the acetabulum. This valuable symptom was first pointed out by a French surgeon, M. Cazin. At a period when the disease has somewhat progressed this surface may be found thickened in comparison with that of the opposite side, and may impart a doughy or softened sensation to the finger, from the presence of extravasated lymph or pus. As regards the reflex muscular starting, it appears to be common to every incidence of disease, and is, I believe, due to irregular interarticular pressure. At a later period the position of abscess, whether intra-pelvic or gluteal, or outside the thigh, will aid in establishing the situation of disease. The negative signs will be: The absence of thickening in the neck of the femur or trochanter, unless the disease had primarily begun in those tissues, and a comparative absence of deformity in the early stages.

That the tubercular deposit may sometimes originate in the ligaments of the joint there is no reason to doubt. Some recent writers, among them Mr. Edmund Owen, consider that the ligamentum teres is most frequently the starting point. It was demonstrated by watching the movements of the joint structures through a hole made in the acetabulum from the pelvic side that this ligament checks adduction of the partially flexed thigh. If a child fall, therefore, on the outer side of the partially flexed thigh, he may strain this ligament. If healthy, a simple synovitis, which a short rest will cure, is the result; but if otherwise, the ligament becomes thickened with inflammatory exudation, and after a time incorporated with the contiguous synovial membrane in tubercular infiltration. In such a case there will be deformity, flexion, and abduction, pain at the inner side of the knee. There is an elastic resistance to the rectification of flexion due to the bag of fluid existing within the joint. There may not be any marked pyrexia. If the trochanter and neck of the

femur be thickened, and only a moderate amount of pain be present with some lameness, it is probable that the deposit is in the neck of the femur, or at or outside the line of the epiphysis. If, as a sequence to a condition such as this, there be a sudden accession of acute symptoms, with fulness in the groin, and fixation in the joint, it is to be inferred that the articulation has been invaded. That the cartilage thinned by pressure has given way, and that the joint is filled with sero-pus. In such a case there is prominence of the structures in front of the joint. If a calliper be taken it will be found on measurement that the region of the femoral artery at the base of Scarpa's triangle is more advanced than the corresponding portion at the healthy side. There is generally abduction of the limb. There are usually blue venous radicles ramifying over the region of and below Poupart's ligament; indicating pressure. There is pain; starting; and pyrexia. It is convenient at this point, as we are often consulted when the conditions just related exist, to consider the line of treatment to be adopted, and the most important questions to decide are: Should we choose an expectant treatment, or should operative measures be preferred! When the condition of suppurative arthritis is recognised. When there is fixation, flexion, pain, and pyrexia, I do not hesitate to open the joint. This may be done under anæsthesia from behind through the gluteal fibres, or through the fascia in front of the tensor vaginæ femoris. A long narrow knife by which a free opening may be made into the capsule is best. It is often remarkable what relief will be at once given by this expedient. Not only is the pain relieved, but the general symptoms subside and extension of the limb may, if thought desirable, be at once adopted, but for reasons to be hereafter given this is not always expedient. I have in many instances repeated this measure in the same case, when signs showed a re-accumulation of the fluid, with benefit. Mr. Edmund Owen has advised the tapping of the joint by a trocar and cannula from behind through the gluteal fibres, or from beneath the anterior superior spine of the ilium, working inwards, and Mr. T. N. Fitzgerald, of Melbourne, passes a tenotomy knife into the articulation, allowing the fluid to escape into the surrounding tissues and so to be absorbed. If on opening the capsule with a knife, pus appears along its side, I make a practice of passing in a long sinus forceps into the cavity, and enlarging the canal by divaricating its blades, washing it thoroughly with boric solution, and plugging it with iodoform gauze. At the same time the patient must be kept at rest, and extension should be maintained. I here venture to make a few observations on this well-known subject. The theory that I have long held myself is—That it does good by the diminution of intra-articular pressure it affords if properly applied.

It is that pressure which produces muscular spasm, and by its removal the spasm is averted. This is proved by the fact that extension, if not applied in the axis of deformity, will increase spasm; in other words, although extending the muscular element, it increases intra-articular pressure, and is, therefore, useless. That this theory is practically correct may be deduced from the observations of E. H. Bradford, and R. W. Lovett, in a paper entitled "A Study of Traction in Hip-

Disease." The evidence presented by them was, experimental, pathological, and clinical.

In a number of dissecting room adult cadavera the legs were slightly flexed and abducted, and a weight varying from 50 to 60 lbs. was attached to the legs. It was found that the limbs could be lengthened three-quarters of an inch. It was found that no amount of force produced separation of the joint surfaces in adults if the legs were kept quite straight.

The hip of a foetus at full term was prepared in such a way that the skin was removed so as to expose the muscles round the hip. It was found that under a slight amount of traction separation was possible. A needle was inserted into the head of the femur, another into the ilium a little above the acetabulum—a slight traction caused a separation of the needles.

Traction separated the joint surfaces in all cases in children, dissected or otherwise. and the checks to separation in adults lay in the resistance—1st, of the capsular ligament, and especially of the anterior bands of the ilio-femoral ligament; 2nd, in the resistance of the cotyloid ligament, and to a slight degree to atmospheric pressure.

In children the lower edge of the acetabulum presents no resistance to traction in the axis of the body. In adults this presents a resistance which is avoided by abduction of the limb.

Both in children and adults, if the femur be extended to its utmost limits, the anterior bands of the ilio-femoral ligament prevent distraction by any force which can be applied with safety. In a diseased joint, where the capsule and cotyloid ligament are disorganised, distraction is easy.

Experiments were also made on healthy joints in living persons, and it was found that 20 lbs. weight produced in a girl, *æt.* 7, one quarter of an inch in lengthening, due to separation of joint surfaces.

In diseased joints 10 lbs. produces lengthening invariably by separation of joint surfaces before puberty, but the extent varies in different individuals, and is, as a rule, less in older children than in young ones.

The pathological evidence embraced cases where traction had been employed, and where it had not, and showed the different results; in the one case a preservation to a great extent of the head and neck of the bone, without displacement; in the other, the wandering acetabulum, with displacement upwards and backwards of the head of the femur, which had itself undergone destructive changes. The results arrived at by those investigators seem to prove:—

1st. That traction properly applied draws apart the articular surfaces both in the dead and living.

2nd. A greater force has to be applied than has commonly been used in hip-joint disease. Separation is less likely to occur in the adult than in the child and more likely in diseased joints than in healthy ones. Separation is more easy in a flexed and abducted position of the limb than in full extension.

3rd. Pathological evidence demonstrates that the upper edge of the acetabulum and the head of the femur are eroded in hip disease where traction is not used.

Clinical evidence shows in routine hospital practice the absence of subluxation after the use of traction. In my experience I find that the weight used must, to a great extent, be regulated by the comfort afforded. For a child under ten years of age from three to nine pounds may be defined as the limit. I have adopted the plan of making the extension altogether above the condyles by placing a plaster-of-paris case outside padding applied to those processes and attaching webbing bands thereto. By leaving this webbing free below the knee two advantages are acquired. 1st. The knee-joint itself is not weakened, I have known it converted by extension of the ligaments into almost a diarthrosis; and 2nd, the knee may rest on a pillow

and remain semiflexed, such a position not interfering with the line of traction in axis of the deformity and affording great comfort to the patient. In many

1.—A small device for attaching stirrup for traction.

2.—Board for graduating pulley. To be slipped under mattress.

3.—Extension applied by means of plaster-of-paris bandages.

4.—Pelvimeter for estimating alteration in position of trochanters.

instances when extension has overcome deformity and starting has ceased, pain will return. This is caused by the overstretching of the inflamed ligaments, and in such a case the lessening of weight or its complete removal will afford relief. In such a case it will be prudent to secure fixation of the joint by a splint.

In cases where rarefying osteitis is present and where an arrest of development of the femur may be anticipated and consequent shortening of the limb, it is better to encourage a slight adduction. As a result

the shortening is of less importance than it would have been had ankylosis taken place in an abducted position. Sometimes, however, it is not possible to prevent abduction by traction in the axis of the limb or towards the other side, as it is almost impossible to prevent by any appliance the spinal accommodation which ensues. It is remarkable how even a very young child will extricate himself from the restraint of an irksome position. To obviate this I have found that a combination of lateral traction, by fixing the upper portion of the femur will allow of the downward traction being applied in the direction of adduction. If extreme adduction occur, as may be seen in cases of absorption of the head of the bone, or subluxation, or in cases of double hip-joint disease, of which a good example was in the Orthopædic Hospital a short time ago, a crossed-legged progression may result. In such cases much improvement may be made by the careful use of Thomas's double splint or of Phelps's box. It is important, however, in the application of traction for the rectification of deformity the result of tubercular trouble, to remember that we are dealing with diseased tissues in which lives a latent enemy easily aroused, and to proceed with the utmost gentleness.

Rotation, either inward or outward may be controlled in a variety of ways. Sandbags will usually suffice if there be a careful nurse in attendance. A piece of splint wood fixed by the plaster bandage behind the thigh and adjusted so that the patella must look straight in front, or a zinc trough moulded to the limb with two cross bars to prevent rotation, will effect the same purpose.

A question will arise. At what period may fixation alone be substituted for fixation and extension? We must be guided by the progress of the case, but my personal feeling is, that while I have never regretted maintaining extension for a lengthened period, even when it appeared unnecessary to the parents and even to the patient himself, I have often had cause to regret leaving it off too soon. Even when progressive disease has been arrested, the weakened elements of the damaged joint are easily influenced by muscular contractions or by extraneous causes, more especially if what is termed the ambulatory method of treatment be permitted. The temperature which perhaps for months has been normal will rise a little at night. Flexion at the joint will recur, and extension has again to be applied:—if pain be entirely absent; if muscular starting has altogether ceased and the limb be in a good position; if the general appearance and condition of health indicate that the disease is at a standstill; if there be no evidence of suppuration; if the digestion be good, the sleep sound, and the temperature normal, we may then direct our attention to the question.

Incomparably the best as a fixation apparatus in my opinion is a Thomas's splint; I need only allude to this well-known and useful apparatus, which is unfortunately often seen applied in a careless and inefficient manner.

A few words regarding the deformities met with during the existence of hip-joint disease. Flexion is a constant occurrence, and will be met with in all cases irrespective of the position of the diseased focus, but it will occur with greater rapidity when the synovial membrane is engaged and intra-articular effusion sets in. It seems to be a position instinctively assumed to lessen joint pressure. The deformity can be induced in the cadaver by injecting the joint through a hole in the acetabulum, and the mechanics of the phenomenon observed. It will be seen that the anterior part of the capsule, owing to the identification with it of the strong fibres of the ileo-femoral ligament, is dense and unyielding, but the posterior part is comparatively thin. On injecting a moderate quantity of fluid into the joint flexion occurs, and by increasing the amount a slight degree of abduction. I used glycerine myself in

making the experiment, being a fluid probably of consistence approaching that of the majority of intra-articular effusions. By tightly plugging the opening with a piece of indiarubber it was easy to observe the elastic feel which fluid in the joint imparted on attempting to extend the limb, and the intra-articular pressure produced thereby indicated by the difficulty in retaining the plug of indiarubber in position from pressure on its articular aspect.

At a later period, owing either to changes in all the structures of the joint, or to changes in the acetabulum, or to an alteration in the normal position of the head of the femur, adduction and rotation inward may happen. To the deformities of abduction and adduction is due the apparent shortening which is produced by the tilting of the pelvis. This may be estimated by comparing the measurements from the umbilicus to the internal malleolus on either side. Real shortening may occur; 1st, In acetabular disease from recession of the head of the femur; 2nd, From the displacement of the upper extremity of the femur consequent on so-called wandering acetabulum, or from a partial or complete dislocation of the head of the bone, which last is a rare occurrence. It may also happen from a shifting upwards of the acetabulum *en masse*, from a softening of its base, as I saw in the case of a boy, æt. 9, in Steevens' Hospital a few weeks ago, where it was necessary to amputate through the joint.

To causes referable to the femur. 1st, To absorption of the head or its removal as a sequestrum. To absorption of the neck, and lastly to an arrest of development of the femur, which may continue when the disease has ceased. To so great an extent may this arrest of development proceed, that in the case of a girl, æt. 18, of otherwise large proportions, who was bedridden for thirteen years, from extensive disease of the head and neck, and the femur and the acetabulum, and whose limb was removed from the pelvis, I found the femur, about the size of a radius, to which bone it bore a considerable resemblance. To estimate real shortening a line must be taken from the anterior superior spine to the inner malleolus, but it is important in making such a measurement, to place both legs in exactly the same position as regards flexion, abduction, or adduction, otherwise the measurement will be inaccurate. The upper margin of the trochanters normally touches Nélaton's line. The vertical measurement of any part of the trochanter which reaches above this line will indicate the shortening due to alterations in the head or neck of the bone. If the real shortening exceed this, the excess will be due to arrest of development in the length of the femur.

The position of the trochanter as regards the median line is significant. This may be measured by the small pelvimeter of which an illustration is annexed, No 5. The trochanter on the diseased side may be pushed out further than the other. This may be due to articular effusion, to serum or pus in the joint, or to an obliteration of the cavity of the acetabulum by a cell proliferation in the ligamentum teres. In dislocation on the dorsum ilii whether from acetabulum alteration or otherwise, the same thing may happen, but in such a case, the trochanter will be on a higher level than normal.

The trochanter will be nearer to the median lines either from absorption of the head or neck of the bone, or from disease of the acetabulum which has allowed a recession of the head into that cavity. This may be diagnosed by an examination through the rectum. At a later stage of the disease, and when acute symptoms have ceased, the trochanter at the diseased side may be found to approximate the median line more than its fellow. This will be due to arrest of development of the upper extremities of the femur, and may not have been observable during the existence of the disease in an acute form.

Lectures

ON

THE DIAGNOSIS OF INSANITY.

By THEO. B. HYSLOP, M.D.,

Lecturer on Mental Diseases to St. Mary's Hospital Medical School,
Assistant Physician to Bethlem Royal Hospital.

LECTURE VIII.

In this lecture I propose to deal with the subject of insolation as a factor in the causation of insanity, and it will be seen that the effects of a continued high degree of temperature upon the vital processes of man are very important and far-reaching. I do not propose to discuss the symptomatological aspects of insolation; but deem it advisable to consider somewhat in detail its etiology and sequelæ, and of the sequelæ I shall confine my attention more particularly to the mental defects and aberrations commonly met with in the insane.

The multiplicity of terms derived from the etiology, symptomatology, and pathology of insolation is liable to cause confusion, but the recognition that some of the numerous terms apply mainly to the several degrees of the same affection will serve to simplify matters. We have the terms sun fever, thermic fever, ardent fever, cerebral fever, cephalitis *Ægyptica*, coup de soleil, heat asphyxia, heat apoplexy, ictus solis, erythismus tropicus, causus ab insolatione, phrenitis indica, typhomania, calenture, &c., and also various combinations, varying according to the modes of causation.

Morache has conveniently divided the forms of insolation into two classes, (1) *Coup de soleil*, or sunstroke due to direct rays of the sun, and (2) *Coup de chaleur*, or indirect form, due to heat and other influences. Of the two forms, the latter appears to be the more common. In fact, the former, without the aid of a greatly heated atmosphere and other causes, such as humidity, &c., is seldom met with. A lengthy account of the atmospheric influences, together with the relative value of heat, humidity, and the influence of the various winds, as a cause would be out of place here; for although high temperature, rarefaction of the air with its direct sedative effects, quick evaporation from and inspissation of the blood, result in venalisation of the blood from diminution of the supply of oxygen at each inspiration, yet fatigue, faulty bodily habits, excesses (alcoholic, dietetic, or sexual) form the most important etiological factors. Wallther's experiments show that the heat from the streaming rays of the sun can be actually absorbed by the skin. Most authors, however, agree that it is by the combination of the sun's rays, a heated atmosphere, and a relative amount of humidity, acting together, that heat is retained in the body. As a true exciting cause, heat both direct and indirect may be an effective cause, but hygrometric and barometric states of the atmosphere have a special influence upon the general vigour of the constitution, and not only render a person more or less susceptible to heat, but also predispose him to suffer from it.

The difficulty in estimating the exact effects of the solar rays is not only due to the absence of a sufficient number of experiments, but also by the presence of other conditions, such as hot, rarefied, and perhaps, impure air, and heat of the body produced by exercise, and not attended by perspiration. Eckhard found that when a temperature much over the natural amount was applied to the nerves of frogs, the electrical currents through them were ultimately stopped. Weber also found that the same rule held good for men. Solar heat as an immediate or exciting cause may act in two ways, causing (1) prostration of nervous powers and syncope, with symptoms of debility, vertigo, weariness, nausea and incontinence of urine; or (2) venali-

sation of blood, with absence of perspiration, suppression of urine, and constipation. The latter group is aided chiefly by fatigue, impure air, alcohol, visceral disorders, and retained secretions.

Respirations are said to be lessened during hot seasons, and the higher the temperature, the less oxygen there is going into the system and the less carbonic acid exhaled. When isolation is established, the other organs are hindered in their action as compensatory excretors. Moore^(a) has pointed out that formerly many cases were not returned in India, but were overlooked owing to the fact that only those cases occurring after direct exposure to the sun were recorded. Dr. Tripe, at the Conference of the Royal Meteorological Society, in July, 1884, in discussing some of the relations of meteorological phenomena to health, pointed out that the effects of high temperature vary much according to the amount of moisture in the air, as when the air is nearly saturated in hot climates, or even in summer in our own, more or less languor and *malaise* are felt, with great indisposition to fatigue. With a dry air these are not so noticeable. In the former case, but little evaporation from the skin occurs, and the normal amount of moisture is not given off from the lungs, so that the body is not cooled down to such an extent as by dry air, sunstroke probably being the result, not only of the direct action of the sun's rays, but partly also from diminished cooling of the blood by want of evaporation from the lungs and skin.

Undoubtedly, hot climates eventually sap the foundations of life amongst Europeans, and although the hypothesis of acclimatisation, *i.e.*, that an injurious effect is first produced, and then accommodation of the body to the new condition within a limited time, is to a certain extent true, yet the rule does not extend to the progeny. In fact, it appears that acclimatisation of Europeans in India depends to a great extent upon the intermixing by marriage with the natives; otherwise, they do not reach beyond the third generation.

The effects of a tropical climate are, so to speak, relative, and beyond the conditions of temperature and humidity, we have to take into consideration the malarial influences arising from the putrescence of organic matter, and the effluvia from impure soil, which in their turn cause malarial fevers and other conditions equally fatal to human life.

Various winds prove dangerous to human life and tend to produce deleterious effects upon our nervous systems. The Scirocco of the North African Coast, Sicily, and Southern Italy, is a hot, dry, south-east wind, and blows from the heated Sahara passing over the Mediterranean where it absorbs a large amount of moisture becoming a hot moist wind on reaching the South of Europe, which causes languor, listlessness, and heat-stroke. The Leveche or Scirocco of Spain, and the Solano, are both productive of much nervous prostration. The Harmattan of the West Coast of Africa from the Desert, the Khamsin of Egypt, and the Simoon of Kutchee and Upper Scinde, are all particularly fatal to human life; the latter especially causing sensations of suffocation and the asphyxial form of insolation. The Mistral, Bora, Tramontana, Norther, and Pampero, all cause dry pleurisy, pneumonia, rheumatism, and muscular pains, but they have little or no effect upon the nervous system.

The hot winds of Australia are dry and even afford pleasure to some constitutions. The Föhn of the North Eastern Valleys of Switzerland is also fairly healthy. In India the hot winds are rather more conducive to good health than bad, and unless the exposure to sun and the heat of the wind are very severe insolation is not likely to occur. The Loomarna, however, is said to cause "hot wind stroke." In New York and other parts of America insolation according to some observers, generally develops in the night and

(a) "Diseases of India," p. 367.

not when the person is exposed to the direct rays of the sun.

Warm days in the cool seasons of the year are especially dangerous. Moist air, absence of wind, hot winds, all favour the development. In his account of diseases prevalent in the Persian Gulf, Evatt draws attention to the terrific heat of a moist character there prevalent. Even the natives cannot endure it, and heat apoplexy assumes a deadly form. The fatal character of the heat is derived from moisture. Further inland the intense heat again assumes a terrible aspect from the hot winds drying the skin and abolishing the salutary effects of perspiration. Gordon (a) believes that in calm sultry days when the sun is obscured by a film of clouds or impalpable dust insolation is most common, since varying amounts of moisture in the air materially affect the comfort and health of man. In this country, however, it is not only the absolute, but the relative proportions of aerial moisture which influence mankind. The bodily causes arising in connection with habits or diseases of the individual are of special importance, and among these may be mentioned fatigue, over-exertion, overcrowding, bad ventilation, unsuitable dress, retained excretions, defective secretions, in fact, anything tending to debilitate or contaminate the system. Injuries to the head, malaria, scorbutic taint, venereal disease, former attacks of insolation, and alcoholism all predispose to its occurrence. Malaria, syphilis, and alcoholism not only play an important part in the etiology of insolation, but they also tend to modify and influence the subsequent history of the individual, and give rise to many symptoms which are of the utmost importance for diagnostic purposes, but of 55 cases of insanity following insolation, I found that 8 had had malaria, 5 syphilis, and 7 had been alcoholic. The latter affection especially predisposes to the indirect form of sunstroke. Sir Charles Napier, in Scinde, was fully alive to the powerful co-operative aid of alcohol in producing heat-stroke when he declared that the sun should have in his case no ally in drink. In spite of what may be thought to the contrary, I believe that the authorities who organised our recent expedition to Coomassie exercised a very wise discretion in the matter of the distribution of alcohol to the troops, and those who have not studied the subject have yet to learn that, in malarial districts there are worse things to guard against than conditions of temporary exhaustion. The coloured races seem to enjoy a comparative immunity, but when the negro removes to cities and becomes loose and irregular in his habits, and eats and drinks to excess, he becomes equally liable to sunstroke with the white race. Spirit drinking, even in moderation, powerfully aids the external causes of insolation. Even wine and beer have this effect. A full habit of body and too much animal diet favour a plethoric condition and the development of heat-stroke. Especially is this apt to occur if, after a heavy meal there is also bad ventilation.

Plethoric intemperate men suffering from fatty heart are especially predisposed.

What the relationship of syphilis to sunstroke is I am not prepared to say. Undoubtedly, syphilis (as pointed out by Hutchinson) precedes attacks of sunstroke, but the part it plays in the etiology of the affection is doubtful, and much information is yet wanted.

The special and primary syphilitic brain-lesions affecting the meninges, or vessels, or encephalic nervous substance; and spoken of as cellular hyperplasia ending in scleroses or in gummata; may undoubtedly predispose to insolation, by weakening the resistive power of the organism, and brain particularly, to the effects of heat.

The effect of the sun is more to be feared in the case of new arrivals in India, and the liability to sunstroke—

according to Bryden—is quadrupled. (a) He pointed out that, taking the standard of ten years, 1860-69 the admission rate for heat apoplexy was 4.3 per 1,000, whilst that of newly-arrived regiments, for the years 1864-69, was 16.8 per 1,000. Still more did the rate rise if a newly-arrived regiment was sent into the field at once. Thus the ratio for the new army in the field in 1858 was 55.8 per 1,000. The diminution of heat apoplexy with length of service in India was shown in the case of the newly-arrived army in 1858.

There were, in 1858, 42.9 per 1,000 affected.

"	1859,	8.7	"	"
"	1860,	6.2	"	"
"	1861,	2.2	"	"
"	1862,	1.19	"	"
"	1863,	1.09	"	"

Dr. Paynten has stated that sunstroke is never met with in the French Army in Algiers, but Duncan (b) states that this is not correct, for sunstroke does occur in Algiers. Two points are remarkable in the history of sunstroke, viz., the extreme rarity of sunstroke in mid-ocean and at great elevations. In only one of the 55 cases did the attack occur at sea, and that was in the Red Sea where, as Parkes (c) has pointed out, the proximity to land does not invalidate the rule.

At great elevations the effect of the sun's rays *per se* is not less, but even greater, than on land or at sea level, yet in both sunstroke is uncommon.

The description of the forms of sunstroke, as given by Sir Joseph Fayrer (d), is particularly graphic, and with the recognition that the affection may occur in the form of thermal, ephemeral, or ardent fever, heat syncope, heat apoplexy, and heat asphyxia, or spinal congestion, or in various degrees of intensity of these forms, with a great variety of symptoms, I will pass to the consideration of some of the most important of the nervous sequelæ.

Dr. Handfield Jones has remarked that "any man of experience in the manifold disorders of jaded and exhausted nervous systems will recognise at once how close is the resemblance between the results of tropical heat and those produced by the ordinary causes in operation among the struggling multitudes in our large towns."

The acute sequelæ to sunstroke, as ardent fever with acute delirium, remittent and intermittent fever complicated with dysenteries, hepatic inflammations and congestions are all commonly seen in India, but they have not fallen within my experience. It has been my lot, however, during the last ten years to meet with a notable number of cases in which the after-symptoms of heat stroke have been evidenced by some nervous defect or perversion essentially consisting in a functional paralysis of one or more great nerve centres.

It may be observed that the most abiding results of insolation are almost all referable to impaired functional energy of the cerebro-spinal system, and this impairment shows itself either in motor paralysis, sensory paralysis either of common or special sensation, hyper- and dysæsthesiæ of the nerves of common and special sense, in debility, and undue excitability of the emotional centres, and in similar states of the cerebral hemispheres and spinal cord.

In addition to these the extreme sensitiveness of a patient to the rays of the sun or to excessive heat ever afterwards, and the effect exercised on them by alcohol point to an unstable condition of the great vaso-motor centre in the medulla oblongata. The mental sequelæ are of extreme interest and undoubtedly an attack of insolation is often attended with meningitis or cerebral changes, which may destroy the life or intellect sooner or later, or permanently compromise the whole health or that of some important function.

(a) Medical Times and Gazette, 1857.

In many cases the sequelæ may be attributed to the injury the brain suffers during the primary attack probably from the loss of nutrition in the case of the syncopal, and from congestion in the apoplectic forms, injuries by which it may be weakened for life.

The direct effects of actual attacks of insolation are, however, by no means the most appalling, for there are many who escape such attacks whose constitution is nevertheless thoroughly ruined by sun-heat, who are rendered liable to every form of tropical malady, and who are unable to survive even slight wounds or operations.

Of the syncopal, asphyxial, and hyperpyrexial forms of insolation, the two later seem to be the most important and dangerous, and are more liable to be attended with sequelæ of a degenerative type, although even in these forms, recovery may be complete.

It is not my intention here to refer in detail to special sensory or motor affections met with apart from mental aberrations, but rather, by a more general consideration of the mental functions affected, to endeavour to embrace and establish a connection between them. In infancy, insolation is certainly a cause of accidental idiocy.

Langdon Down (a) states that he has seen a notable number of feeble-minded children who owe their disaster to sunstroke while making the passage of the Red Sea and Suez Canal *en route* from India, or from exposure in that country, and he attributes the mental decadence as originating without doubt from the actual exposure to heat. At the Royal Albert Asylum, Lancaster, I met with six cases of mental defect in children, in all of which the damage to the mental powers was undoubtedly dependent upon sunstroke, and probably the degree and nature of the defect coincided with the amount of destruction of the nerve tissue. Parents are extremely ready to attribute the idiocy of their children to an accidental fall or blow, and even in adults such causes are apt to be assigned. In any case of idiocy or imbecility which is attributed to the effects of sunstroke the existence of hereditary neurosis, the occurrence of fits, or other diseases likely to be the cause of idiocy, as well as the nature, extent, and immediate consequences of the attack, ought in great measure to aid in the formation of a diagnosis. The amount of injury to the mental powers is variable, but in all the examples I have seen the patients have been simple-minded or imbecile, rather than belonging to the lower grades of idiocy.

Sometimes the mental symptoms are found intercurrent with the sopor and coma following the shock, and they may then take the form of delirium, or excitement with hallucinations, passing into a condition very similar to that of primary dementia. As a general rule, however, although there may be some trace left of the primary injury to the brain the prognosis is more favourable in such cases than when the psychosis develops some months, or even years, after the injury.

SOME RECENT RESULTS OF ORCHOTOMY (CASTRATION)

IN CASES OF

ENLARGED PROSTATE. (b)

By C. W. MANSELL MOULLIN, M.D. OXON.,
F.R.C.S. ENG.,

Surgeon to the London Hospital; Examiner in Surgery at the University of Oxford.

THE author stated that, while it was quite true that a large number, the majority, in fact, of old men who

suffered from this complaint were enabled to lead fairly comfortable lives by passing catheters from time to time, and when cystitis set in washing out the bladder; it was equally true that many went on steadily from bad to worse, and died at last after prolonged suffering from septic absorption and inflammation of the kidneys. Drainage of the bladder in such cases is only a palliative. The formation of an artificial urethra, either supra-pubic or in the perineum, is very little better, as the patient has to wear a portable urinal; and prostatectomy is a very serious operation, not so much from the operation itself as from its being done when it is too late, in a foul and septic bladder. Orchotomy, on the other hand, offers a chance of complete and permanent relief with but little risk to life. In support of this, Mr. Mansell Moullin mentioned the conclusions at which he had arrived from the twelve cases in which he had been consulted, or on which he had operated himself. Two, both under his own care, had died; one, nine days after the operation, from fatty degeneration of the heart, the other, five days after, from rupture of the left middle cerebral artery. Two others had also died but not for six months. One of these was 82 years of age, the other was 80; and they both had experienced great relief. Two more had suffered from a very severe attack of traumatic delirium, coming on shortly after the operation and causing the greatest anxiety. They both recovered and were well at the present time. There was no evidence either that this delirium, or that the mania which had been recorded as having followed this operation, was in any way different from the traumatic delirium that not unfrequently occurs in old people after severe injuries, and may even follow the administration of an anæsthetic. As it had occurred twice after the removal of only one testicle, it could not be due to the loss of any specific power exerted by the testicles, or if any substance formed by them and excreted into the circulation. Therefore, it was not to be treated by the injection of testiculin or orchitic extract. In all the twelve cases, including that of the patient who died upon the fifth day, there was a distinct diminution in the obstruction; and although this might, so far as the early days were concerned, be explained by vascular changes, the reduction in the size of the prostate, as measured both by rectal and urethral examination, was far too complete to be accounted for in this way. In some, the prostate completely disappeared. Nor was his the result of the palliative measures that were adopted at the same time; for, wherever it was practicable these had had a thorough trial by themselves first. In one case, that of a patient, eighty years of age, the diminution in size when measured by the finger in the rectum was not very great, and voluntary control was not regained. But as a soft catheter passed easily, whereas before only a metal one or a bicoudée could be used, and that with difficulty, and as the strangury, which had resisted all previous treatment, entirely disappeared, Mr. Mansell Moullin thought the case could not be considered a failure. It was never suggested that removing an obstruction at the neck of the bladder would be able to regenerate the muscular coat, if this had been destroyed by catheterism and previous cystitis. In another case the inflammation of the bladder persisted, but this again was not the fault of the operation, for the walls contained numerous sacculi, which could not be kept empty. Mr. Mansell Moullin also mentioned one case, under the care of Mr. Manning, of Salisbury, in which unilateral orchotomy had proved a very great success; and discussed the question as to the probability of section of the vasa deferentia being followed by as good a result as removal of the testes.

(b) Abstract of Paper read before the Harveian Society, Feb. 6th, 1896.

HOSPITAL TUBERCULOSIS.

By M. TERRIER,

Physician to the Hôpital Bichat, Paris.

[FROM OUR FRENCH CORRESPONDENT.]

THE contagiousness of tuberculosis is a question of capital importance in hospital practice. In many hospitals the phthisical are freely mixed with other patients. I consider tuberculosis extremely contagious. Mathematical proof of this fact cannot be given from observation of hospital patients since the disease does not declare itself until after discharge from the hospital, but ample proof is afforded among hospital nurses and attendants at consumption hospitals.

Out of 25 male and female nurses of the Hôpital Bichat who died in the service, no less than 20 perished of tuberculosis. The contagiousness is further proved by the number of pupils and house surgeons who develop the disease; and it always manifests itself most among those who work hardest and remain longest in hospital. The laboratories have afforded striking evidence; and M. Francois-Franck records the cases of two pupils affected after experimenting with desiccated tuberculous products. There can be no doubt that the dust of apartments where tuberculous patients remain becomes charged with bacilli. Suspected cases should be isolated, and in order to determine the question, an injection of tuberculine ought to be administered. It is only in this way that the dangers of contagion in hospital can be guarded against.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, FEBRUARY 14TH, 1896.

The President, Dr. BUZZARD, in the Chair.

MR. T. W. NUNN on a case of

CHRONIC CANCER OF THE BREAST OF MORE THAN THIRTY YEARS' DURATION.

The paper was in continuation of two former papers read before the Society in 1872 and 1878 respectively, and recorded in the sixth and eleventh volume of the Transactions. The patient, S. C., residing in Camden Town, was first an out-patient at the Middlesex Hospital in June, 1862, being then 37 years of age, mother of one child. Menstruation had ceased at *æt.* 30. There was a scirrhus tumour of the right breast and a chain of enlarged glands in the axilla. The breast was removed by Mr. Nunn in September following. Four years later, 1866, pain in the muscles of the arms and in the fingers was complained of, but the pain after a short while passed off. Patient examined in 1868; no alteration for the worse. In 1878, patient examined in the presence of the clinical class, a very limited return of the disease at the upper border of the cicatrix. In 1893, over more than thirty years from the commencement of the tumour, Mr. Nunn saw the patient again, having in the mean time lost sight of her. There was an increase in the cancer deposits which were in the form of flat vein-marked plaques, and the arm was swollen. Mr. Andrew Clark took charge of the case in the out-patient cancer department of the Middlesex Hospital. The swelling of the arm having subsided, the patient ceased her visits to the Hospital. In October of the just past year, 1895, Mr. Nunn found the patient still living and energetic, and doing work as a charwoman. In December it was found that the tissues of the axilla were puckered and shrunken, the arm somewhat swollen below the elbow, the patient having, however, continued her occupation. Appended to this case is the sequel of Case 2, recorded in 1878, above alluded to. The patient died a year after the date of Mr. Nunn's paper. The post-mortem revealed secondary deposits on the lungs and liver. Drawings of the microscopical section of the breast and secondary deposits made by the

late Dr. Lyell, were now submitted to the Society. As a further illustration of chronic cancer, Mr. Nunn referred to a case of which microscopical sections of the recurrent tumour removed by him were exhibited at the Pathological Society in 1880, the original tumour having been removed seven years previously by Mr. Curling; Dr. Goodhart, the late Mr. Marcus Beck and Dr. Rickman Godlee all having determined that the case was one of cancer, and Mr. Lawson operated on a second recurrence in 1882, and the patient is, or was until lately, still living.

Mr. HOWARD MARSH recalled the case of a lady, now 71 years of age, who had had a carcinoma of the breast almost continuously for 18 years. A few weeks ago he had performed the tenth operation which she had undergone. When first operated upon there was nothing to indicate that the case would not run the ordinary course, the operation being followed by rapid recurrence. He observed that these cases served a useful purpose in view of the statement that patients in whom recurrence did not take place within three years might be regarded as cured, for they showed that such was not always the case.

SPLENECTOMY FOR RUPTURE.

Messrs. BERNARD PITTS and C. BALLANCE, brought forward two cases of splenectomy for rupture. *Case 1*, was that of a labourer, *æt.* 36, who, on October 12th, fell from a scaffold on to an iron bar which struck him across the left lower ribs. He was able to stand and walk, but was very pale. Four hours later he became profoundly collapsed, the flanks being somewhat bulged and dull, especially on the left side. The area of splenic dullness was greatly increased, not, however, extending to the spine. The same afternoon an incision was made in the middle line below the umbilicus, and on reaching the peritoneum dark blood escaped. The wound was closed with a pad, and another made four inches long from the left costal margin two inches from the middle line and parallel with it. The spleen was then found to be ruptured. It was withdrawn, ligatured and removed. No irrigation was used and the wounds were closed. He went on well until mid-day on the 14th, when the abdomen became distended and vomiting set in. On the 16th, in spite of enemata and purgatives, nothing had passed by the bowels, the patient was very thirsty but complained of no pain. The liver dullness, previously absent, had returned. He passed a copious motion on the 17th with great relief to his symptoms. By November the patient was able to get up. On October 19th, he passed 72 fluid ozs. of urine. This decreased during the next few days. Between October 26th and November 1st large quantities were passed (70 to 101 oz.). During the increased flow there was a distinct increase in the urea. On November 9th the hæmoglobin showed 43 per cent. of normal. On October 14th the temperature gradually rose to 100° 8' F. During the 15th and 16th it fell to subnormal, rising again on the 26th to 100° 8'. It continued to oscillate above and below 100° until November 5th, then it fell to 97° F. For the next three days it was normal in the morning, rising in the evening to about 100°. On November 9th, it was 101°, and on the 10th 101° 4'. The changes in the blood were well-marked, the decrease in the red cells and the increase in the white being constant. There was loss of weight during November and the early part of December. One month after the accident he had lost 42 lbs. in weight. A gradual gain in weight and an improvement in his appearance were coincident with the improvement in the relative proportion of red and white corpuscles. The treatment was at first cod-liver oil and iron, the quantity of fat in his food being simultaneously increased. On November 29th, treatment by arsenic was commenced and progress towards convalescence at once became satisfactory, the daily rise of temperature ceasing. He left the hospital on December 18th, and reported himself on January 17th, looking remarkably well. His weight then was 12st. 6lb., the same as before the accident. He was examined in February for enlarged glands. The axillary glands were found to be enlarged, and the cervical and groin glands could also be felt. No enlargement of the mesenteric glands could be made out.

Case 2.—A lad, *æt.* 10, was admitted on September 11th, at 4.30 p.m., collapsed and evidently suffering from severe shock. He was pale and the skin was clammy, respiration hurried and diaphragmatic. The abdomen was held rigidly during respiration and was acutely tender to

palpation, especially in the splenic and iliac regions. Dulness in both flanks, that in the left flank varying with position. After oscillating a good deal, operative interference became imperative, so the abdomen was opened below the umbilicus. On opening the peritoneum, much liquid blood poured out and an incision was made in the upper part of the linea semilunaris. Blood and clots welled up and on examining the spleen it was found to be ruptured. A ligature was therefore applied and the organ removed, a spleniculon being found and left in. The lad made a good recovery and left the hospital on October 4th. The injury was caused by a blow with a cricket ball five days before admission, so that his condition on admission was due to secondary hæmorrhage from the spleen.

Case 3.—A woman, æt. 45, was admitted on September 15th, having been run over by a cab. She was extremely collapsed, and complained of intense pain in the left side. A catheter was passed and a little blood and urine was withdrawn. The abdomen was opened in the middle line when much bloody fluid escaped. Another incision was then made in the upper part of the left linea semilunaris, and the spleen was found to be transversely ruptured. It was removed, the pedicle being tied with silk. About a fortnight after the operation her condition grew worse, the temperature rose to 102° every day, the pulse was rapid, and her general condition was one of extreme feebleness. There was a diminution of red cells in the blood and an increase of leucocytes. This state continued for about a fortnight, when she was put on extract of spleen and raw marrow. From this date she gradually improved, and by November 19th, she was able to walk down stairs without assistance.

Mr. SILCOCK asked whether the spleen was actually bleeding at the time of removal. In the second case, judging from the specimen, the actual wound in the spleen seemed to have been small, and removal struck one as possibly a rather heroic proceeding. It occurred to him that possibly hæmorrhage might, in some cases, be checked by means of the actual cautery. Cases of ruptured spleen often get well by themselves, for in his post-mortem experience he had met with deep cicatrices pointing to spontaneous repair of ruptures of the spleen.

Sir DYCE DUCKWORTH observed that they had not much experience of the effects of removal of the healthy spleen in the human being, though it was sometimes removed in splenic leucæmia, Hodgkin's disease, but with an almost uniformly fatal result. It would be a valuable appendix to these notes if the authors would give the subsequent history of the patients.

Mr. WALLIS had also failed to gather from the papers whether there was actual hæmorrhage at the time of operation. It was undoubtedly a valuable proceeding to open the abdomen to let out the blood and clots, but he wished to know exactly why it was deemed necessary to remove the organ. At post-mortems on patients who had succumbed after injuries of this kind, he had often seen considerable attempts at repair.

Dr. MOTT pointed out that the spleen was subject to rhythmical movements which would render it more liable to secondary hæmorrhage than certain other organs.

Mr. BALLANCE, in reply, said the patient in Case 2 was still bleeding, the rupture involving the vessels of the hilum, so that he did not see what else there was to do. He operated in Case 2 for secondary hæmorrhage from the spleen.

Mr. PITT, in reply, said the number of cases of ruptured spleen he had seen post-mortem after removal was very small compared with the fatal cases in which death had taken place as a consequence of the hæmorrhage. They had laid stress upon the fact that the spleen ought not to be lightly removed. Their experience of the removal of wandering spleen has been that no special symptoms followed the operation. In Case 3 the patient was practically moribund, and the abdomen was as full of blood as it could be. When practicable, he would prefer suture of the tear to the actual cautery. The latter, moreover, necessitated pulling the spleen out of the abdomen, and he did not think it would be a scientific or a satisfactory procedure. He promised that they would do their best to obtain the subsequent histories of these patients.

TWO CASES OF PNEUMOTHORAX IN THE COURSE OF TYPHOID FEVER, BOTH DUE TO STRAINING AT STOOL.

Dr. HALE WHITE read notes of these two cases. The

first patient, a young man, æt. 19, had an ordinary attack of typhoid fever followed by a very severe relapse. He was convalescing from this when on the 41st day while the bowels were being open after an enema he suddenly became collapsed, livid, bathed in perspiration, and almost pulseless. For some time previous to this he had all the physical signs of a little fluid at the left base, and as immediately after the attack of collapse it was found that he had all the signs of left pneumo-thorax it was concluded that, whilst straining, the pleura weakened by inflammation had ruptured. The chest was aspirated. Seven ounces of non-purulent fluid with flakes of lymph floating about in it were withdrawn. The patient improved somewhat, but died three days later. The second case was that of a boy, æt. 12, who, in the fifth week of his illness, after a severe attack of typhoid fever developed the general and local signs of a localised empyæma at the right base. An exploring needle failed to withdraw pus, but the next day he coughed some up; as the temperature did not fall, arrangements were made for the empyæma to be opened externally, but two hours before the time fixed for this, while his bowels were being opened, the boy suddenly became extremely collapsed and livid, and developed all the signs of right pneumothorax. He appeared almost dead, and was quite insensible, but oxygen inhalations seemed to keep him just going. The right chest was opened, where from the physical signs it appeared probable that fluid was present, and twelve ounces of foul pus escaped. It was done without an anæsthetic, and the boy was so far gone that he never flinched. After the operation he gradually regained consciousness, and was ultimately discharged from the hospital quite well. Here probably the localised empyæma which had burst into the lung ruptured into the general pleural cavity during straining, and hence the pneumothorax.

Dr. GOODHART read notes of the case of a man, æt. 24, who was sent to him by Dr. Qualtrough, of Holloway, on May 7, 1891. He had had a slight attack of pleurisy in 1891, and returned to work after a stay at the seaside. He said he had had flying pains about his chest for some time, and for a week previously had felt puffy in his breathing on running upstairs. When he saw him he was pallid and short of breath, with well-marked pneumothorax on the right side, the heart being displaced to the left. He went into the country for a couple of months, and returned having gained 16 lbs. in weight, and being in all respects quite well. On July 5th, 1892, he came again with a pneumothorax on the left side, which had come on suddenly. He said he had had as before, flying pains about his shoulders and chest. The heart's beat was displaced to the epigastrium and the dulness reached to the right of the sternum. As on the former occasion there was no real distress, and he considered himself quite well. He remained well during the autumn and winter, and when he saw him again there was no difference between the two sides of the chest. The interest of this case lay in the pneumothorax occurring first on one side and then on the other, in both instances apparently without adequate cause, also that the air was rapidly absorbed on both sides without giving rise to any evidence of pleuritic disturbance. The rupture of an emphysematous bleb was, he thought, the most plausible explanation of the occurrence.

Dr. HABERSON remarked that of the cases of pneumothorax at Brompton at least 90 per cent. were due to tuberculous disease, but a large majority of the remainder were due to rupture of an emphysematous bleb. Not long since he had performed a post-mortem examination in such a case. He remembered a case of recurrent pneumothorax which returned to the hospital several times, and he thought that probably in this case the condition was also due to rupture of such blebs.

Sir DYCE DUCKWORTH pointed out that the last stages of very bad cases of enteric fever were accompanied by pyæmic symptoms associated with the presence of scattered abscesses in the lungs. Possibly the rupture of these abscesses into the pleura might account for pneumothorax in such cases. He pointed out also that the presence of emphysema in young people was quite exceptional, and though emphysema in older people was common, rupture was rare.

Dr. HALE WHITE, in reply, said that he had met with cases in which the rupture of emphysematous blebs had

given rise to pneumothorax. He doubted, however, whether this was so in the first case, for there had been actual pleurisy, and the thickness of the lymph deposit would presumably tend to strengthen the pleura and so check any tendency to rupture. In the second case it was possible that Sir Dyce Duckworth's explanation might hold good, especially as there was empyæma. He remembered a fellow student who got pneumothorax while suffering from pleuro-pneumonia. He recovered and had been quite well ever since.

LIVERPOOL MEDICAL SOCIETY.

MEETING HELD THURSDAY, FEBRUARY 13TH, 1896.

The President, DR. CATON, in the Chair.

AN INQUIRY INTO CANCER.

DR. E. T. DAVIES proposed the following resolution :—
1. That in view of the inadequate information possessed by the medical profession as to the value of operative procedure in cancer, it is desirable that relevant statistics should be requested from the various hospital authorities of this city, submitted to a committee of this institution, and reported upon at a subsequent meeting.
2. That a copy of this resolution be forwarded to the secretary of each hospital and infirmary.

DR. CARTER seconded the resolution—he never advised operation in pyloric cancer, and pointed out discrepancies.

After a discussion, in which Drs. Barr and Imlach and Mr. Paul took part, the motion was put to the meeting and lost by a large majority.

THE NEW PHOTOGRAPHY.

MR. ROBERT JONES showed a photograph taken for him by Professor Oliver Lodge, in the case of a boy shot in the hand. The photograph very accurately demonstrated the position of the bullet. It was situated opposite the articulation of the os magnum with the metacarpal bone.

MR. PAUL read a paper on

THE SURGICAL TREATMENT OF GALL STONES.

Nine cases were recorded, all of which recovered. They all occurred in women, and the average duration of symptoms of gall stone before operation was nine years. In four, the gall bladder was in a fairly healthy condition. In two, it was distended to form a large tumour. In one, distended and inflamed. In one, absent, the stones being in the common duct; and in one, the ducts were dilated up into the liver, where the stone receded, and it was necessary to do cholecystotomy, for which a Murphy's button was used. Mr. Paul thought cholecystotomy for gall stone the best operation that had been introduced into surgery during recent times.

DR. MACALISTER read a paper on

THE PHYSICAL EFFECTS OF THORACIC EFFUSIONS,

in which he related the results of clinical and experimental observations having reference to the explanations of some of the physical signs of the viscerai displacements. He indicated that in acute cases the dyspnoea, immobility of the side, and diminished conduction of the breath sounds are mainly the result of the incapacitation of the diaphragm by the pressure of the fluid upon it. The cardiac displacements were shown to be due to the pressure of the accumulated liquids and the lowering of the heart to be probably related to the way in which the pleura distends, superiorly where it crosses the middle line and overlays the heart. The anatomy of the displaced organ was referred to and its relation to the lung on the healthy side. The infrequency of any palpable depression of the spleen in cases of left-sided effusions was explained by the manner in which the diaphragm becomes depressed. A marginal cul-de-sac, near its attachment to the ribs, remains, in which the head of the spleen lies, and it so remains uninfluenced by the super-incumbent pressure.

DR. ABRAM said he had listened to the paper with great interest. He could not agree with Dr. Macalister's conclusions. He agreed with Traube, Vurordt, Douglas Powell, and others, that there is a certain amount of traction by the lungs upon the mediastinum, due to the fact that they are kept in a slight amount of distension by the pull of the chest wall. This

slight distension is an indubitable fact. It followed, he thought, that the first result of an effusion into the pleura was to neutralise the traction of the corresponding lung upon the mediastinum, and to allow that exerted by the lung of the opposite side to pull the heart to the sound side. Later, actual pressure was exerted by the effusion, and the heart was now pushed over, and the diaphragm depressed. He considered diminution of Traube's space to be significant of a considerable effusion.

DR. BUCHANAN recognised the importance of Dr. Macalister's investigations, but took exception to the method of experiment, in that the introduction of fluid into an indiarubber bag placed in the pleural cavity could not perfectly represent what would take place were fluid injected into the pleural cavity itself. As the pressure under which pleural exudations accumulate is not always the same, and undeterminable, alteration in respiration must also vary in different cases; the inflammatory nature of pleuritis with exudation would certainly produce dyspnoea, in proportion to its weakness. Pleural exudation must be much slower even in what are called "rapid" cases, and in Dr. Macalister's method of injecting fluid in a comparatively sudden manner, however small, one would expect a sudden dyspnoea. Cases of extensive pleuritic exudation are not uncommon, in which dyspnoea is not at all a marked symptom. Dr. Macalister's statement that the extent of the alteration of percussion note was due to the area of lung covered by fluid, and not proportionate to the amount of fluid, being very considerable in small exudations could hardly be accepted unless the lungs were prevented from contracting by the pressure of adhesions. The loss of breath sounds on auscultation could not be principally due to the diminished action of the diaphragm irrespective of the amount of fluid, for by surrounding a normal thorax with a water cushion, the diaphragm working, all sounds are greatly diminished.

MR. THRELWALL THOMAS related an instance of displacement of the spleen into the iliac fossa, by a large thoracic effusion, empyæma. It was a case that had been sent to the Women's Hospital for "tumour," from whence she was transferred to the Royal Infirmary, under Dr. Glynn, at whose request the empyæma was opened.

DR. GLYNN, BARR, and CARTER, and MR. DAMER [HARRISON] also took part in the discussion.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD THURSDAY, JANUARY 16TH, 1896.

The President, DR. PORTER, in the Chair.

CASES.

MR. SIMEON SNELL introduced a middle-aged man with Extreme Myosis on one side, and Argyll Robertson and Ophthalmoplegia Interna on the other. There was an absence of knee-jerks and other symptoms suggestive of locomotor ataxy. A recent blow on the forehead had caused attention to be directed to the eyes, but the conditions mentioned were of old standing.

DR. KEELING showed a Dermoid Ovarian Cyst recently removed from a young woman, æt. 20, at the Jessop Hospital. The right ovary was found also diseased and removed at the same time; on section it shows commencing dermoid change.

MR. SANDHAM SYMES introduced a case of

RETENTION OF URINE.

H. L., æt. about 50, was admitted to Chesterfield Hospital suffering from retention, the urine being only passed by drops. About four years ago he was a patient suffering from an injury of perinæum and laceration of urethra. I was then able to pass a catheter and kept one in until the swelling, &c., had passed away, two small incisions were then made in perinæum. The man left the hospital quite recovered. No. 12 sound introduced without difficulty. He was told to come to hospital once a week to have an instrument passed. I believe he only came twice. On re-admission, the bladder was distended almost to umbilicus, the urine coming drop by drop. The case had been considered as one of incontinence for many months. After many efforts a soft No. 2 catheter was passed through a very tight stricture and into the bladder, passing over some rough surface. A quantity of water was

drawn off, then the instrument became blocked. A sound passed through the stricture at once proved the presence of calculus. Next day the patient was placed in lithotomy position, a staff passed to stricture and an incision made down to stricture, after cutting some bands of stricture the stone slipped back into bladder and it was necessary to do a median lithotomy.

Mr. FLETCHER gave particulars of a case of Obstruction of the Left Bronchus due to a Foreign Body. The patient, a man, *set.* 59, while at dinner was attacked by sudden dyspnoea. The foreign body, which proved to be a fragment of bone, completely obstructed the left bronchus, no air entering the left lung. The symptoms not being urgent, tracheotomy was not performed. Physical signs of consolidation appeared at the left base behind in two days, the temperature rising to 103°. On the 7th day, the patient coughed up the foreign body. After the relief of the obstruction, recovery was speedy and complete, and the patient was discharged well on the 10th day.

MEETING HELD THURSDAY, JAN. 30TH.

1. Dr. PORTER showed a case of (?) Raynaud's disease. Symmetrical gangrene had been threatened in both hands and feet. The feet, however, had recovered, and only the tips of some three fingers on each hand now seemed likely to be lost. There was no history of crises, or hæmoglobinuria.

2. Dr. ARTHUR HALL showed a case of Xanthoma. Mr. SNELL made remarks.

Mr. BARKER BARBER showed a case of out-growing tenth costal cartilage—probable cause, rickets. The PRESIDENT and Dr. LITTLEJOHN made remarks.

3. Dr. ALFRED ROBINSON read short notes on a fatal case of Chorea Gravidarum." Remarks by the President, Dr. R. Favell, Dr. Burgess, and Dr. Martin.

4. Dr. HARVEY LITTLEJOHN read a paper entitled "Six Years Notification of Infectious Diseases in Sheffield." Remarks were made by the President, Mr. Edward Barber, Dr. Samuel Mathews, Alfred Robinson, Mr. West Jones, Dr. Martin, Dr. Stokes, Mr. Harvey, Dr. Hargreaves, and Dr. Burman.

PARIS, Feb. 13th, 1896.

ARTIFICIAL SERUM.

M. LEJARS has published an interesting article which merits the attention of practitioners. He relates a case of diffused peritonitis from rupture of the intestine, followed by a flow of stercoral and purulent matter into the cavity. The condition of the patient was despaired of by the surgeons in attendance, in spite of laparotomy, which had been performed as soon after the accident as it was possible. As a last resource, and for conscience sake, a pint of artificial serum was injected into the subcutaneous tissue. The following day the patient was somewhat worse, the pulse was frequent (130) and irregular, the temperature below the normal, and black vomiting set in towards evening. The subcutaneous injections were renewed morning and evening. Twenty-four hours afterwards, the temperature rose to 102°, while the urine was rare. M. Lejars, at this stage, injected two pints of the serum into the vein of the arm. The pulse became a little stronger, and the patient expressed himself as feeling better. Two other intravenous injections were made that same day, and continued at the rate of three daily for four subsequent days. The general condition constantly improved under this treatment. After an interruption of two or three days the injections were renewed as the condition of the patient became less satisfactory, but on the ninth day, they were suppressed altogether. Consequently, in the lapse of nine days, the patient received *forty-five pints* of artificial serum! The patient was

saved in spite of an accident which might have seriously complicated the situation. On the tenth day, through an effort at coughing, the line of sutures burst, and the mass of intestines bulged forward through the wound, covered only by the peritoneum.

Two other cases were related by M. Lejars witnessing in favour of intravenous injections of artificial serum, and from which he drew the following conclusions:—Intravenous injections of aseptic serum at blood temperature and in massive doses (two pints three times daily) are inoffensive; these injections are capable of bringing about most unhopd for cures in certain affections, especially those interesting the peritoneum; the injections seem to act by provoking large evacuations of the toxins of the blood, through the kidneys.

The author terminates his article by giving a description of the *modus faciendi*. "Our method of operating is very simple. We use a glass recipient properly sterilised, and a glass cannula with a fine point; the vein is dissected through a small incision tied and opened with every antiseptic precaution above the ligature, and the cannula introduced, care being taken not to let in a bubble of air. By raising the recipient the liquid enters by its own weight; a certain thrill felt by the finger indicates that the solution is penetrating. At the end of the operation the vein is tied above the wound and the skin brought together by two sutures. At the second injection a segment immediately superior of the same vein is opened or one of the neighbouring veins. In proceeding thus by segments from below upwards from the bend of the elbow to the shoulder, on the superficial veins, quite a series of injections can be made, clots being entirely exceptional. In the case above related in detail more than twenty injections had been made in both arms.

"It might be possible to pierce the vessel directly with the point of the canula, if it were standing out in bold relief, but it must be remembered that the cases where these injections are useful the veins are frequently flaccid. Out of fifty intravenous injections we never observed the slightest accident, nor have we remarked that the operation was painful. Sometimes, however, we observed a little dyspnoea at the end of the injection. The patients feel the liquid penetrating they experience, at first, an irritation of the tongue and mouth, then a difficulty in breathing and finally a sharp abdominal pain of short duration, all these sensations proving that the liquid was being rapidly diffused. As to the liquid, the useful formula of Prof. Hayem:—

Chloride of sodium (pure), 5j;
Sulphate of soda, ʒij;
Distilled water, 1½ pints.

"The question of intravenous injections as applied to certain diseases is still on its trial, but in my opinion we have here a therapeutic method of considerable value in the great struggle with death."

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, Feb. 14th.

At the last meeting of the Medical Society Hr. Laevin showed a case of

CONGENITAL SYNOPHTHALMIA.

The child was the sixth from a woman who had given birth to five healthy children. It was born alive at the

eight month, the labour being completed naturally, but only lived a minute. There was an abnormality of the anterior cerebrum. In the median line of the frontal bone, where the bridge of the nose comes, was a cavity in which the two eyes the development of which was arrested, could be distinguished. They presented the appearance of the so-called cyclops or synophthalmia. The two eyes were separated from each other about half a centimetre. The cavity was surrounded by two folds that could be recognised as the later eyelids. There was also hydrocephalus and also dropsy of the amnion on the part of the mother.

Hr. Rothmann showed a preparation of

TWISTING OF THE COLON,

taken from a young woman of 22. The father had suffered from obstinate constipation. The patient also suffered from constipation that gradually became worse. In the summer of 1894 she had an attack that lasted six days, with great sacral pain. Relief was obtained by means of repeated enemata of oil and water. In December of the same year she had a similar attack. The speaker concluded that the case was one of opoerostasis from stenosis of the large intestine. With careful dieting the patient got through another year fairly well, but with occasional attacks. The last attack was in December, 1895. On January 20th the speaker was called to her, as the bowels had not been opened for eight days, and all attempts to effect an evacuation failed. Vomiting came on, and on the third day Dr. Körte was called in. As the patient had then to be removed to Hr. Körte's klinik, opium was given, and the operation was performed the same day. First of all the cæcum was opened, to give exit to the collected fæces. The narrowed part was next sought for. During the night the patient became collapsed, and died the following day. Even at the operation a much distended blue-red coloured piece of large intestine appeared at the wound opening. At the autopsy the left half of the abdomen was found to be filled with blueish-red folds of large intestine, whilst the right half was occupied by small intestine. The narrowing was not at the cæcum, but at the right flexure of the colon, and was caused by twisting of the bowel. From this point was a part distended to the size of a distended stomach, and below this another point, the axis of which was also twisted, and below this normal rectum. It was concluded that there was congenital lengthening of the meso-colon that allowed of rotation, and that a subsequent attack of peritonitis had permitted adhesions to be formed in such a way that the bowel could not return to the normal direction.

Hr. Aronsohn showed

PHTHISICAL LUNGS FROM A GOAT.

This was the first time successful inoculation of a goat with tubercle bacilli had ever been performed. The animal had been under observation a long time, and had already been the object of experiment. In May, 1893, it had injected 2 ccm. of tuberculine, and these doses were gradually increased. In October of the same year, 30 ccm. of a pure preparation of tubercle bacilli were injected into the test, and in the following month, other injections were made in quantities of 45 to 150 ccm. In May, 1895, 200 ccm. were given. The animal lost weight, but otherwise it seemed well, with the exception of an evening rise of temperature. In July, 1895, a large quantity of blood was withdrawn, and this was followed by rapid changes; a sort of hectic set in. The animal emaciated, and in six weeks after the

venesection it died. The rapid course was a proof of the influence of debilitating influences in the origination of phthisis. Hr. Virchow remarked that no doubt had ever been thrown as to the tubercular nature of phthisis, but only the observation had been made that there were other forms of the disease which might be bacillary without being tuberculous.

Hr. Aronsohn said that he only had an earlier expression of Liebreich's in his mind to the effect that the essence of phthisis should not be sought in the tuberculosis, but in other accidents. He did not doubt that phthisis arose in other ways, he had only attempted to prove that typical phthisis might be set up by subcutaneous injection of tubercle bacilli.

A CASE OF MORBUS BASEDOWII CURED.

Hr. Liley, in connection with the opinions of Herren Senator, Ewald, and Mendel, expressed at the last meeting as to the uselessness of thyroidine treatment in Basedow's disease, brought forward a case that showed the contrary. The patient was first treated in Senator's Klinik with arsenic, but without result. The patient got worse from week to week although she was sent away into the country. On coming home again she showed all the symptoms of the disease, Graefe's sign, exophthalmus, trembling of the hands, &c., and she could only drag herself up the steps with difficulty. A lady made her a present of three boxes of German thyroidine tablets, of which she took six tablets a day. Although attending the poliklinik occasionally, she continued taking the tablets on her own responsibility, and at the present time, after about four months of the treatment, she could be pronounced nearly well. The circumference of the neck was reduced from 35 to 33 ctm., the cardiac murmur had disappeared, and scarcely any trembling remained. It had to be looked for carefully before it could be noticed. The subjective condition was good.

Hr. Senator said his observations had been made with the English tablets.

Hr. Ewald remarked that Hr. Silex's experience did not stand alone. A number of such cases had been described, especially in English literature. The majority of the observations were, however, unfavourable. He himself had seen no good result. In his case related at the last meeting the symptoms returned in an exaggerated form, and the thyroidine was no longer of any use.

Austria

[FROM OUR OWN CORRESPONDENT.]

Vienna, Feb. 14th, 1896.

BLOODLESS TREATMENT OF CONGENITAL LUXATION.

ADOLF LORENS brought forward a few of his cases for exhibition in the Gesellschaft this week. From his experience of more than 200 cases, upon which he has operated in recent years, we may conclude that congenital dislocation of the hip-joint is not a rare affection.

The deformity in all cases has been corrected and replaced by making an opening over the joint, clearing away obstructions, and re-establishing natural movement in the acetabulum.

After much thought and careful observation of the cases operated on he resolved to alter this treatment in 1895, and since that time has operated on 13 cases with perfect success and without any cutting. He qualifies the new treatment by affirming that it is unsuitable in

cases where the child has been allowed to grow up with it to the seventh or eighth year, as the rudimentary acetabulum has by this time become almost obliterated. In young children, by careful manipulation the head of the femur can be readily made to return to the fossa, with a sharp sound, and will remain without any external pressure.

The order of his treatment may be concisely arranged in four phases or stages: (a) *Reduction*.—The returning of the head of the femur, which is usually fixed above the fossa or acetabular depression. (b) *Reposition*.—The exact planting of the head in the rudimentary acetabulum. (c) *Formation*.—The developing by absorption of the acetabulum. (d) and lastly, *Restitution*.—The movement in the joint by the muscular apparatus.

In the operation of opening the joint by incision the order is slightly different, viz., reduction, formation of cotyloid cavity, reposition and restitution; but the object in view is exactly the same in both. In the bloodless operation the reduction and reposition may be taken together. The limb is extended, by hand or screw, slowly increasing the force, while the head of the bone is manipulated by the operator till he is satisfied that the position of the trochanter and head of the femur are in the normal relative situation to the epina superior anterior, when pressure is applied inwards, driving the head of the bone into the socket. To secure the latter result, *ad maximum*, the limb must be moved to a right angle by abducting the leg, which is a very essential part of the proceeding. If the operation be conducted slowly with the rolling outwards and bending the leg back an acoustic phenomena will occur that cannot be mistaken when the head of the bone slips over the lip of the acetabulum, which will signalise the reduction. After this the limb must be kept in the abducted position with flexion at the knee-joint, or the automatic action of the surrounding muscle will tend to re-dislocate the bone. This is also necessary in the incised operation, but is easier managed in the bloodless treatment. After accomplishing the reposition we must wait patiently, often for years, before the absorption is complete or the cotyloid cavity deep enough to safely retain the head of the bone, but during this period much may be done to hasten the operation when the patient is healthy, by arranging it in such a manner that the weight of the body may press the head well into the acetabulum.

After three or four months it will be found that the leg has lengthened three or four centimetres, and that an instrument is almost unnecessary, as the gluteal muscles are the principal sentinels in these cases.

The first case that he exhibited was four years old; she was anaesthetised on September 28th, 1895, the hip reduced, abducted and fixed. On December 11th, 1895, the abduction was reduced three centimetres, i.e., the healthy leg required a sole of three centimetres to equalise the lengths. This was fixed a second time, and not released till January, 1896. During the whole period the weight of the child was allowed to fall on the joint, and only during the first fourteen days was the child prevented from walking. After the removal of the apparatus, the child still wore the sole below the sound foot, but after a course of massage and gymnastics, the child now walks without anything, and without any trace of the former defect.

The second case was a child of three years; was anaesthetised, and first fixed on July 5th, 1895. This treatment was continued with one change till January 20th, 1896, lasting six months. At the present time, the child can walk without any apparatus excepting a sole of three

centimetres below the sound foot. The history is much the same as in the preceding case.

The third case was a boy of three years, who was similarly treated on April 30th, 1895, but was kept stationary for eight weeks. Three months after, the apparatus was removed; massage, &c., applied, and perfect recovery ensued.

Another case of a girl, four years of age, who, after seven months' treatment, was similarly restored.

Twenty-five other cases were shown, *seriatim*, ranging from one to three years of age, in whom no one could tell from their gait that there had been anything wrong.

BENEDIK'S JUBILEE.

During the past week Prof. Benedik has been the object of admiration and homage by all the learned bodies in Vienna. It is now forty years since he appeared in the literary world as a writer.

The Operating Theatres.

ST. THOMAS'S HOSPITAL.

ABDOMINAL SECTION FOR INTUSSUSCEPTION. — Mr. ANDERSON operated on a case of intussusception by abdominal section. The patient, a little boy, *æt.* 3, was admitted with symptoms of obstruction of twelve hours' duration. The usual symptoms of intussusception were present. An elongated tumour could be felt in the position of the ascending colon, extending into the adjacent portion of the transverse colon. The child was in considerable distress, and vomited after admission. An attempt was made to reduce the intussusception by rectal injection, but without success; the tumour was considerably reduced in size, but could still be felt, and the symptoms of obstruction remained unchanged. Mr. Anderson opened the abdomen by an incision in the right linea semilunaris. The large intestine was exposed, and in drawing it into the wound the intussusception, which was about three inches in length, was reduced without further manipulation. There was considerable thickening of the coats of the intussuscepted portion of the ileum, but the condition of the gut was otherwise favourable. The wound was then closed. Mr. Anderson remarked that abdominal section for intussusception had rarely been successful, but this depended upon the unfavourable conditions antecedent to operation, and there was little doubt that if the cases were brought before the surgeon at an early period the result would be in the majority of instances good. He drew attention to the readiness with which the invagination was righted in the present case because no adhesions had taken place. He disapproved of the preliminary use of injections, because although occasionally successful they placed the surgeon at a disadvantage when, as was usually the case, they failed; they not only caused loss of valuable time but the severe distension of the large intestine was liable to leave it in a paralytic condition that was in itself prejudicial to the patient's recovery. The abdominal section itself in a recent case was probably attended with a minimum of danger; less danger than the blind use of injections. He had, a few weeks previously, performed the operation upon a child of a few weeks old, and although the necessary manipulation was somewhat tedious owing to the long period that had elapsed before the child was brought to the hospital, a considerable improvement took place after the reduction, all signs of obstruction disappeared and the

patient lived until the fourth day when he sank from asthenia.

It is satisfactory to state that a week after the operation just described the child was doing well, the intestinal functions being restored.

MIDDLESEX HOSPITAL.

UTERINE MYOMA COMPLICATED BY AN OVARIAN TUMOUR.

—Dr. WILLIAM DUNCAN operated on a woman, *æt.* 35, who was admitted with a solid central tumour reaching nearly up to the umbilicus, and which she had noticed for some years. In addition, there was a cystic swelling occupying the left side and extending up under the ribs. This was diagnosed to be an ovarian tumour. Per vaginam, the solid growth was found to be connected with the uterus, and filling up the right side of the pelvis. On opening the abdomen in order to reach the cyst, the incision had to be extended half an inch above the umbilicus. The swelling was found to be ovarian, pushed up by a large fibroid occupying the lower abdomen. The cyst was tapped, drawn out of the abdominal cavity, the pedicle transfixed, and the tumour removed in the usual way. Dr. Duncan then proceeded to remove the uterine growth. The uterine artery on the left side could be felt pulsating, but owing to the myoma burrowing in between the layers of the right broad ligament, the artery on that side could not be felt. He next passed an elastic ligature tightly round the lower end of the tumour, fixing it by means of a clamp forceps. The large myoma which was seen to spring from the right side of the uterus was then cut across, the peritoneum dissected off its surface, and it was finally enucleated from its attachments both to the uterus and in the broad ligament. In separating it from the uterus the uterine cavity was fortunately not opened. The elastic ligature was next removed, upon which very severe hæmorrhage took place from numerous vessels, both arterial and venous, which were seen to be spouting from the wall of the cavity left in the broad ligament after the removal of the tumour; this cavity was about the size of a small foetal head. The vessels were clamped with forceps and each one tied separately until all bleeding was arrested. The edges of the raw surface on the right side of the uterus were carefully brought together with silk, as were also the edges of the layers of the broad ligament, with the exception of a small opening into which a glass drainage tube was passed to the bottom of the cavity. The abdominal incision was then brought together in the usual manner. The operation lasted nearly three hours, but the patient's condition was very good at its completion. Dr. Duncan remarked before operating that the cystic tumour was most probably ovarian, although the whole condition felt on abdominal palpation might be accounted for by a uterine fibroid undergoing cystic degeneration. After the operation, he pointed out the great difficulties attaching to the removal of a uterine myoma which burrows between the layers of the broad ligament, and he said that the operation would have lasted even longer than three hours had he not been able to have the valuable and kind help of his colleague, Mr. Henry Morris. The elastic ligature completely controlled all bleeding until it was removed. He thought that in another similar case, instead of draining through the abdominal wound, he would carefully and completely shut off the cavity in the broad ligament from the general peritoneal cavity and make an opening into the vagina, through which he could pass a drainage tube, and thus get more complete drainage.

At the end of eleven days, the patient's condition is satisfactory, but as she is a very stout woman, there is suppuration in the abdominal wall, especially where the drainage tube was kept in for thirty-six hours.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, FEBRUARY 19, 1896.

PHARMACOLOGY AT THE LONDON CONJOINT BOARD.

THE recent action of the London Conjoint Examining Board in discarding pharmacology from the subjects of examination calls for some explanation in view of the importance of the subject thus summarily dismissed. In January, 1882, the Board issued a synopsis of pharmacology, setting forth the scope of the examination in that subject, and this synopsis was reissued in November last, without alteration or modification. In conformity with the policy enunciated in this synopsis, the lecturers at the various London and Provincial schools abandoned the teaching of *materia medica*, pharmacy being in most instances relegated to the hospital dispenser, confining their attention to pharmacology and therapeutics. So far, all was plain sailing, and we do not remember to have heard any objections to this arrangement for conveying to the students an elementary knowledge of a highly important branch of medical education. A short time ago, however, just when an examination was imminent, an agitation was

set on foot, in which, as far as we can gather, Drs. West, Norman Moore, Fowler, and Thorne-Thorne, took a principal part, against the subject of pharmacology, and at the meeting of the College which took place on the 13th inst., a resolution was passed abolishing pharmacology as a subject to be taught and examined in. *Materia medica* is already done away with, so that the student of the future will only be called upon to occupy himself with pharmacy. Now, pharmacy is undoubtedly a subsidiary branch of medical knowledge of great practical importance, indeed, we should welcome more stringent requirements in this direction in order to prevent the writers of prescriptions from making themselves, as is at present so frequently the case, the laughing stock of dispensers. But surely a knowledge of pharmacology, which is the science of the physiological action of drugs, is a subject in which the medical man ought to be peculiarly proficient. Without it he can only follow the beaten track, without it prescribing becomes a matter of routine, and further progress of knowledge in the direction of the application of drugs for the relief of disease becomes impossible. Pharmacology constitutes the chief basis for the application of remedies in disease, and may, indeed, be regarded as the connecting link between *materia medica* and the art of pharmacy. The *rationale* of the employment of such drugs as it is customary to exhibit in particular conditions or to meet special indications must necessarily escape the practitioner who has never been taught the action on the healthy organism of the drugs he employs, and further developments in this direction become impossible. Are we to take this retrograde step, for such it appears to us to be, as a manifestation of the prevailing spirit of therapeutical scepticism which has come over the authorities who control medical education? Or is it that those who are responsible for the change think that the advent of what has been styled organic therapeutics, by the aid of serums and juices, renders a knowledge of the properties of the old-fashioned remedies completely unnecessary. We are, of course, not in possession of the arguments on the strength of which this sweeping alteration has been brought about. The curriculum may be unduly crammed, and it may be that it exacts more than the most diligent student can compass within the allotted time. But even so one would have thought that pharmacology, which is to therapeutics what a knowledge of anatomy is to surgery, would at any rate have retained the honoured place which it has occupied up to the present time. We are strongly of opinion that the subject ought to find a place somewhere in any and every scheme of medical education, and we are fain to hope that it may be reinstated somewhere in the curriculum without waiting for generations of students to be foisted on the public ignorant of the very elements of their art as practitioners of medicine. Possibly, the Education Committee of the General Medical Council may hold that the matter is one calling for their consideration, indeed, we are unable to reconcile the action of the College with the requirements of the Council in this respect.

MAGISTRATES AND THE MEDICAL ACTS.

SINCE the successful prosecution by the Medical Defence Union of the quack named Ferdinand who sought to pose as a qualified medical man by the use of the titles M.D., U.S.A., one would have thought that the precedent then established would have been sufficient to enable any magistrate to arrive at a right judgment upon a similar case which happened to come before him. Apparently, however, this is not the fact. Either certain magistrates do not read the newspapers or they do not profit by the information which the latter contains. The following is a case in point:—At the Cardiff Police Court, last week, a person styling himself "Dr. Bridgwater, M.D., U.S.A.," was summoned under the Medical Acts for having wilfully and falsely represented himself to be a doctor of medicine. The chief witness against the defendant was Dr. Morris Evans, a retired medical practitioner who had received a circular of a nature which clearly showed that Bridgwater intended the public to believe that he was a medical man. The solicitor for the prosecution rightly contended that the letters "U.S.A." did not exonerate the defendant from liability under the Acts. Despite, however, the clear exposition of the law of the case by Mr. Sheil in the Ferdinand prosecution, the magistrate held that the defendant had not used a description implying that he was a registered practitioner of the United Kingdom. He therefore dismissed the summons. In the meagre report which has reached us of this case it does not appear that the successful prosecution of Ferdinand for the same offence was ever referred to. If, however, no reference was made to it, there is no denying the fact that the prosecution in the present instance was sadly mismanaged. But in the absence of evidence upon this material point it is impossible to discuss this matter further. With regard to the magistrate's decision it will be observed that he seemed to think that any medical title could be assumed, without offence against the law, provided that the person so doing did nothing to imply that he was registered under the Medical Acts. Clearly this is a most dangerous and erroneous interpretation to have conceived of the clause in the Act of 1858, which deals with the assumption of medical titles. The clause in question may here be quoted: "Any person who shall wilfully and falsely pretend to be or take or use the Name or Title of a Physician, Doctor of Medicine, Licentiate in Medicine and Surgery, Bachelor of Medicine, Surgeon, General Practitioner or Apothecary, or any Name, Title, addition or description implying that he is registered under this Act, or that he is recognised by law as a Physician, or Surgeon, or Licentiate in Medicine and Surgery, or a Practitioner in Medicine, or an Apothecary, shall upon a summary conviction for any such offence, pay a sum not exceeding twenty pounds." Could anything be clearer than this clause? It specifically lays down that any person who falsely pretends that he is recognised by law as a physician or surgeon is liable under the Act, and this is precisely the offence which a quack commits when he assumes the title M.D., U.S.A. He

poses, in other words, before the public as a medical man. By virtue of his titles he is believed to be a medical man "recognised by the law." It is not necessary in these cases for evidence to be produced showing that the quack did anything to imply that he was registered under the Act. The public knows little or nothing about the Medical Register. The only thing to which they pay any heed is whether a person claiming to be a doctor is one or not, and when they find that he calls himself a doctor, and attaches to his name "M.D., U.S.A." they naturally arrive at the conclusion that he is a medical man. At this point it will be seen how important it is for the law to step in and protect the public in such a matter. But, obviously, if the magistrates who are paid to administer the law will not take the trouble to inform themselves in respect to the proper legal aspect of these cases, the sooner that something is done to remind them of their duty the better. It is to be trusted that "Dr. Bridgwater, M.D., U.S.A.," will not be left for long in undisturbed possession of his titles, but that the case will be taken up by the Medical Defence Union, whose officers have proved themselves in many instances to be quite *au fait* in demonstrating to magistrates the true meaning of certain clauses in the Medical Acts.

SHEFFIELD, AND ITS MEDICAL OFFICER OF HEALTH.

PUBLIC health work does not seem to be very highly esteemed in Sheffield. The majority in the City Council do not show any very marked desire to retain the services of a man with ripening experience in the work of his department. In Dr. Harvey Littlejohn, they have an excellent public servant; a man who has discharged the onerous duties of his position with a fearless honesty of purpose, tact, and energy, and has given complete satisfaction to the Members of the Health Committee, under whose oversight his work more immediately lies. He has won the confidence and cordial co-operation of the medical profession in the city, and the clauses of the Notification Act have been carried out without the slightest friction. Moreover, he has given the town five years good hard work. What has been his reward? On Wednesday, February 12th, at a meeting of the City Council, a proposition was brought forward by the Health Committee unanimously, that Dr. Littlejohn's salary should increase each year by the sum of £50, until it attained a maximum of £750 a year. From the members of his Committee he received the highest encomiums upon his work. It was pointed out that places which are certainly not of greater importance (though it cannot be denied that they are possessed of a more enlightened appreciation of their responsibilities, and of good work) than Sheffield, pay their Medical Officers of Health much better. Brighton gives £800, Hull £700, Bristol £800, Newcastle-on-Tyne £750, Nottingham £600, and so forth. It was pointed out also that during the five years Dr. Littlejohn has been in Sheffield, the work of his department has greatly increased. But all to no purpose. There was no grand scheme before the Council dealing with the expenditure

of thousands, and with a possible flavour of party spirit about it. Instead there was a mean pettifogging spirit of economy in the air, which evidently affected the minds of men who ought to have been above it. They were bent on proving to the ratepayers that they had their interests at heart, and meant to guard their pockets. They set no store upon the possession of a good man, with an excellent record of service, and a ripening experience of the work with a thorough knowledge of the details of the requirements of his department. No! an infinitesimal saving of a fraction of a farthing was of far greater importance than such considerations. A Mr. Muir Wilson proposed, and a Mr. Wardley seconded an amendment that the advance sought for should be refused, and this, to the disgrace of the Council, was carried by a vote of 29 to 21. Of the aldermen only 3 voted against, as compared with 12 who voted for the advance. Dr. Littlejohn may congratulate himself upon the support he received from the men of enlightenment and position on the Council. The majority have very little to congratulate themselves upon; they certainly will not be regarded with any feelings of admiration by those who know that good work is worth paying for, and not to be dealt with in a spirit of mean economy. Men of ability must, in future, not regard Sheffield as a place where talent is likely to be appreciated and rewarded; they must look upon it as a place in which experience may be acquired, but, when acquired, they must go elsewhere to have it appreciated at its proper value. The minds of the majority of the City Council of Sheffield are too small to allow of their doing so. They think that a hard and fast income of £500 a year is all that a first-class man should receive for watching over the health interests of a population which, at the last census, numbered 330,000, and which, during the past five years, has increased by another 25,000 people; truly they rate the position and importance of their city and its dignity at a low figure, and cause it to take a back place among the towns which do appreciate public health work at its proper value. We trust that the members of the profession in Sheffield will take an early opportunity of expressing their disapproval of Dr. Littlejohn's treatment by the Council, and their appreciation of the work that he has done for Sheffield.

Notes on Current Topics.

Pharmaceutical Controversies.

A QUESTION has recently been raised by an apprentice serving in the establishment of Grattan and Co., of Belfast, who asked that his certificate of such service should be accepted by the Pharmaceutical Society as qualification for its examination. The Society refused on the ground that Grattan and Co. were not registered pharmacists, but only a general trading firm with a pharmaceutical department. The apprentice applied to the Queen's Bench for a *mandamus* to compel the Society to admit him to examination, but he was defeated because the Court held that a limited company is not a "pharmaceutical chemist,"

and, therefore, cannot give valid certificates. But the Court thought that the apprentice had a legitimate grievance, and "recommended him to mercy" of the Society. Forthwith nine other apprentices, similarly placed, applied for recognition, and after grave debate the Council of the Society decided that it is questionable whether they have any legal power to admit even one apprentice under such circumstances, and they adjourned the question to allow of a law opinion being taken. The decision thus given that a company is not a "person" has, however, resulted in the defeat of the Society upon a much more important dispute. The Society sued a limited company at Lisburn for compounding prescriptions through the agency of a duly qualified pharmacist. The facts were admitted and it was also admitted that an unqualified person would be liable to penalty for compounding, but here again the Court held that a company is not a "person" and is, therefore, not touched by the law at all, and is not liable to either prosecution or penalty. The effect of this decision, if it is upheld in the Court of Appeal and in the House of Lords (where, we believe, the Society intends to take it) will be to throw open the practice of pharmacy to any or every person who chooses to call himself a company and to register himself as such. This ruse has already been adopted to a considerable extent in England, and if the appeal fails, there will be no remedy for the abuse save an alteration in the Act of Parliament.

The Direct Representation Contest in Ireland on the General Medical Council.

THE result of the preliminary vote instituted by the Cork Society for the purpose of selecting a candidate to carry the flag of the provincial lists was announced on the 11th inst., showing that Dr. Cuming, of Belfast, had polled 376 votes; Dr. MacDonnell, of Dundalk, 232; and Dr. Greene, of Ferns, 77. The result of this vote has been the retirement of Drs. MacDonnell and Greene, and the contest now lies between Drs. Jacob, of Dublin, Cuming, of Belfast, and Thomson, of Dublin. It is impossible to draw any just conclusion from this vote considering that, out of a total constituency of about 2,700, only 685 voted on this occasion. The only fact calling for observation is that Dr. Cumings' total vote exceeds in number his first published list of supporters by only 33 votes, these representing apparently all the additional supporters whom he has been able to gather together since the issue of that list. The nomination papers of the three candidates were lodged at the Branch Council's Office on the 15th inst., and the voting papers will go out on or about the 20th. The poll will continue until the 27th, and the result will be declared about the 3rd of March. The trial of strength lies practically between Dublin, represented by Mr. Thomson, with some country following; Belfast, represented by Dr. Cuming, with a strong support from the two adjoining counties; and Dr. Jacob, who depends upon the Poor-law men and other country practitioners, but has also a fair share of Dublin support.

The Medical Staff Corps and Drilling.

THE *Broad Arrow* never loses the opportunity of finding fault with or deprecating the Medical Department of the Army. The latest "grievances" are that there is far too much "soldiering" in the Medical Staff Corps, that string bands are by no means necessary luxuries, and that the hospital staff at Aldershot might easily exist without a band. Our kindly disposed contemporary also adds, "that any day at Aldershot men of the Army Medical Staff Corps may be seen learning manual exercise, or sometimes amusing themselves and the doctors who command them, by acquiring proficiency at battalion drill. All this is utter nonsense. In savage countries it is no doubt desirable that the hospital orderlies, &c., should be armed in order to give them the means of protecting their lives in cases of emergency. But if our medical people take rifles into the field in a European War, how can they claim to be non-combatants? All the ordinary drill that the Medical Staff Corps requires is the power of forming fours in order to march to church. Rifles are useless to them and so is everything of a military character which is not strictly connected with the discharge of hospital or ambulance duties." What petty jealousy the above remarks display. We wonder how long it will continue to be fashionable among army officers to follow the lead of the late Commander-in-Chief, and sneer at everything that the Army Medical Department does which tends to add to its efficiency.

Influenza in India.

INFLUENZA, according to a recent issue of the *Indian Daily News*, is raging throughout the Upper Punjab. Rawalpindi, Abbottabad, Nowahera and Peshawur have had their full tale of sufferers. In Peshawur especially there have been few houses in the cantonment exempt from the scourge, in either a mild or severe form. The great want of rain and the consequent prevalence of dust may have increased the virulence, but there is no doubt, that the residents have been visited by an epidemic of the severest type affecting all classes. Chest diseases also are very much to the fore, and the medical staff is having a hard time of it. The year has certainly not begun well from a health point of view, for all the hospitals are pretty full.

"No English Wanted."

THE official announcement to the effect that the English language will be excluded from the proceedings of the Twelfth International Medical Congress to be held in Moscow in August, 1897, has naturally excited a good deal of irritation both in this country and America. The announcement, quoted in full, is as follows: "French is recognised as the official language of the Congress in all its international relations. At the general meetings the addresses may be delivered in other European languages. Papers may be read and discussed in the meetings of the section in French, German, or Russian." It is of course true that most men of any scientific note are quite *au fait* in the French and German languages. But it is not only for scientific men that these congresses are held. These

reunions take place just as much for one section of the medical community as for the other, just as much for the general practitioner as for the scientific consultant. To exclude, therefore, the most important language in the world from the Congress, simply means that those who speak it, and are not sufficiently acquainted with the official languages, will not attend. Perhaps, however, there may be many reasons for the decision which has been arrived at in this regard. The Roman Congress, as is well remembered, was a complete fiasco in many respects owing to the unwieldy attendance; it may be, therefore, that the Russian authorities have seen that one of the sources of overcrowding will be eliminated if no facilities are provided for the attendance of English-speaking practitioners.

Medical Journalism in Australia.

At a special meeting of the Medical Society of Victoria, held in December last, it was decided to amalgamate the *Australian Medical Journal* with the *Inter-colonial Quarterly Journal of Medicine and Surgery* under a new title. Thus our old and well conducted contemporary, the *Australian Medical Journal*, will, as such, cease to appear. However, regretful as this act may be, there is nevertheless this to be said greatly in its favour, namely, that it has done a good work in its time. Founded as long ago as the year 1856, the journal had become one of the oldest of the monthly medical periodicals in existence. It was started by and has always been the organ of the Medical Society of Victoria. In an editorial in the issue for December last the circumstances are explained under which the change to be carried out has been brought about. One important factor was the commercial depression through which the colonies have been passing. Another was the decision of the Australian branches of the British Medical Association to supply their members with the *Australian Medical Gazette* as well as with the organ of the Association. Thus the competition became too great for the existence of an independent journal, and this has led to the amalgamation scheme to which reference has been made.

Alcoholism in Children.

It is well known that cases of alcoholism and dipsomania are met with in children. The tendency, in some cases, is hereditary; often it is the result of some psychical disturbance. Many cases are due to the ignorance of mothers who quiet their infants, even while at the breast, with wine or spirits. The pernicious habit of parents taking their children into public houses, and there allowing them to share the drinks, is self evident. Another matter is that there is always a risk in ordering alcohol for children. Moreover, where there is a history of alcoholism in a child's parentage, the safer plan would be to avoid the stimulant entirely. Dipsomania, generally hereditary, occurs both in boys and in girls, in the latter about the time of the first menstruation. Delirium tremens has been seen at five years of age; and cirrhosis of the liver, with a definite history of abuse of alcohol, at three years and a half. Again, children who have suffered

from the effects of alcohol, are especially liable to epilepsy, hysteria, insanity, and so forth. Of course, the prognosis in such cases is bad. All these facts are worthy of careful consideration when the question of administering alcohol to children comes before the medical practitioner. The probability is that the confirmed drunkenness in many women has taken its origin from the alcohol which has been given them in the early days of their childhood, when they were regarded as "delicate," and unable, without some stimulant, to "keep up their strength."

An Opening Ceremony.

THE Cardiff Medical Society held its annual meeting last week, and at the invitation of the Society, many members of the South Wales Branch of the British Medical Association attended the proceedings. Mr. Frederick Treves was present and read a paper on "The Present Position of Abdominal Surgery." Subsequently, the members of the Society and their guests adjourned to the newly acquired meeting rooms. Whereupon, quoting from the *Western Mail*, "Dr. Treves was called upon to perform the opening ceremony, which he did in a few words, remarking that he was familiar in some degree with the opening of chambers, but he found the opening of the abdomen not nearly so difficult a feat as the opening of a Medical Society's rooms."

The Army Medical Report.

LAST week the report of the Army Medical Department for 1894 was issued from the War Office. The report deals exhaustively with the health of the forces in all parts of the Empire, and the Director-General (Surgeon Major-General Sir W. A. Mackinnon) states that the statistics from the United Kingdom compare favourably with those of 1893. In the Colonies the general health shows improvement, and in Egypt the improvement was marked. In Bengal there was an increased rate of sickness, a severe outbreak of cholera occurring, with a very high percentage of mortality. At Lucknow 144 cases occurred, ninety-seven of which proved fatal; and on investigation the opinion was formed that the sand in filter-beds attached to wells was contaminated with the cholera microbe. The Madras statistics showed increased sickness as compared with 1893, and in Bombay also the comparison of 1894 with the preceding year and the previous ten years was somewhat unfavourable. At home there were eleven cases of small-pox, the highest recorded number since 1888; the other eruptive fevers had decreased, also enteric fever and influenza. But how is it that the Report for 1894 appears two years late?

At the Queen's Hospital, Birmingham, last week, a successful operation was performed with the aid of the Röntgen photograph. A fortnight ago a woman ran a needle into her hand, and the hand became much swollen. Dr. Hall Edwards took a photograph of the hand, and the needle was clearly seen. With the aid of the print, the foreign body having been localised, extraction was successfully carried out.

Vegetarians as Cancer Curers.

CANCER is a terrible malady, which has hitherto baffled the skill of the surgeon in its cure no less than of the pathologist as to its origin. Its treatment appears to exercise a perfect fascination upon a host of trespassers in fields medical. The vegetarians have now entered the happy hunting ground, and one of their leaders, Mr. A. F. Hills, has started a cottage hospital at Loughton, in Essex, for the reception of cancer patients for three, six, or twelve months, "according to the circumstances of the case." The main part of the programme is to be "a vegetable regimen, coupled with a plentiful use of distilled water." Our authority for this statement is the *Vegetarian*, which journal also states that this system was formerly carried out by the famous Mr. Abernethy, who gained some small success in suspending the progress of the malady. We cannot agree with the conclusion of the writer that if the progress of a disease be stayed for a time something has been done towards mastering that disease. It is often possible to check somewhat where one cannot altogether stop a runaway horse. For our own part, we believe that it would be just as feasible to arrest an avalanche with a row of market carts as to cure cancer with a diet of vegetables and distilled water. Few things are now impossible to the human intellect, and the bringing of this terrible malady, cancer, within the control of legitimate medical treatment will, in all probability, be a mere question of time.

The Scientific Treatment of Crime and Criminals.

DR. AUSTIN FLINT believes that the treatment of crime and criminals under the existing laws and their methods of execution is a serious failure, inasmuch as these are based upon the ancient idea of vengeance and retaliation in the form of punishment. He holds that the medical profession should at least endeavour to induce the judges, lawyers, and law-makers to study law in the light of modern scientific knowledge. As an abstract proposition, this is undoubtedly excellent, but experience has often shown that the legal mind is very difficult to influence in the direction indicated. Criminals may be divided into two classes—the curable and the incurable, and in the scientific study of crime the medical man has to do mainly with the occasional, the habitual, and the born criminal. Each obviously demands a different mode of treatment, if any satisfactory progress is to be made towards reformation. This matter is one which is well worthy of close attention, and might be made the subject of a useful and interesting inquiry by some competent prison medical officer.

Industries in Prisons.

THE decision to substitute productive for the present unproductive labour in prisons will generally meet with approval. The Prisons' Board will now provide work that will interest, and the knowledge of which will probably prove useful to prisoners on release; and a commencement of this new arrange-

ment has been made at Wormwood Scrubbs Prison. For male convicted prisoners, handmills for grinding wheat will supersede the crank machines; while washing and needlework for Government departments will replace, to a large extent, the oakum-picking by female prisoners. No doubt, in time, other methods of labour will be introduced which will be beneficial alike to the Government and the prisoners. Presumably, the treadmill is now doomed, and all such devices which did the prisoners no good, and were otherwise quite useless.

Leicester and its Refuse Removal.

THE "pail system" of closet clearance presents so many difficulties and drawbacks, that its speedy complete disappearance from all modern cities may be predicted with confidence. Leicester is well known for its peculiar views on many sanitary matters, but its citizens seem to have awakened, at any rate, to the advisability of adopting an improved method of sewage removal. The town authorities lately presented a petition to the Local Government Board for a provisional order which should empower a clean sweep of the present order of things. In consequence of this request, a special board of inquiry will shortly be sent to Leicester, when the whole circumstances of the case will be carefully investigated. One of the chief obstacles in effecting a reform of this kind is the cost that would be necessarily entailed. The Leicester Council has determined that in exceptionally bad cases, the cottage owner should be compelled to carry out the conversion at his own expense. In all other cases, however, they propose to defray the cost out of the public funds, and for that purpose to obtain the money by additional borrowing powers. As to this part of the project, no doubt, much may be said on both sides. Few persons would object to the relief of the small property owner by such a payment. On the other hand, however, many economists would at once condemn the proposal to make a huge addition to the value of the property of the wealthier owners. In other compulsory sanitary alterations, the fact that the house landlord has obtained a substantial addition to the value of his property is usually regarded as a sufficient counterpoise to the enforced drain on his pocket.

The Importation of Wines into America.

SOME remarkable figures with respect to the importation of champagne and other sparkling wines into the United States have been recorded. During the year 1875 the number of bottles of these wines amounted to 1,857,840; in 1885 the number increased to 2,608,152; and in 1895, just closed, 2,878,140. Enormous as these totals are, they are quite surpassed by the total for the year 1890, which was 4,753,836. Perhaps the latter year was one of great prosperity to American citizens, who very properly made the most of the time.

THE Duchess of York has appointed Sir John Williams, Bart., M.D., to be her Physician-Accoucheur; and the Duke of York has appointed Dr. Robert W. Burnet to be his Physician in Ordinary.

The Parasites of Malaria.

THE discussion on the parasites of malaria which took place at the last meeting of the Royal Medical and Chirurgical Society comes in curious juxtaposition with Dr. Lawrie's affirmation that Laveran's so-called plasmodium is a delusion and a snare. While this eminent observer declares his disbelief in the validity of Laveran's discovery, we over here are engaged in discussing whether particular parasites can be identified as the cause of particular varieties of malarial disease. Certainly the scepticism telegraphed from the far East found no echo among those who took part in this discussion, and until we are in possession of the data, on the strength of which Dr. Lawrie bases his repudiation of the association between the plasmodium and the genesis of malaria, we are entitled to continue to hold that the presence of this parasite is really the cause of the disease. It must be admitted that the parasites found in this association are numerous and present a picturesque variety in the matter of shape. It is, however, quite possible that many of the forms described and figured are really different stages in the evolution of the self-same parasite, but this is a conclusion which only long and painstaking observation can decide. An interesting collateral question was raised by Dr. Curnow, who challenged the conclusion arrived at by the authors of the paper, that malaria is not a water-borne disease. Their conclusion in this respect was based on researches carried out principally in a province in Spain, and it must strike everyone that in view of the extreme variety which obtains in the manifestations of diseases grouped as malarial, it must be unsafe to generalise on the strength of observations carried out in such a limited area. Certainly the instances alleged by Dr. Curnow of apparent infection through drinking contaminated water render it difficult to believe that malaria is never water-borne. In several recorded instances the disease attacked only those who partook of the contaminated water, the others escaping. Then, too, sailors are generally of opinion that they can trace the onset of the disease to their having made use of river water from malarial districts, and their opinion is supported by the fact that in many no other source of infection can be alleged. This is obviously a point of exceeding practical importance, and its significance is enhanced by the fact that sailors on vessels where condensed water is used suffer in vastly smaller proportion than their fellows on less-favoured ships.

Salvioni on Röntgen.

THE new rays of Professor Röntgen seem destined to have some day a wide field of application in many arts and sciences. In the meantime, one of the most extraordinary developments hitherto announced in connection with the new photography comes from Rome. According to the special correspondent of the *Daily Chronicle*, Professor Salvioni, of Perugia, has achieved no less a feat than the visual penetration of opaque bodies. The scientist mentioned has constructed an instrument called a cryptoscope, which, when fitted to the eye, enables the wearer, by means of the Röntgen rays, to see through opaque bodies. It

is added that the retina is impressed through the agency of the cryptoscope exactly in the same way as a photographic plate. If this news be true, it points to possibilities of an extraordinary nature. With such a marvellous extension of the human faculties as that foreshadowed by Salvioni, science may hope at an early date to acquire an enormous mass of hitherto unascertained physical phenomena. It seems not impossible that some of the more remarkable and important developments will profoundly affect the media of communication between the earth and the heavenly bodies.

Women as Prison Medical Officers.

THE question, as to whether or not a woman doctor is fitted to fill the post of Prison Medical Officer is now causing much diversity of opinion in the town of Cardiff. Many medical men, who do not disapprove of the admission of women to their profession, nevertheless, object strongly to this particular proposal. The chief argument advanced in favour of such an appointment is the familiar one that the female prisoners under certain circumstances would often prefer a female surgeon. With regard to this point it may be honestly doubted whether 999 out of every 1,000 of the women inmates would trouble their heads about the matter. Indeed, an air of unreality hangs about the whole affair, which has little immediate interest or value beyond the advancement of a principle. Under these circumstances we should advise the lady doctors to leave the prison appointments severely alone. Women are now admitted to the staffs of many medical charitable institutions, and have by strenuous perseverance opened up many fresh fields of medical enterprise. It would be a pity if by coveting too much they should run some risk of injuring their cause. There is no blinking the fact that their *clientèle* is for the most part drawn from the wealthier classes of the community, and that, so far, the poor do not flock to their ministrations in any ponderable numbers.

The Dublin Branch of the British Medical Association.

THE Annual Meeting of this Branch is announced as having been held a few days ago. As a medical organisation it does not seem to be an unequivocal success. It has existed for nineteen years and has had about a dozen honorary secretaries, and yet the outgoing president plaintively appealed to his audience to save the Branch from being shut up altogether for want of members and funds. The fact is that there is nothing for the Branch to do which is not much better done elsewhere, and it has, therefore, really no *raison d'être*.

THE Local Government Board have intimated to the Chelsea Board of Guardians that no objection would be taken to the appointment of a female practitioner as assistant medical officer for the Chelsea Infirmary, provided the Guardians were satisfied that suitable accommodation could be found for such an officer.

THE recent results of the Netley and London exa-

minations for the Indian Medical Service (eighteen surgeons) and Army Medical Staff (nine surgeons) show that Mr. Bukhla, who is a Hindoo, won four prizes. There was one failure in the Army Medical Service.

The New Electrophraphy ; Rontgen's Rays.

At the meeting of the Sheffield Medico-Chirurgical Society, held on Thursday last, Dr. Hicks, President of Firth College, very kindly gave the members a succinct *résumé* of all that was known as to the new process of electrographing, and placed before them very numerous examples, the result of his own experiments. For these experiments, he was very fortunate in securing a Crookes's tube, which appeared to be specially adapted for the work. It seems that all tubes are not alike, and that it is a matter of some difficulty to secure one that will answer the purpose properly, as the rays do not proceed from all parts of the tube alike. At Dr. Addison's suggestion, and in conjunction with him, Prof. Hicks made some beautiful electrographs of the hand, showing the bones and the bloodvessels injected with a preparation of lead, and also of the kidneys prepared in the same way. The result was in the highest degree interesting, as the circulation in both cases was beautifully illustrated, as far as the distribution of the vessels was concerned; nothing better could be desired. This appears to open out an important field for further results in the use of this wonderful discovery. Two electrographs were shown, in which the previously undiscoversible position of a needle in a foot, and in a hand, were at once demonstrated, and the foreign bodies easily removed. In one case, that of the foot, the needle was end up, and only showed as a small black spot.

DR. KNOWSLEY THORNTON will deliver the second Hunterian Society's lecture on Wednesday, February 26th, at 8.30 p.m., in the theatre of the London Institution, Finsbury Circus. The subject will be, "The Lines of Advance in Abdominal Surgery." Members of the profession are cordially invited.

THE latest returns of the Metropolitan Asylums Board show that scarlet fever is still prevalent in London. The total number of patients in the several fever hospitals of the Board suffering from this particular disease is now 3,020.

THE *Daily News* reports that Professor Virchow's assistant has succeeded in photographing a chloroformed frog with Röntgen rays in which the lungs of the frog in the act of breathing are distinctly seen.

THE Pharmaceutical Society have now turned their attention to Belfast, where they have prosecuted a firm of photographic dealers for selling bichloride of mercury.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

THE HONORARY DEGREE FARC.—Each year the Scottish Universities do themselves the honour of conferring honorary degrees on certain celebrated and, no doubt, deserving gentlemen. How far the Universities will go in this respect is only a matter of conjecture. If they only conferred these titles on well known and public men not much could be said against them, and the honour would be regarded as being of some value. We may divide the recipients of these empty titles into three categories:—First, those who have done something to deserve them, and whom it is an honour to the Universities to recognise in the only way open to them; secondly, those who have given large sums of money for the advancement of science, or to some infirmary, and who receive the honour as a *quid pro quo*; thirdly, and often the most numerous, local nobodies, especially if they happen to be personal friends of members of the *Senatus Academicus*. The *Senatus* of the University of St. Andrews has resolved to confer the honorary degree of LL.D. on Dr. George W. Balfour, of Edinburgh, already an LL.D. of the University of that city, and on Dr. Andrew Smart, also of Edinburgh, and one of the ordinary physicians of the Edinburgh Royal Infirmary, among others. To give Dr. Balfour a second degree of LL.D. seems to be a work of supererogation, but we suppose that it has been given on the principle of "scratch my back and I'll scratch yours," as Dr. Balfour is one of the University Court officials in favour of the enlargement of the medical school at St. Andrews. The other recipient of the degree is an amiable member of the medical profession who, we have no doubt, will be much surprised to find that he is a Doctor learned in the Law. We believe that at St. Andrew's each professor, it may be in rotation, has the right of proposing a name for an honorary degree. If this is so the degrees so obtained lose all their significance. It is a prostitution of what should be a jealously guarded right. The friendship of a professor and, it may be supposed, a little judicious adulation now and then, may, we presume, suffice to ensure a friend the coveted honour. Perhaps, in addition to the three classes of recipients enumerated above, a fourth might be added, namely, professors in other Scottish Universities, who appear to get the degree on the mutual admiration principle. A university which honours the officials of another probably expects a like honour in return in the persons of its own *Senatus*.

THE SCOTTISH UNIVERSITY M.D. UNDER THE NEW REGULATIONS.—There is some dubiety in University circles in Scotland how the clinical examination which is now necessary for the M.D. degree, in addition to the time-honoured thesis, is to be conducted. The prevalent feeling among the authorities seems to centre in a glorified M.B., C.M. clinical examination, in which the candidate for the higher degree should be asked to examine cases and report thereon, though he may be a physician of some standing, and to undergo an examination in the out-of-the-way branches of medical science, such as ophthalmology, laryngoscopy, and the like. If this be decided upon a great injustice will be done to the profession. For instance, a specialist for throat affections under the old regulations might send in a gold medal thesis on some branch of his speciality. If the suggested conditions are insisted on he may send in as good a thesis, but because he does not happen to know very much about medical electricity or the microscopic appearances of ringworm, he loses all chance of distinction and gains a mere pass. The plan that should be adopted in our opinion is as follows:—Each candidate, in addition to sending in his thesis, should be requested to send in the branch of medicine in which he would wish to be examined, that is if he has any preference, and is not an all-round Admirable Crichton. The University professors are supposed to know all branches of medical science, but might well be supported by expert assessors if necessary. Such a plan would be fair to all. Perhaps, however, the wish of the University professors to proceed with the new examination in the old way is due to a laudable wish not to expose their possible ignorance of special subjects, a supposed

ignorance which cannot be regarded as reprehensible when the rapid strides of modern medicine are considered.

THE TYPHOID OUTBREAK AT DUNBAR.—The history of this outbreak, as amended up to date, is a sad commentary on the achievements possible under the name of Local Government. East Lothian is the only county in Scotland, we believe, which chose the second alternative allowed in the Local Government Bill for the appointment of county medical officers. In the others, the medical officer of health is resident in the county, and is debarred from general practice. He is given a salary supposed to be sufficient for his wants. In East Lothian, a consulting medical officer was appointed, and subordinate medical men for the different districts. The consulting medical officer is a practitioner living in Edinburgh, who has not got a Public Health Degree, but who happens to be the surgeon to the local corps of Yeomanry. We have no wish to disparage this official's attainments, but such appointments are apt to render the working of the Local Government Bill nugatory. No one in the county seems quite to know who really is in authority, or who is responsible for reports and the ordering of inquiries. For instance, during the epidemic of typhoid fever at Dunbar, which we are glad to be able to report seems at last to be declining, the district committee of the county council did not meet for weeks after the commencement of the outbreak, and when they did meet, under the pressure of public opinion, they gave as a reason for their neglect, that they had delegated all powers to a public health sub-committee. This sub-committee met once, and in turn, delegated all powers to the district medical officer. In fact, the members of the sub-committee did not know whether they existed as an official body after the annual elections in December, and no meeting of the new council was held until January 21st. The position of affairs was rather involved. A serious outbreak of fever, a county council which did not meet, a sub-committee which did not know if they were defunct officially or not, a consulting medical officer of whom no mention is made in the reports on the subject, and a local medical officer in practice, on whom the brunt of the work and the odium attaching to it fell. It is to the credit of the last named that at length effective measures were taken to stamp out the fever. We will return to the subject next week.

TUBERCULOSIS: ITS CAUSE AND PREVENTION.—A memorial presented by the Medico-Chirurgical Society of Glasgow to the Health Committee of Glasgow Town Council "calling attention to the fact that tuberculosis is now fully recognised as an infectious disease, and asking them to take the matter into their serious consideration, with a view to protection of the community from infection," was remitted to Dr. Russell, Medical Officer of Health. Dr. Russell has just issued in pamphlet form an exhaustive report dealing with the whole subject, concluding with a number of practical suggestions. The report has been sent to all the medical men practising in Glasgow, and to all the public institutions. It is pointed out in the report that the local authority ought to resolve that, in the interest of public health, it is necessary that washing and disinfection should be carried out after every death from pulmonary consumption. Dr. Russell insists on the importance of taking immediate action in the direction of eliminating tuberculous cows from dairies, and for this purpose powers must be given to an expert veterinary surgeon.

THE PROPOSED MATERNITY HOSPITAL FOR DUNDEE.—After the grant of £5,000 by the Cobb Trustees there is every prospect of the proposed Maternity Hospital for Dundee soon becoming an accomplished fact. So far back as 1892 a scheme for the foundation of such an institution was partly sketched out by the Forfarshire Medical Association, and submitted to the Cobb Trustees, along with a request for substantial financial assistance. The suggestions of the Association consisted in substance of the erection of a hospital in a central part of the city, with accommodation for twenty beds, arranged in two series, to be used alternately on hygienic grounds, and each series to consist of two wards of four beds each, an isolation ward, and another ward. The cost of erecting and finishing such a building was estimated at about £5,000, and the annual expenditure about £800. In order not to depend for the income altogether on public subscriptions, it was intended that at the outset there should be an endowment, from which about half of the annual expenditure could be

obtained. It was considered that before anything could be done it would be necessary to have at least £10,000 in hand. This scheme is still being prosecuted by the Medical Association, and, besides the £5,000 given by the Cobb Trustees, donations of £1,000 and £500 have also been promised. There has not yet been time to take any definite steps for securing a building, but large houses in different parts of the city have been spoken about. It is expected, however, that next week a forward step will be taken in the matter.

As in many other parts of the country, the unseasonable warmth of the past month has had a remarkable effect on the death-rate in Edinburgh. Notwithstanding the old adage about a green yule, it is many years since the mean temperature has been so high, and the mortality so low, in January. The mean temperature for the month was 2.6° over the average, the death-rate 14.75 per 1,000, or 6.77 per 1,000 below the average for the last five years.

EXAMINATION PAPERS FOR THE DIPLOMA IN PUBLIC HEALTH AT THE UNIVERSITIES OF OXFORD, CAMBRIDGE, DURHAM, (a) AND VICTORIA. AND THE CONJOIN BOARD OF ENGLAND.

(Continued from page 124.)

OXFORD, NOVEMBER 27TH, 1895.—PART II.

10 a.m. No. III.—*Preventive Medicine.*

1. How may the nature of the soil on which a dwelling-house is constructed produce conditions injurious to health? Discuss the relative advantages and disadvantages of gravel and clay soils.
2. What are the practical difficulties usually met with in the case of the "Common Lodging Houses" and "Tenement Houses" of the poor quarters of large towns in maintaining the water-carriage system of excrement removal in a wholesome condition? Describe the kind of water-closet which is in your opinion best suited to the circumstances. Illustrate your description by diagrams.
3. State what you know about the occasional unwholesomeness of the following kinds of preserved food; how this occasional unwholesomeness is manifested; and to what you believe it is due: viz., ham or bacon, tinned lobster, and tinned fruits.
4. Describe the leading characters of Rickets. To what extent do you consider it is influenced by insanitary conditions?
5. Enumerate and describe the rashes that may resemble the eruption of Scarlatina, giving the differential diagnosis in each case.
6. What is the essential difference between an antiseptic and a disinfectant? Give examples of each, and state shortly in what circumstances they, severally, are useful.

2 p.m. PART II.—No. IV.—*Preventive Medicine.*

1. You are consulted as to the hygienic regulation and management of an Industrial School. What diseases would you expect to occur in such an institution, and what measures would you advise for preventing their occurrence and spread?
2. A village consisting of one hundred and fifty houses, chiefly labourers' cottages, is situate on the banks of a rapid stream flowing to a river from which a large town takes its water-supply at a point twelve miles below the village. The "dry-earth" system has been adopted in the village, and it is contended that its drainage cannot therefore seriously pollute the stream. What are your views on this question?
3. Enumerate the provisions of the Public Health Act, 1875, against the spread of infection from infected persons and things.
4. In what respects and to what extent may the general death-rate of an "Unhealthy Area" be influenced by causes independent of sanitary administration or local sanitary conditions.
5. Enumerate, in the order of their importance, the matters in which sanitary authorities have power to make bye-laws for the safeguarding of the Public Health.
6. The District Council of a well-to-do suburban district,

(a) Examination for the Degree of Bachelor in Hygiene, and for the Diploma in Public Health (D.P.H.) Durham.

with a population of about twelve thousand, is about to reorganise its staff for sanitary purposes. The question arises whether it is desirable for the offices of Building Surveyor and Inspector of Nuisances to be held by the same person. Give your own views on this subject.

CAMBRIDGE, THURSDAY, OCTOBER 3RD, 1895.—PART II., PAPER I.

1. What advice would you give by way of securing such care and control of milch-cows as would tend to prevent the spread of bovine tuberculosis on a dairy farm? Differentiate between such recommendations as can be enforced by any local authority and those which must be left to the discretion of the dairy farmer. Explain your grounds for each recommendation.

2. The council of an urban district of 20,000 inhabitants have requested from you, as their Medical Officer of Health, a report on the subject of the provision by them of a hospital for the isolation of small-pox, together with an explanation of the grounds on which each point you refer to is based, especially in regard to the position and construction of such hospital. Write out such a report.

3. It is sought to provide a wholesome water-supply for a village which has at present no available water except from ponds and ditches, and which lies on a deep layer of subsoil clay. Explain the various ways in which such a supply may, under differing local circumstances, be procurable.

4. Give an account of the history of small-pox in this country during the last fifty years. Specify the various legislative and other administrative measures which have been taken during that period to control this disease. Explain, as regards each such measure, how far it has succeeded or failed.

5. Explain the law as to Nuisances under the Public Health Act, 1875. Give an account of the several steps to be taken by the local sanitary authority and their various officers to secure the abatement of an ordinary nuisance and of one that is likely to recur.

FRIDAY, OCTOBER 4TH, 1895.—PART II., PAPER II.

1. To what extent does local injury from previous disease affect the susceptibility of the body to microbic diseases? Illustrate your remarks by reference to facts relating to the prevalence of such diseases.

2. Give the relative rates of mortality at the different ten-year age periods, from fifteen years and upwards, from the following classes of disease; cancer, phthisis, diseases of the nervous system, of the circulatory system, of the respiratory system (not phthisis), and of the digestive system. State the influence to which each such incidence of disease is probably due.

3. Give some account of researches upon the prevalence of disease in "back-to-back" houses, and draw out plans for their conversion into more healthy habitations.

4. Describe any efficient measures for the disinfection of houses, clothing, &c., after the occurrence in them of infectious diseases. Give your reasons for employing the means of disinfection that you select.

5. Draw out a list of the diseases that may arise from drinking impure water, and, with reference to cholera and enteric fever, describe the conditions under which infection from this source is likely to occur.

6. Describe in detail the measures necessary for the prevention of diphtheria.

(To be continued.)

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

THE EDINBURGH M.D.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your Journal of January 29th ulto., states that "under the new regulations, the candidate for the M.D. may pass a further examination in Clinical Medicine, and thus escape the ordeal of furbishing up Greek or Moral Philosophy." You remark, on this,—“The University of Edinburgh appears to be acting wisely in making the path

of its alumni as smooth as may be from starting point to goal.”

I am aware that the "further examination in Clinical Medicine," for the final M.D., may be made a very wide and searching test; indeed, such a kind and degree of clinical test, should be, of necessity, a strict part of the M.D. examination, but I venture to differ from you, if you think that any feebly severe or strict test in clinical medicine can justify the omission of logic or psychology or philosophy. It is precisely in that kind of culture which the study of these subjects gives, which is so lamentably absent from the medical mind. It is not that the study of logic or psychology gives any new facts of "practical medicine" to the student, but it opens his eyes to the method and relativity of all knowledge and of all facts. The mind which has studied logic or the history of the growth and evolution of human knowledge, or the great principles which lie at the root of what philosophers call "education," will be, throughout the life of the individual, vastly aided in correct generalisation in his profession and practice; he will be able to form juster conceptions of new theories and new methods of practice; he will be, in the best sense of the word, a far more "educated" man than if his culture be confined to the technicalities of his profession.

Unless this basis of philosophic method and culture come to the medical man early it will very rarely, if at all, be attained afterwards. Such culture lays the foundation for a just modesty of mind; it shows the young man in how great a world his field of work lies; he is enabled to see, in his own work and studies, that the higher method of all philosophy exists. The young man will often, by a study of logic and philosophy, be saved from the narrow arrogance, which the knowledge and practice of technical professional work only, is apt to induce. This higher kind of culture, this breadth of view, this conception of the relativity of all knowledge, of the unity of method of all knowledge, this culture for the sake of "sweetness and light," this method for the fuller use and understanding of bare facts, is all the more important now for the higher degrees in medicine, seeing that the varied licensing bodies are pouring forth such a vast number of "qualified" "physicians and surgeons" (M.R.C.S., L.R.C.P., &c.), men who, in the main, have little preliminary education, and who have no time, in their five years' curriculum, to look at anything but the bare facts needed for their searching examinations. These men are usually at once absorbed into the "business" of practice, and culture never or rarely comes to them afterwards.

Uniformity of curriculum in medical education would be a great calamity; nor less a calamity would be the "one-portal" system, or the domination of any great society having very much the spirit of a "trades-union." Medicine is not a mere technical art, but it is part, and a very great part, of all science and all philosophy. It is, therefore, reasonable and right, that those who aspire to the higher—or what should be the higher—degree of M.D. should give proof that they have seen into the Method of the human mind in knowledge; should give proof that they can arrange their ideas in an orderly fashion, and can draw inferences with a logical severity of truth.

Holding these views, I cannot but feel that the University of Edinburgh has made a very retrograde movement. Just when the philosophies of Hume, Kant, &c., are beginning to be understood in England, and at a time when men's minds need steadying under the great waves of progress which have followed Darwin, F. Schlegel, &c., the University of Edinburgh has deprived its alumni of a very ancient light of true method.

I am, Sir, yours, &c.,
SALISBURY CRAIGS.

Edinburgh, February 12th, 1896.

Medical News and Pass Lists.

National Hospital for Consumption, Ventnor.

THE Report of the 27th year of the operations of this well-known hospital for chest diseases, adopted at the annual meeting of governors held on Thursday last, shows that the work has gone forward steadily and satisfactorily

The Board of Management have accommodation for 134 patients, in ten blocks of houses situated in the Undercliff, Isle of Wight, each patient being provided with a separate bedroom facing south and overlooking the sea; and while every bed continues to be occupied, there are a large number of cases for which there is at present no accommodation. The total receipts in 1895 amounted to £15,133 (including legacies £4,623), and the expenditure to £11,160. The number of patients treated was 778, some of whom were resident as long as 30 weeks, though the average stay was nine weeks; 34 died, and 509 were improved in health by treatment. As the annual subscriptions are only £2,361, an effort will be made this year to obtain the necessary funds for maintenance by a festival dinner in London on April 29th, at which the Attorney-General (Sir Richard E. Webster, G.C.M.G., Q.C., M.P.) will preside. Mr. George J. Drummond was unanimously elected treasurer of the hospital. The re-election of the retiring members of the board and auditors, and a vote of thanks to the chairman, brought the proceedings to a close.

Hospital Finance.

A CRISIS has developed in the affairs of the North-West London Hospital, in the Kentish Town Road, N.W. Lord Rathmore, the Chairman of its Committee of Management, reports that the Treasurer, (Mr. George Herring) says that, in his opinion, the hospital must be closed at once, unless it can attract more support. He has in hand £300, whereas the institution owes a debt of £2,000, and entails an expenditure of £80 a week against an income of only £16 per week from annual subscriptions. Mr. Herring offers to subscribe a sum equal to one-third of the result of a special appeal.

The Hunterian Society.

THE annual General Meeting was held on Wednesday, Feb. 12, in the London Institution, Mr. C. J. Symonds, President, in the chair. A cordial vote of thanks to the retiring President was passed by acclamation, and after the usual compliments to the officers of the past year, the following list was unanimously elected for the coming year:—President: Dr. G. E. Herman. Vice-Presidents: Drs. R. H. Fox and A. T. Davies, Messrs. T. Mark Trevell and T. H. Openshaw. Treasurer: Dr. F. C. Turner. Trustees: Dr. H. P. Fotherby and Mr. F. M. Corner. Librarian: Dr. A. T. Davies. Orator, 1897: Dr. Hingston Fox. Secretaries: Dr. Fred J. Smith and Mr. A. F. Tubby. Council: Drs. T. H. A. Chaplin, J. M. Etkles, B. Dawson, T. G. Lyon, J. W. Oliver, W. Rawes, Henry J. Sequeira, St. Clair, B. Shadwell, J. T. Woods, Messrs. Hope Grant, C. J. Symonds, J. H. Targett. Auditors: Dr. T. G. Lyon, and Messrs. F. G. Brown, Hope Grant, T. R. Humphreys. The Fellows then adjourned to the Theatre of the London Institution to listen to the Annual Oration, delivered by Dr. G. Newton-Pitt, on "Hunter and His Contemporaries, with Special Reference to Hunter as a Clinician, and his Influence on the Medical Societies of his Time," a full report of which will appear in the Transactions, and a large portion, we hope, in the journals, as of much wider interest. After a warm vote of thanks to the orator, proposed by Dr. Davies, and seconded by Dr. James H. Sequeira, the meeting dissolved. The Annual Dinner was held at the First Avenue Hotel, on Friday, Feb. 14th. Sir Joseph Lister honoured the Society as a guest at this function.

Vital Statistics.

THE deaths registered last week in thirty-three great towns of England and Wales corresponded to an annual rate of 20.5 per 1,000 of their aggregate population, which is estimated at 10,860,971 persons in the middle of this year. The deaths registered in each of the last four weeks in the several towns, alphabetically arranged, corresponded to the following annual rates per 1,000:—

Birkenhead 16, Birmingham 20, Blackburn 15, Bolton 26, Bradford 17, Brighton 20, Bristol 18, Burnley 18, Cardiff 17, Croydon 15, Derby 17, Dublin 24, Edinburgh 17, Glasgow 19, Gateshead 21, Halifax 24, Huddersfield 15, Hull 18, Leeds 20, Leicester 22, Liverpool 25, London 20, Manchester 21, Newcastle-on-Tyne 16, Norwich 25, Nottingham 16, Oldham 21, Plymouth 19, Portsmouth 19, Preston 22, Salford 22, Sheffield 20, Sunderland 24, Swansea 15, West Ham 16, Wolverhampton 24. The highest annual death-rates per 1,000 living, as measured

by last week's mortality were:—From measles, 1.6 in Leicester, and 4.8 in Norwich; from whooping-cough, 1.7 in Salford, and 3.9 in Bolton; from fever, 1.3 in Bolton; and from diarrhoea, 1.0 in Burnley. The death-rate from scarlet fever did not reach 1.0 per 1,000 in any of the large towns. The 102 deaths from diphtheria included 63 in London, 5 in West Ham, 5 in Birmingham, and 3 in Edinburgh. One death from small-pox was registered in Swansea but not one in any other town.

The Mortality of Foreign Cities.

THE annual death-rate per 1,000 in the principal foreign cities according to the weekly returns communicated to the Registrar-General, is as follows:—Calcutta 39, Bombay 31, Paris 22, Brussels 17, Amsterdam 17, Rotterdam 17, The Hague 13, Copenhagen 15, Stockholm 16, Christiania 18, St. Petersburg 34, Moscow 36, Berlin 17, Hamburg 16, Dresden 18, Breslau 19, Munich 21, Vienna 23, Prague 23, Buda-Pesth 21, Trieste 23, Rome 23, Turin 20, Venice 38, Cairo 51, Alexandria 34, New York 23, Brooklyn 21, Philadelphia 23, New Orleans 30.

Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and Faculty of Physicians and Surgeons of Glasgow.

At the quarterly Examinations for the Triple Qualification held in Edinburgh during January the following were the results:—

First Examination, Four Years' Course.

Of 24 candidates, 11 passed, viz.:

Alfred John William Noble, William O'Sullivan, Joseph Horgan, Francis Carter, Alfred Sigismund Powell, Eldred Ladyman, William MacKirdy, Edward Bennett, James MacRae, George Robert Harland, and Timothy Murphy.

And three passed in one division of the Examination.

First Examination, Five Years' Course.

Of 28 candidates, 11 passed, viz.:

Edith Neld, Robert Jackson Mackay, Charles Richardson White, George Henry Fullarton Graves, Edward Parker Haythornthwaite, David Coffey, John Blunt Swinden, William Arthur Dawson, Agnes McLean Black, James Patrick Lavery, and Lizzie Beatty.

And 6 passed in one or two divisions of the examinations.

Second Examination, Two Years' Course.

Of 52 candidates, 21 passed, viz.:

Maurice McSherry, Thomas Killips Greenfield, George Crofts Beamish, Robert Hamilton Fleming, Robert Phillip Graham, Berlyvine Goldsmith Roscoe, John Robert Askew, Eldred Ladyman, John Kirkpatrick, Anthony Joseph Renouette, Samuel David Clements, Denis Nyhan, Edward Eumbant Kellett, John Henry O'Sullivan, Thomas Harold Waddington, John Titus Newton, Charles Herbert Thackrah, Robert Stenhouse Williams, James Charles Bouchier-Hayes, Percy Ashworth Wedgwood, and Clayton Simpson.

And 13 passed in one or two divisions of the examination.

Second Examination, Five Years' Course.

Of 12 candidates the following 8 passed:—

Abraham Johannes Benjamin Albertyn, John Tobin (with distinction), Henry Fowler, Thomas Neville, James Ross, Charles John Grig, Vaughan Bateson, and James Sharp Hamilton.

Third Examination—Five Years' Course.

Of 8 candidates, 7 passed, viz.:

James Murray, John St. John Murphy, Albert Fletcher Jones, George Herbert Arthur Taylor, Joseph Martin Donovan, Richard Francis Flood, and Georgina Collier.

Final Examination.

Of 137 candidates the following 65 passed, and were admitted L.R.C.P.E., L.R.C.S.E., and L.F.P. & S.G.:—

Elizabeth Henderson, William Henry Rowthorn, Arthur James Troughton, Charles Graves, Arthur Bishop Carey Ormrod, Emilia Margaret Guthrie, Richard Wolfendale, Bryce Johnstone Macaulay, Walter Pearson, Martha Florence Armitage, Selim Hishmeh, David Alexander, Charlotte Susannah Vines, Samuel Robb, Elizabeth Mary Cooper, James Blewitt, Henry Greaves, Percy Sandiland Vesteven, Robert Willbond, Walter Scharengrüvel, Percy Ridley Gange, Herbert Arthur Lake Banham, Edward Buller Hicks, Joseph William Furey, Daniel Urban Hanley, Denis Hennessy, John Collingwood Thompson, Arthur Wellesley Ball, Annie Gillespie, Solomon Harold Richards, Joseph O'Meara, Walter Squibbs, John Ewart Martin, Thomas Aspinall, Andrew Morris Stewart, Eric Norham, John Edmund O'Ryan, Thomas Canning Hunter, Patrick Bernard Molony, James Munce, Alexander Jason Hassard, Richard Lester Park, William Barclay Thomas, James McAllister Ramsay, Timothy O'Callaghan, Hendrik Jan Van Brock, Douglas Albert Robinson, Thomas Francis Elmes, Henry Edward Birmingham, Thomas William Herbert Young, Thomas Matthew Donovan, Thomas McKinlay, Martin Cleary, George Gillon Irving, William Hugh Jones, Thomas Bannerman, George Henry Field, Maurice Hickey Knight, Thomas Graeme Dickson, Hugh Sommerville Doble, Ernest Brice, Alexander McLellan Wilson, Benjamin Hilton Leigh, William John Nixon Davies, Charles Herbert Harris, and thirteen candidates passed in one or more divisions.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

REPRINTS.—Authors of papers requiring reprints in pamphlet form after they have appeared in these columns can have them at half the usual cost, on application to the printers before type is broken up.

M.R.C.S. (Manchester).—The matter is unfortunately of every day occurrence, and is apparently on the increase. Although regrettable, it is hardly one to bring before his College, it is more a question of etiquette and gentlemanly feeling, of which your neighbour evidently possesses a very small modicum.

THE KISBY FUND.

To the Editor of THE MEDICAL PRESS and CIRCULAR.

SIR,—I shall be glad if you will allow me to acknowledge the receipt of the following subscriptions to this Fund, in addition to the list published in your issue for January 29th.

I am, Sir, yours, &c.,

Carrickmacross.	P. MCKENNA, M.B., Hon. Sec.		
Dr. H. Stear, (Saffron Walden)	£1	1 0
Dr. Jas. G. Cahill (Ballinacary)	1	0 0
Dr. W. G. Dunwoody (Monaghan)	0	10 6
Dr. McQuaid (Coothill)	1	0 0
Dr. R. M. Target	1	0 0

DR. J. B. T. (Preston).—We shall be glad to receive the MS., and, if possible, insert the paper in an early number.

GUY'S TONIC COMPANY.—We received a long communication from the Manager of this Company as we were at press, animadverting on some remarks made by us on "quack medicines." We hope to deal with this in our next.

DR. F. T. S.—We have forwarded your letter to the address of the gentleman concerned, who is, we understand, abroad at present.

MR. MOADAM BOOLE'S Lecture on "Hernia" is marked for early insertion.

THE TRIALS OF THE PROFESSION.

DOCTOR (to husband of patient): Your wife is in a critical state, I should advise you to call in a specialist to consult on the case.

HUSBAND: Yes, I told my wife long ago that she ought to get proper medical advice, but she thought you would be offended.

Meetings of the Societies.

WEDNESDAY, FEB. 19TH.

NORTH-WEST LONDON CLINICAL SOCIETY.—8 p.m. General Meeting.—8.30 p.m. Clinical Meeting.

ROYAL MICROSCOPICAL SOCIETY, (20 Hanover Square, W.)—8 p.m. Mr. F. R. Dixon Nuttall: On the Male of *Stephanoceros Eichhornii*.—Messrs. W. and G. S. West: New Freshwater Alga.

THURSDAY, FEB. 20TH.

HARVEIAN SOCIETY (Stafford Rooms, Titchborne Street, W.)—Dr. J. E. Squire: Some Clinical Aspects of Pneumonia.

SOCIETY OF ANESTHETISTS, (20 Hanover Square, W.)—8.30 p.m. Dr. Prince Stallard (Manchester): Pental, Its Administration in 150 Cases.

ROYAL INSTITUTION.—8 p.m. Prof. H. Marshall Ward: On Some Aspects of Modern Botany.

FRIDAY, FEB. 21ST.

ROYAL INSTITUTION.—9 p.m. Mr. E. Frankland: The Past, Present, and Future Water Supply of London.

Vacancies.

Birmingham Provident Dispensary (Sands Cox Trust—Hockley Branch).—Medical Officer. Minimum salary £250, with residence and gas. Full particulars of the Secretary, A. Derrington, 20 Weston Road, Handsworth, Birmingham.

Buckinghamshire General Infirmary, Aylesbury.—Resident Surgeon and Apothecary, unmarried. Salary £80 for the first year, with an advance of £10 per annum until it amounts to £100, with board, lodging, &c. Original testimonials to Mr. George Fell, Solicitor, Aylesbury before February 24th.

Cumberland Infirmary, Carlisle.—An Assistant House Surgeon. Salary £40 per annum, with board, lodging, and washing. Applications to the Secretary before Feb. 25th.

East Suffolk and Ipswich Hospital.—Second House Surgeon. Salary £70 per annum, with board, lodging, &c. Applications, with testimonials, to the Secretary on or before Feb. 25th.

Great Northern Central Hospital.—House Physician. Salary £60 per annum, with board, lodging, &c. Applications, with testimonials, to the Secretary on or before Feb. 25th.

Lincolnshire County Hospital.—Assistant House Surgeon. An honorarium of £10 for each period of six months, with board and residence. Applications, with testimonials, to the Secretary on or before Feb. 22nd.

Salford Royal Hospital.—House Surgeon. Salary £100 per annum, with board and residence. Applications to the Secretary by Feb. 22nd.

Sheffield General Infirmary.—Junior Assistant House Surgeon. Salary £50 per annum, with board, lodging, &c. Applications, with testimonials, to the Medical Staff of the Sheffield General Infirmary, to the care of the Secretary, on or before Feb. 29th.

Sheffield Royal Hospital.—House Surgeon. Salary 170 guineas per annum, with board and lodging. Applications, with testimonials, to Dr. Sinclair White, Secretary to the Hon. Medical Staff, on or before Feb. 26th.

Sheffield Union.—Resident Assistant Medical Officer. Salary £100 per annum, with apartments, rations, and the other usual allowances. Applications, with testimonials, to Joseph Spencer, Clerk to the Guardians, on or before Feb. 26th.

Victoria Hospital, Folkestone.—House Surgeon. Salary £80, rising £10 annually, with board, residence, and washing. Applications, with testimonials, to the Secretary by March 20th.

Appointments.

COLMAN, W. S., M.D. Lond., M.B.C.P., Assistant Physician to the National Hospital for the Paralyzed and Epileptic, Bloomsbury.

EDMOND, G. M., M.D., C.M. Aberd., Second Assistant Physician to the Royal Infirmary, Aberdeen.

ELSWORTH, R. C., M.B., C.M. Edin., M.E.C.S., Visiting Surgeon to the Swansea Hospital.

GARSTANG, F. W., M.R.C.S., Medical Officer of Health to the Northwich Urban District Council.

HAINES, EDWARD, L.M.C.P. Lond., M.R.C.S., Junior Medical Officer for the Infirmary of the Wandsworth and Clapham Union.

JONES, RICHARD, M.D., C.M. Edin., D.P.H. Camb., Medical Officer of Health for the Urban District of Festinog.

KENDALL, HERBERT W., M.R.C.S., L.R.C.P. Lond., Assistant Surgeon to the Bristol Hospital for Sick Children and Women.

MORRIS, C. D., L.R.C.P. Lond., M.R.C.S., Medical Officer of Health by the Sunbury District Council.

NITCH-SMITH, REGINALD, L.R.C.P. Lond., M.R.C.S., House Physician to Westminster Hospital, S.W.

ODELL, R., L.R.C.P. Lond., M.R.C.S., Assistant Honorary Medical Officer to the Hertford General Infirmary.

PROK, E. G., L.R.C.P. Edin., M.R.C.S., Medical Officer for the Queensbury Sanitary District of the Halifax Union.

WARD, FRANCIS, M.B., C.M. Edin., Senior House Surgeon to the East Suffolk and Ipswich Hospital.

WILSON, S., L.R.C.P., L.M. Edin., Medical Officer for the Enniskillen Workhouse Infirmary.

Births.

CHAPMAN.—Feb. 12th, at 1 St. John's Street, Hereford, the wife of Paul M. Chapman, M.D. Lond., F.R.C.P., of a son.

DRACON.—Feb. 11th, at Warrington House, West Crofton, the wife of J. G. Deacon, M.D. Irel., of a daughter.

WILLIAMS.—Feb. 8th, at Fairfield, Pontypridd, Glam., the wife of T. R. Hamlen Williams, M.R.C.S., L.R.C.P., of a daughter.

Marriages.

CURRIE—GUBBINS.—Feb. 8th, at Harrismith, Orange Free State, Oswald James Currie, M.B. Lond., M.R.C.S.E., of Marlburg. Natal, eldest son of Alexander Currie, of Blackheath, Kent, to Sara, second daughter of the late George Gough Gubbins, of Summerville, Co. Limerick.

HOSKINS—PASCHAL.—Feb. 12th, at St. Nicholas Parish Church, Chiswick, William Hoskins, M.B. Aberd., of Lansdowne House, Brookbourne, to Georgina Augusta, only daughter of the late Col. Paschal, 70th Regt., of Morton House, Chiswick.

HOWARD—CUNNINGHAM.—Feb. 8th, at St. Saviour's, Aberdeen Park, John Alexander Howard, M.D. Lond., only son of John Howard, of Ashby Road, Canonbury, to Emily Gertrude eldest daughter of the late Chas. Cunningham, of Balfour Road, Highbury New Park.

PATON—PERSHORE.—Feb. 12th, at St. Mary Magdalene, Up-on-Torquay, Henry H. L. Patch, M.R.C.S., L.R.C.P. Lond., of Chudleigh, to Elizabeth, eldest daughter of Francis Pershore, of Chelston Towers, Torquay.

Deaths.

COLLUM.—Feb. 12th, Archie Tillyer Collum, M.B., F.R.C.S., of 7 Grosvenor Street, London, W., aged 28, fifth son of Surgeon-Major Robert Collum, M.D., M.R.C.P., of Enniskillen, Co. Fermanagh.

EDIS.—Feb. 8th, at Barton Street, Gloucester, Thos. Edis, M.R.C.S., L.S.A.

EKIN.—Feb. 14th, at his residence in London, Surgeon-General Jas. Ekin, C.B., M.B. Lond., aged 67.

HARDCASTLE.—Feb. 11th, at 18 Chester Crescent, London, late of Newcastle-upon-Tyne, Hugo Macaulay Hardcastle, M.D., aged 36.

HOOPER.—Feb. 14th, at Allandale, Southampton, Chas. Hooper, M.R.C.S., aged 75.

SAUNDERS.—Feb. 16th, at Hartham Road, Camden Town, Thos. J. Saunders, M.R.C.S., L.R.C.P., aged 32.

SWIFT.—Feb. 6th, at 14 Leyburn Terrace, Dover, Benjamin Pratt Swift, M.D., Deputy-Inspector-General of Hospitals, late 14th and 96th Regiments, aged 79.

TUXFORD.—Feb. 15th, at his residence, The Square, Boston, Lincolnshire, James Ed. Tuxford, M.R.C.S., J.P., aged 92.

WALKER.—Feb. 9th, at 54 Fulham Park Gardens, S.W., the Rev. Hyde Edwards Walker, M.A. Oxon., L.R.C.P. Lond.

NOTES ON A CASE OF SUPRA-VAGINAL HYSTERECTOMY. PERFORMED DURING PREGNANCY

FOR
THREATENED INTESTINAL OBSTRUCTION. (a)

By G. ELDER, M.D.,

Surgeon to the Samaritan Hospital for Women, Nottingham.

THE patient from whom the specimen was taken which I exhibit this evening, is 37 years of age, and was married three years ago. She comes of a very hardy stock and had herself always had exceedingly good health prior to marriage and since, excepting increasing difficulty in having her bowels relieved, until a few weeks before consulting me. Although menstruation had always been very free, it was regular and remained so until three or four months before her illness, when it ceased. Marriage had not affected the amount or the regularity of the flow, and up to her illness she had not the faintest suspicion of being afflicted with pelvic mischief. As above mentioned, constipation had been suffered from for a long time past, but this had become very much worse during the past five or six months, and during the latter five or six weeks of this period, relief could only be had by the use of increasingly large doses of aperients. In addition to this symptom there had troubled the patient only since her marriage frequently recurring attacks of sickness. The cessation of the menses for four months coupled with enlargement of the breasts, made the patient suspect herself pregnant. The illness which culminated in the operation shortly to be described, began suddenly on the 12th of last December with violent sickness which continued almost continuously day and night for three days; and for four days thereafter, it was excited by any attempt to take food. The vomit was bilious in character, and although towards the latter part, it is described by the patient as being "thick, dirty-looking stuff," it does not seem to have been feculent. Repeated enemata failed to relieve the bowels until the seventh day, when a small motion was passed, and from this time onwards, until January 1st, when she saw me, despite the use of the same means, assisted by aperients, there had only been two good stools, these being on December 31st and the morning of January 1st respectively. During her illness, she had become very sallow, and lost considerably in flesh, and it was felt by her medical attendant, Dr. Rafferty, of Waltham, who, throughout had recognised the gravity of her condition, that an operation offered the patient the best chance of recovery. On examining her abdomen, there could be seen and felt a somewhat prominent tumour, rising up from the pelvis to within an inch of the umbilicus, consisting of a major central portion, of which the upper part felt like the pregnant uterus. Two offshoots could very distinctly be felt running up from the uterine mass, the left and larger was very irregular in shape, whilst that on the right seemed to have a closer connection with the parent

tumour and consisted of two or three somewhat large nodules.

Per vaginam the os could be felt with difficulty, as it was pressed to the left by a large solid, evidently fibroid, growth, which completely blocked up the pelvic outlet.

On January 4th supra-vaginal hysterectomy was performed in the following manner:—First of all, both broad ligaments were tied off, so as to minimise the risk of tension, then the uterine appendages were removed, and, now, on lifting up the growth preparatory to its removal, a coil of small bowel, from three to four inches long, was found firmly attached to its upper surface. Fortunately, without interfering with the integrity of the bowel, the adhesions were freed and ligatured. A provisional elastic ligature being passed round the uterine neck, a circular incision through the peritoneal investment was made a few inches above, and the whole mass shelled out. Nothing now was left but part of the cervix, and when the uterine arteries were ligatured, the elastic ligature was removed, and bleeding points controlled by ligature or pressure from the several layers of sutures which were put in to bring together the raw edges of the stump. This having been fixed at the lowest angle of the wound, the abdominal parietes were brought together in the usual manner, provision being made for drainage by a glass tube passed down to Douglas's pouch. The patient bore the operation well, but some eight hours afterwards, probably as the result of sickness, the surface of the stump bled freely, to check which it had to be somewhat opened up and its surface desiccated by the solid perchloride of iron and pressure applied. Although this incident has somewhat prolonged the convalescence of the patient, in other respects recovery has been uneventful, and she is returning home this week with her wound perfectly healed.

The patient had the first week considerably more pain than is usually found accompanying this treatment of the stump, and it was not until the fifth day that the fluid drained off became clear and allowed of the removal of the glass tubes. As will be seen from the charts which I hand round, the temperature only once ran above 100°, viz., on the evening of the 8th day, and the pulse, except on the 1st, 2nd, 3rd, 4th, 5th, 6th, and 7th days, never went above 100.

Description of the Tumour.—The specimen, as will be seen, consists of the uterus cut through the cervix, and containing a foetus eight inches in length together with the amniotic fluid. In the region of the left broad ligament there is a series of pediculated myomatous nodules of irregular shape, in all about the size of a foetal head at term. Anterior and posterior to this there are two separate nodules of the size of a guinea fowl's and hen's egg respectively. Occupying the uterine wall on the right side there is a more flattened myomatous mass, and at the fundus and behind the cervix there are also other nodules. (The whole tumour has shrunk very much since its removal six weeks ago, more especially the uterine cavity, although the foetus was not removed until after the finish of the operation.)

Comments.—Although there are many points of interest in this case the one to which I wish to specially

(a) Read before the British Gynaecological Society, Feb. 13th, 1896.

invite your attention is the evident connection which marriage bore to the perilous illness of the patient. Some eighteen years of menstrual life had been passed without the patient ever suspecting herself to be suffering from any uterine trouble. Almost a parallel condition of matters was experienced in the case of the Porro operation which I described at this Society last November, where the woman up till the moment of labour believed herself to be absolutely healthy.

Lectures

ON

THE DIAGNOSIS OF INSANITY.

By THEO. B. HYSLOP, M.D.,

Lecturer on Mental Diseases to St. Mary's Hospital Medical School,
Assistant Physician to Bethlem Royal Hospital.

LECTURE IX.—(Conclusion.)

THE possession of an unstable nervous system is attended with a peculiar liability to easily succumb to the effects of heat. This is seen in a marked degree in the Mongolian and Kalmuc type of idiocy. Their circulation is usually feeble. They advance in summer and undergo retrogression in winter. They undergo, in fact, a species of hibernation. Not only are they prone to chilblains and froetbites, but they are little tolerant of excessive heat and proximity to a fire, which to many would be only agreeable, would to patients of this class be attended by a serious blistering of the legs even when protected by stockings or other articles of clothing. (a) I have seen several cases of syncopal attacks, and one of an asphyxial character occurring in imbeciles after exposure for a few hours to a hot sun, and their exceeding proneness to be affected in this manner by heat renders it necessary to exercise care during the hot months that they are not exposed unduly.

Epilepsy is one of the most common of the sequelæ and occurs in various degrees of severity from slight epileptiform convulsions to the severest forms of the disease. Mickle (b) is of opinion that the apoplectiform seizure or epileptiform *petit mal* of general paralysis has been mistaken for sunstroke, and in support of his views he states that he has seen some cases with severe extensive brain-lesions of general paralysis. Maclean (a) observed that immense numbers of soldiers were invalidated home from India for this affection following sunstroke, but in a large proportion of the cases the attacks disappeared before arrival at Netley, particularly in the long voyage round the Cape of Good Hope. As a rule, the disease seemed to be amenable to treatment. The same author also noted a few examples of chorea-like movements of the muscles of the forearm and hands, probably due to nerve irritation. The frequent occurrence of epilepsy is suggestive, and, as in the cases of the periodical psychoses, of which I have given several examples (b), the disorder seems to be a manifestation of an unstable vaso-motor state.

Both idiocy and imbecility may be dependent upon early epilepsy, but the absence of spastic symptoms, contractures, strabismus, and other deformities, together with the absence of progressive deterioration associated with the occurrence of the convulsions, are in my opinion characteristic of the acquired type rather than the hereditary, and in cases of epilepsy following upon sunstroke, the mental defect and convulsions are collateral phenomena, both depending upon the same cause, whilst the positive signs of alienism, such as anomalies of character and moral perversions, with

defective or one-sided development of special faculties, all point to an acquired psychosis, in a large measure differing from the progressive deterioration of ordinary idiopathic or hereditary epilepsy.

In adults I have seen the occurrence of episodic attacks somewhat analogous to epilepsy in which there was a periodical attack of depression, or maniacal delirium, or even conditions closely resembling the maniacal, epileptiform and apoplectiform attack of parietic dementia.

Insanity arising from insolation is much like that due to traumatism, but as a rule, progressive deterioration terminating in parietic dementia is far more common in the latter than in the former. Insolation forms an acquired predisposition to insanity, and as in the cases of traumatism, the most serious psychoses are developed months, or even years, after the injury.

Earle's tables of 107 admissions to the Northampton Lunatic Hospital show that four were due to sunstroke. (a) In the York Asylum 7 out of 864 admissions were referred to the same cause. In Bethlem Hospital, out of 1,947 cases admitted, no less than 49 were attributed to sunstroke. Clouston believes that few Englishmen become insane in hot climates, in whom that cause is not assigned, and that sunstroke gets the credit of far more insanity than it produces. (b) He only admitted twelve cases in nine years which could be said to have been due to traumatism or sunstroke, being only one-third per cent. of the admissions. This, I believe, to be unusually low, but possibly the high percentage (2.4) in the case of Bethlem may be accounted for by the large numbers of officers and others admitted who have seen foreign service.

Mickle (c) is of opinion that sunstroke is not uncommonly a cause of general paralysis among British soldiers in India.

In the returns of the Commissioners of Lunacy (d) 94 (or 2.8 per cent.) of 3,374 male, and 3 (or 3 per cent.) of 910 female cases of general paralysis were attributed, or partly so, to sunstroke.

In 60 cases of general paralysis Meyer (e) found three from sunstroke, and he endeavoured to distinguish clinically the cases following insolation from those following exposure to other great heat.

Victor (f) has described several cases apparently of general paralysis due to exposure to excessive heat in a gun foundry. Berstens (g) has published similar cases. Calmeil declared that exposure to great furnace heat was a cause of "polypharésie" and was frequently seen in labourers in iron-works, rolling mills, &c.

General paralysis is said to be rare in hot climates but it is an old observation that this comparative exemption does not extend to new comers. (h) I have only seen one case of general paralysis with a history of sunstroke, and in this case the symptoms and pathological appearances were by no means conclusive as to the nature of the disease, whereas the number of cases simulating general paralysis has been remarkable. In no less than twenty-two of the cases tabulated the symptoms consisted in associated mental and motor defects, which rendered the differential diagnosis one of extreme difficulty. They mostly had physical symptoms, such as tongue tremors, thickness or slurring of speech, inequality of the pupils, altered reflexes (chiefly exaggerated), shaky and interrupted handwriting, tottering or weak gait, loss of control over bladder and rectum, hallucinations or perversions of all or some of the senses (most frequently of sight, hearing, and taste), and mental conditions, such as

melancholia, hypochondriasis, but more commonly exaltation, extravagance, excitement, and even acute mania. With such a combination of symptoms the diagnosis was apparently simple, but most of the cases proved deceptive, for after a time the physical signs disappeared, leaving, however, the mental health in a weak and permanently impaired condition, as shown by some childishness or simplicity, or perhaps irreluctancy or inattentiveness, or more commonly by smiling, pleased, self-satisfaction, and a trace of fixed expansive ideas.

Such patients are tractable, docile, useful, and industrious, and are perhaps able to resume work, and so they may go on for many years with no return of the motor symptoms, no special sensory disturbances, and no marked change in the mental state from year to year.

A very common symptom is cephalalgia (*a*), which may occur periodically or persistently, and probably depending upon chronic meningitis, with some thickening or opacity of the membranes, these patients cannot tolerate heat, and a close or heated atmosphere will cause an exacerbation of the sensory symptoms, or even a recurrence of the mental disturbance. Alcohol is also apt to aggravate the symptoms, just as in cases of traumatism. In several cases perhaps alcohol played a considerable part in the production of the insanity; but this was possibly owing to the readiness with which alcohol disturbs a brain previously weakened by sunstroke. Where this happens the primary affection usually leaves no immediate mental or physical defect; but, nevertheless, it forms a predisposition to the disastrous effects of other exciting causes, such as alcohol, &c.

The symptoms of bromide poisoning, plumbism, locomotor ataxy, and tabes dorsalis, acute ascending paralysis, acute, chronic, or more or less generalised palsy, generalised or diffuse paralysis or ataxy following acute affections, epilepsy, senile dementia, disseminated sclerosis, and brain tumours, all may tend to complicate the task of differentiation. The greatest difficulty, however, is experienced with such affections as general paralysis of the insane, syphilitic disease of the brain and membranes, alcoholic insanity, dementia, with paralysis from local lesions, or circumscribed cerebral lesions with dementia, and paralysis due to softening, hæmorrhage, embolism, or thrombosis. There are few motor, sensory, or mental features which can be regarded as characteristic of sunstroke; it is rather by the history of the case, and the consideration of all the details, that a diagnosis can be made.

The pathology of the affection is somewhat indefinite. Many writers uphold the view that exposure of the uncovered head to the scorching rays of the sun may give rise to purulent meningitis; but the question may be asked, why, when so many people are exposed to the injurious influence, so few suffer from it? The difficulty in answering this question is increased by the want of a satisfactory physical explanation of the fact. Obernier (*b*) has endeavoured to show by both clinical and experimental observations that the cause and nature of sunstroke are to be sought in the abnormal increase of temperature in the body, and Liebermeister (*c*) has further shown that the cerebral symptoms associated with high temperatures are only to a limited degree, if at all, dependent upon cerebral hyperæmia. With due regard to the observations of these writers, there is some probability that at the onset of the symptoms there is some hyperæmia of the pia and brain, or, more accurately speaking, a distension of the whole venous system with, may be, cedematous infiltration of the brain substance, and the changes found after death may further assume the

existence of a cerebral congestion similar to the congestion found in other organs. Enough facts are not yet established to justify any decided opinion as to the pathology, and accurate anatomical investigations in the various stages are much required.

Experiments have shown that moderate heat, directed upon the cranium, causes dilatation of the vessels, and we must conclude that the initial congestion of sunstroke is due in part to heat. Buck (*a*) is of opinion that a tendency to capillary stasis is induced, the heart labours to overcome the obstruction, and failing, gives us the syncopal or cardiac variety; or the nervous system, resenting the increased abnormality of the circulation, develops convulsions and coma as the cerebro-spinal variety of the disease.

The post-mortem appearances vary according to the form of the disease. In ardent fever, serous effusions in the ventricles and between the membranes of the brain have been noted (*b*) with turgescence of vessels and congestion of the pulmonary system.

The cause of death is said to be most commonly due to asphyxia and not to apoplexy, and the most important changes are found in connection with the thoracic viscera. (*c*) When the medulla is affected, accumulation of blood takes place in the right side of the heart and lungs, with, secondarily, as a consequence, a want of that fluid duly arterialed in the brain. Roth and Lex (*d*) state that death in the majority of cases occurs from cardiac paralysis and only occasionally from cerebral disturbance. Arndt (*e*) speaks vaguely of a "diffuse encephalitis" as explaining the cerebral symptoms which often remain after the acute attack. The same author points out that the blood is acid during an attack of insolation, is very rich in urea and white globules, and shows very little tendency to coagulation. Köster (*f*) and Fox (*g*) have called attention to the occurrences of hæmorrhages in the superior cervical ganglion, and the former found hæmorrhages, separation of the nerve fibres and extravasations in both vagi and phrenic nerves. In one case (Dr. Shuttleworth), there was found after death, meningitis with effusion and traces of old standing disease of the membranes. In another case (*h*), there were no effusions, but the membranes were thickened and somewhat opaque more especially at the vertex.

In one case I found marked opacity of the arachnoid with an excess of serous fluid between the convolutions and in the ventricles. The dura mater was apparently healthy and non-adherent to the skull cap. The inner membranes stripped readily, and in one coherent film, leaving the surface of the convolutions intact. The vessels at the base were healthy and normal in arrangement. There was no marked congestion of the nervous system. The convolutions themselves were well formed and the cortex was of good depth and colour. Striation, however, was ill-defined and throughout the white substance of the brain there was a "water-logged" condition. On microscopic examination of the cortex cerebri, I found a considerable number of spider cells in the interstitial substance and these were by no means confined to any particular layer of cells. The presence of these spider cells is common in general paralysis of the insane. Although by no means special to it Mickle (*h*) has observed them in chronic local syphilitic cortical cerebritis; and in connection with local destructive, and in parts, slightly indurative, changes following traumatic (*i*) cranial and cerebral damage.

The absence of adhesion of the pia to the cortex, and

 (*i*) Popoff "Virchow's Arch.," xiii, 421, and "Centralblatt," No. 33 1875.

the presence of the spider cells is not at variance with the view of Mendel (a) that by the pathological swelling of the spider cells, increase of nuclei and of formed intercellular substance, the outermost layer of brain-cortex is swollen. Simultaneously, dilatation of vessels exist in the pia, and hindered circulation, and from this condition of pia and cortex the space normally existing between them is obliterated, and the friction between pia and cortex leads to exudation, and nuclear proliferation in the pia, which last passes into and incorporates itself with the cortex; a condition favoured by the belt work resulting from increase of the intercellular substance.

Undoubtedly, the densely matted network of scavenger cells (b) which pervades the upper or outermost region of the cortex immediately under the pia may remind one of the increase of connective tissue passing along Glisson's capsule in a sclerosed state of the liver, but the presence of spider cells in the cortex does not invariably imply obliteration of the epicerebral space or adhesion of the outermost layer with the pia.

In another case which was diagnosed as general paralysis, the dura mater was found normal, no pachymeningitis, great excess of subarachnoid fluid all over the surface of the brain, especially marked over the upper ends of the ascending frontal and parietal convolutions. Pia mater, sodden and thick, but peeling readily from the upper surface of the brain leaving the convolutions intact. The convolutions were somewhat thin, arteries at base slightly atheromatous, pia mater at base peeled readily and did not tear the surface of the convolutions. On section the grey matter was pale and ill-defined, especially over the whole of the frontal region. Left lateral ventricle somewhat dilated, right apparently normal, no sign of disease in ganglia at base, pons and medulla apparently normal, white substance of brain soft and pale, the spinal cord was interesting, the dura mater was distended by fluid in its lower parts, whilst along the cervical and chiefly dorsal regions there were numerous hæmorrhagic patches on its outer surface consisting principally of clotted blood lying in the meshes of thin gelatinous material, no lymph or actual inflammation of the membranes. In the lower cervical region the anterior surface of the dura mater was adherent to the posterior surfaces of the bodies of three cervical vertebrae by old firm adhesions. No compression of cord and no caries of bone could be detected. The cord itself was firm and healthy and did not show any signs of degeneration. Köster (c) has described a hyperæmic condition of the brain, the occurrence of several small ecchymoses under the pependyma of the left ventricle, infiltration of the lower lobe of the right lung and also ecchymoses under the peri and subcardium of the left ventricle." The same author, however, has seen similar results in the case of a syphilitic woman where excessive increase of temperature could not have been the cause of death, and he further calls attention to the possible occurrence of disturbances of the vasomotor and respiratory nerve centres which must take place in a pronounced form in patients suffering from sunstroke. The inner membranes were easily stripped from the convolutions. There was a slight excess of cerebro-spinal fluid; the white substance of the brain was œdematous and gaped on section; otherwise, beyond considerable injection of the choroid plexus, the brain was fairly healthy.

Hitherto, I have endeavoured to bring before you some of the more difficult problems of diagnosis arising in connection with heredity and bodily illnesses. Although I have made use of some material which may be considered old, I feel that the importance of the subjects renders occasional repetition desirable.

EXCISION OF OSSICLES AND MEMBRANE IN CHRONIC SUPPURATION OF THE MIDDLE EAR.

By RICHARD LAKE, F.R.C.S.

OPERATIVE treatment on the mastoid, in otitis media suppurativa chronica; has come very prominently forward of recent years, and it is with a view of pointing out the mean, which exists between the antiseptic local treatment of the ear, and the operation of opening the mastoid antrum (letting alone those far more serious operations on the lateral sinus, or for otitic brain abscesses which do not come within the list of methods of treatment of the above diseases), that this paper is written.

The occasions for removal of the diseased structures in this complaint are: (1) The cure of otherwise intractable suppuration. (2) Improvement of the hearing power. (3) A minimising of the risk of intracranial complication. (4) As a substitute for mastoid operation. From a consideration of these points, especially the first two and last, the exact indications for operative, and successful operative procedures should result.

I would like to remark at once, that save in the exceptional circumstances which will be pointed out as we proceed, no operation should be attempted unless the suppuration is of over three months' standing, and has resisted antiseptic treatment carefully carried out for that time, or unless the discharge is for ever recurring.

For the cure of this disease, it is necessary not only to remove polypi, granulations, and sequestra, but, and in this lies the key to the value of the operative treatment, also to supply efficient and free drainage; it is precisely in cases in which the perforation is high up in the membrane that the operation is most useful, for instance, in Shrapnell's membrane, in the posterior superior quadrant. For although these two points are both at the lower part of the attic, yet we know unfortunately that true basal drainage rarely obtains here, and that the irregularities and divisions of the attic, its inaccessibility to antiseptic irrigation, cause the contrary really to be the case. Neither in the remaining cases, those in which the two large ossicles are partly destroyed, and their bodies alone, with more or less of the membrane remaining, is drainage free for the semi-necrotic ossicles are partly shut off from the exposed cavum by cicatricial tissue, pus percolating through its meshes.

With respect to necrosis of the ossicles, it has been said, and I think rightly, that the malleus alone is rarely affected; but when one ossicle only is affected it is usually the incus, naturally, there is no regular rule for the extensive destructions of membrane which are accompanied by destruction of the handle, and sometimes exfoliation of the incus, so that when excising the malleus the incus should be sought for.

But by removing the ossicles and membrane we have not in all cases finished our work, for a study of specimens, and published results, will show that a large proportion of these cases are not really cured by these proceedings even in the large perforation cases with long-standing suppuration, since in these, as previously stated, the attic and antral orifices are not infrequently obstructed by a mass of cicatricial bands or webs with caseous pus and detritus ready to take an active septic development from suitable stimulation; as a result of this condition it behoves the operator to remove with curettes all the tissue from these regions, and to combine this with a careful irrigation with an efficient

(a) Mendel, Med. Soc. of Berlin, Feb. 14, 1888.

(b) Bevan Lewis, "Manual of Mental Diseases," p. 523.

(c) Köster, *op. cit.*

antiseptic, after using hydrogen peroxide. I believe that if this be done carefully in suitable cases it will frequently obviate the necessity of the mastoid operation, though if after this has been done suppuration continues the major operation is clearly indicated, and should be done without hesitation. It is also probable that a removal of the anterior attic wall would be advisable in many cases.

Now with regard to the improvement in hearing; after this operation no one who has performed this operation with a sensible appreciation of its objects, can fail to have been struck by the usual marked improvement in the cases so treated over those which have been quieted down by a long and often tedious treatment of antiseptics, when from one cause or another more radical measures have not been possible.

The acoustic functions of the organ are always adversely affected in the latter, often indeed to a point of absolute suspension, with a probability of ultimate destruction, together with the permanent risk of intercranial disease, or a recurrence of the distressing discharge. By an intelligent appreciation of the aim of this operation is meant the recognition of *all* the objects in view, that is to say, the *whole* membrane must be removed to obtain the happiest results in the improvement of hearing. The object being to expose the stapes, and not to have it covered by a piece of useless *membrana tympani*, which will most probably later on form adhesions, thus still further preventing sound waves reaching the stapes direct.

Operation.—The most efficient antiseptic irrigation of the canal should be performed with a cool unirritating lotion (not a hot one), in order not to cause unnecessary relaxation to the vessels; also irrigate the attic, if open, by means of Hartman's cannula.

The ear is then packed with wool soaked in cocaine hyd., 20 per cent., and left for five minutes, even if general anaesthesia is used. Commence the excision by dividing the membrane at its attachment to the meatus, taking care that this circumcision is complete, a probe will demonstrate this. The tendon of the tensor tympani and the anterior ligament next require division; the membrane is then seized with forceps, snare, or extractor, and together with the malleus is dragged down and out. Haemorrhage during the operation is to be checked by cocaine and pressure.

It is usually the extraction of the incus which gives most trouble, but a crotchet-shaped curette will usually extract it, or an incus hook may be used, but the incus is in difficult cases only a remnant. Haemorrhage is sometimes very troublesome and persistent, but if this is so, patience will eventually conquer it.

Crotchet-shaped curettes should be used to clear out the attic thoroughly.

General anaesthesia is not necessary if the patient has sufficient self-control to keep still; moreover, I think that it increases the bleeding on account of the posture of the head; again, it is certainly less easy to operate with general anaesthetics than with cocaine alone.

During the operation there are certain details which should be remembered in this operation; and one is not to cut the corda. In order to avoid this, great care is often required, indeed, it would in certain instances seem impossible to avoid doing so, for instance, in those cases in which the nerve either runs an abnormal course or is adherent to the membrane at the usual level. As a general rule, however, if when dividing the membrane at its posterior attachment care is taken not to have more than just the point of the knife through the membrane no accident will happen. The corda lies about 1-32nd of an inch beneath the membrane.

The second point is the necessity of dividing the anterior ligament of the malleus as well as the tendon

of the tensor tympani, and this is most easily done with a rectangle tenotomy; this is passed upwards anterior to the head, its division being made by a forward and outward cut.

A third point is the division of the long process of the incus or the inco-stapedial joint. Experience shows that quite as frequently as not this is not necessary, not only because the joint usually gives way when the incus is pulled on, but because in long-standing cases the long process is frequently destroyed wholly or in part. If the points above mentioned are adhered to the whole strain of the pull on the malleus is transferred to the incus, and the latter bone will often come away also.

The following unsatisfactory results may ensue:—Continuance of the discharge in spite of treatment, requiring the opening of the antrum. Transient vertigo is of no special importance, on account of its temporary character. But a more objectionable sequel is the formation of false cholesteatomatous masses in the attic, as has been reported by numerous observers, though I have not seen it myself; there would be no particular difficulty in cleaning it, though it would probably recur, and is usually present before. The malleus may break off short, if it does the effect of treatment may be tried before further operation, as the whole trouble may have been in the neck of the bone. Section of the corda: this causes paralysis of the sense of taste on the same side of the tongue, in its anterior two-thirds, with a sense of numbness over the same region. This never lasts for more than two months. Transient facial palsy may occur if energetic curettage of the tympanum is required.

As in this paper other than suppurative conditions are not under consideration, I shall not touch on the other diseases, for the relief of which excision of the ossicles and membrane has been brought forward lately.

The following suppurative conditions are, in my opinion, sufficient to justify operation; if careful treatment has failed to stop the discharge when consistently carried out for a period of from six weeks to three months, or if, the treatment being successful, there is great impairment of hearing, with good bone conduction, and the stapes not visible:—

1. Perforation in *membrana Shrapnelli*, with definite evidence of caries and deafness.
2. Perforation over *foramen ovale*, *i.e.*, in posterior superior quadrant.
3. Large perforation in the inferior half of the membrane, or including the whole membrane.
4. Perforation of the M.S. with destruction of the anterior attic wall and disease of the ossicles.
5. When there is evidence of caries of the inner tympanic wall, as evinced by lateral vertigo, &c., on syringing; dizziness alone being usually the effect of pressure on the stapes.

Clinical Records.

CANCER HOSPITAL, BROMPTON.

Haemorrhagic Cyst of the Ovary filling Pelvis—Accompanied by Adeno-Carcinoma of the Uterus—Pan-Hysterectomy and Removal of Cyst and Appendages—Recovery.

Under the care of MR. FRED. BOWREMAN JESSETT, F.R.C.S.

A. C., *Æt.* 43, married, was admitted under my care complaining of bleeding from the vagina. Has always had good health. She had had six pregnancies, and three

children, the last being three to four years ago. The youngest child is ten years old.

History.—Up to two months ago patient had always been quite regular and natural, but since then there had been almost continuous bloody discharge per vaginam. Has not missed any period, nor was there any increase in the amount of blood lost at the previous periods.

During the earlier part of the time there was some intermittent abdominal pain, but lately has had none.

Present Condition.—Patient is anæmic with pallid lips and pearly conjunctivæ. By abdominal palpation there is found a round, hard, fixed swelling occupying the left iliac and hypochondriac regions. The limits of the swelling cannot be determined with any degree of accuracy.

Per Vaginam the cervix is found to be high up and pointing forwards, but normal in appearance and to the touch, excepting in the posterior lip which is rather hard. The os is papular and admits the finger tip. There is a large hard mass, semi-elastic, situated in Douglas's pouch and projecting into the posterior fornix. This swelling is continuous with the swelling felt in the abdomen, the whole mass is very slightly mobile and attached to the uterus. Digital examination caused slight bleeding.

On December 31st the patient was examined under ether. The fundus uteri was then found to be firmly adherent to the mass. The os was high up behind the pubes. The mass was found to be fairly mobile. The uterus sound passed $4\frac{1}{2}$ inches. After consultation it was decided to perform an exploratory operation, the diagnosis being soft rapidly-growing myoma of uterus.

On January 7th, the vagina having been kept douched with hyd. perchl solution, 1-3,000, and cotton-wool tampons soaked in 1-5,000 hydr. perchl. solution, with the assistance of my colleague, Dr. Purcell, I performed the following operation.

On opening the abdomen, it was found that the tumour was firmly adherent to the sigmoid flexure and filled the pelvis. With some difficulty, the adhesions were separated which fixed the growth to the pelvic peritoneum. On passing my hand down on the left side, I tore through the cyst wall, and a large quantity of dark, almost black, blood clot escaped. By degrees, I separated all adhesions, and then peeled the cyst off the posterior surface of the uterus, ligatured the ovarian arteries on the left side, and divided the broad ligament. The right ovary was then examined and found to be much enlarged, and containing a cyst the size of a large walnut, filled with dark blood clot. This ovary was firmly adherent to the cyst on the left side, and as you see by the specimen, this was the point I tore through when separating the adhesion. It became a question, then, whether to remove the cysts and appendages and leave the uterus, or to remove that organ. Being guided by the history of the case, and the enlarged condition of the uterus suggesting possible malignant disease, and also to some extent by the fact that the cyst which in the first instance suggested possible tubal pregnancy, had been so adherent to the posterior surface and to the whole of the pelvic peritoneum, I thought the patient would be in a better condition if the whole organ were removed, and free drainage arranged for through the vagina. I therefore proceeded to perform pan-hysterectomy in the manner I have so recently advocated here, leaving a glass drainage tube in the vagina, and packing wound with iodoform gauze. The patient made an uninterrupted recovery, was up in three weeks, and leaves the hospital on Saturday. The Pathologist has furnished me with a report of the specimen whereby my decision to remove the uterus is thoroughly justified. Mr. Plimmer says "A section from the uterus presents the characteristics of malignant adenoma, the tissues being infiltrated by atypical gland formations. The wall of the cyst is composed of fibrous tissue, with irregular bands of unstriped muscle arranged without any order, so that the section shows these bands cut obliquely in all ways, longitudinally and transversely. The interior is lined with epithelium, which is arranged in papillary processes. The sections of the cyst show no sign of malignant growth, being apparently formed of disorganised ovarian stroma tissue."

Transactions of Societies.

BRITISH GYNÆCOLOGICAL SOCIETY.

MEETING HELD THURSDAY, FEBRUARY 13TH, 1896.

The President, CLEMENT GODSON, M.D., in the Chair.

SPECIMENS.

MR. F. BOWREMAN JESSETT showed two specimens:—

(1) Hæmorrhagic cyst of the ovary, filling the pelvis, accompanied by adeno-carcinoma of the uterus, pan-hysterectomy, with removal of the appendages, which will be found in another column under the heading "Clinical Records."

(2) Case of advanced uterine carcinoma, treated by chloride of zinc paste. Recovery.

The author was induced to show this specimen for the following reasons: First, because the patient was first seen by the President, being sent to him by Dr. Chambers; and the President had asked him to see her and perform the operation. She was 74 years of age, highly nervous, and suffered from heart disease; and it was therefore thought that she could not bear the shock of vaginal hysterectomy. After scraping away as much of the disease as possible with a Volkmann's spoon, he applied the dredger, and then packed with chloride of zinc wool. The slough came away on the tenth day. Secondly, he showed the specimen as illustrating how difficult it was in some cases to avoid the accident of a slough into the rectum. For, in this case, a fecal fistula occurred; ten weeks after the operation, however, this had quite healed. Thirdly, the specimen supplied an answer to the question whether the peritoneal covering of the uterus shared in the process of sloughing. In this case the peritoneal reflections, both in front and behind, could be plainly seen on the specimen.

The PRESIDENT said he was very gratified to see this specimen. The patient was the mother of a medical man; and when she learned from her own medical attendant, Dr. Chambers, that she had malignant disease, she was greatly distressed. But, having in view the operation performed by Mr. Jessett, he felt that he could hold out to her hope of recovery. Formerly such a case would have had to go unrelieved. It was too soon to speak of permanent results; but meanwhile the patient was greatly relieved, her life was prolonged, and she had the hope that the disease was cured; and this result was a great deal in itself.

DR. PURCELL was still in doubt as to the presence of the peritoneum on the slough shown; he did not know whether the specimen had been submitted to the pathologist. The principal accident to be feared was sloughing into the rectum; and the risk could be minimised by applying sufficient bicarbonate of soda to neutralise the excess of chloride of zinc.

DR. HAYWOOD SMITH thought the technique of the caustic operation was most important. He would ask whether in this case the chloride of zinc wool was used too wet; it should be only damp, as advised originally by Sims. He thought the bicarbonate of soda should be applied next to the chloride of zinc, without the intervention of gutta percha.

MR. JESSETT, in reply, said that in this, as in other cases, he used a gutta percha cap, but inside it, next to the chloride of zinc wool he inserted some dry wool, which absorbed excess of chloride of zinc sufficiently to act on the lower part of the uterus. As an additional precaution he had lately adopted the further procedure of packing the vaginal walls round with lint covered with iodoform ointment. He had found that if the wool was too dry it had little or no effect, as it could not then be got strong enough. He used the paste in pellets which he packed in one at a time into the uterine cavity, and by this means the caustic was applied as dry as was consistent with efficacy.

DR. GEORGE ELDER, of Nottingham, showed two specimens: 1. From a case of supra-vaginal hysterectomy during pregnancy for threatened intestinal obstruction, full notes of which will be found on page 205.

2. A large fibroid, increased rapidly after marriage, in the discussion that followed.

The PRESIDENT thanked Dr. Elder for his interesting specimen, and asked him whether the symptoms were

such as to require immediate interference, or whether it would have been possible to allow the patient to go on to a later stage of pregnancy, a Porro's operation being then performed. For, though there had been obstruction, it was apparently relieved the day before the operation.

Dr. BANTOCK joined the President in congratulating Dr. Elder on the success of his case. He thought it was a serious step to question the judgment of a man who had a case like this to deal with, as he alone could have the knowledge necessary to guide him to a correct decision. For this reason he upheld Dr. Elder's action. The specimens illustrated very well the arguments he had repeatedly urged against intra-peritoneal treatment of the stump. The chief difficulty was hæmorrhage. For, at the time when hæmorrhage was likely to occur, they found that it did occur from the stump, in the extra-peritoneal method, however well controlled at the time of operation; and if the stump was inside the peritoneum, they had no command over the hæmorrhage. As a matter of fact, the intra-peritoneal method was now no longer performed by any operator of repute. It was largely replaced by the method of total extirpation, which was a form of extra-peritoneal procedure. His experience led him to regard this operation with favour; nevertheless, in view of the importance, in his opinion, of keeping the vaginal roof intact, he contended that the cervix should be left, when this was possible.

Dr. PURCELL did not gather whether Dr. Elder used a Keberlé's serre-neud; if so, could the hæmorrhage not have been controlled by it? He was glad to hear that Dr. Bantock had come round to the view that pan-hysterectomy was an extra-peritoneal procedure.

Dr. BANTOCK observed that he had always held this view.

Mr. BOWREMAN JESSETT congratulated Dr. Elder on his case, and remarked that statistics showed that, under such circumstances, removal of the uterus and tumour was the proper procedure. The only point in which he differed was that he thought it would have been better to remove the whole cervix, in which case there would have been no after-hæmorrhage. When the cervix was left, and the peritoneum laced over it, then, if hæmorrhage occurred, it formed a hæmatocele between the stump and the peritoneum, which would require interference. He contended that pan-hysterectomy did not weaken the vaginal roof; he had seen now many instances where the after-results showed the contrary. Moreover, the possible weakening was not to be compared in gravity with the weakening of the abdominal wall, with the tardy convalescence, and with the risk of abdominal hernia and fistula, which resulted from treatment by the serre-neud.

Dr. ELDER, in answer to the President's question, said that the fœtus in this case was dead; but had it been living, the patient's condition was so grave as to place her interests paramount, and, further, the nearest doctor lived seven miles away. His only regret was that he left the cervix, as otherwise the patient might have been spared both pain and risk from hæmorrhage. He did not use a serre-neud, but brought the peritoneum round the stump.

Dr. GEORGE KEITH read a paper on "The Permanent Cure of Antelexion," and Dr. ELIOT read some "Notes of Gynecological Cases," both of which we hope to publish in our next.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF ANATOMY AND PHYSIOLOGY.

MEETING HELD FRIDAY, JANUARY 24TH, 1896.

The President, Dr. JOHNSON SYMINGTON, in the Chair.

THE PRESIDENT, after expressing his thanks for the honour accorded to him by his election to the chair, formally declared the business of the evening opened. He then exhibited a pulmonary artery with four valves, all of which were well-developed, and of nearly equal size; two of them were somewhat more closely connected than the others. The President also exhibited, for Professor Cunningham (who was unavoidably absent), three puppies of the Cape Hunting Dog (*Lycan Pictus*), which were born in the Dublin Zoological Gardens, and explained their peculiarities.

STIMULATION OF THE PNEUMOGASTRIC NERVE.

Prof. PURSER made a communication on the stoppage of

respiration, which sometimes follows stimulation of the peripheral end of the pneumogastric nerve, and pointed out that this event may explain certain cases of sudden death, which are often attributed to primary stoppage of the heart: as in death resulting from a blow on the abdomen, or death from inhalation of chloroform.

Dr. FBAZER said he was the first person who administered chloroform in Dublin, and he never had a fatal case. He attributed his success to watching the respiration. He did not believe a right explanation had been given of the cause of death in fatal cases. The symptoms in those fatal cases mentioned were undoubtedly respiratory, not cardiac. He made it a point in the administration of chloroform to watch the respiration, and when the breathing became embarrassed, to stop the inhalation.

Dr. PARSONS gave the history of three cases which he said pointed to the conclusion that death from inhalation of chloroform was to be attributed to cessation of respiration rather than to stoppage of the heart's action. The heart, he said, may beat for a few minutes after the respiratory functions had ceased. He would like to know Professor Purser's opinion as to the effect of nitrite of amyl.

Dr. D. J. COFFEY, in discussing Professor Purser's paper, suggested that the fact that the inhibition of the heart, brought about by peripheral stimulation of the vagus, is not permanent, does not warrant the conclusion that a permanent inhibition cannot be determined by reflex excitation. In the latter case, powerful impulses roused in afferent nerves fall on the cardio-inhibitory centre, and the conditions are very different from those in peripheral excitation.

Prof. BIRMINGHAM asked if the author had in any of his experiments on animals, or in other cases, seen death due primarily to stoppage of the heart while respiration was unaffected?

Prof. PURSER, in replying, said it would be a dangerous condition of things if reflex impulses travelling along the pneumogastric could cause death by inhibition of the heart. He agreed with Dr. Coffey that a message sent down the vagi, from a reflex centre in the brain, might produce results very different from excitation of the peripheral portion of the cut nerve. He had never seen a human being die of chloroform. In a series of experiments on animals, where death took place from chloroform, he never found the heart stop before the respirations. He could not give Dr. Parsons any information on the subject of nitrite of amyl; he had never experimented on animals with the drug; he had, however, prescribed it in practice with satisfactory results. In reply to Dr. Birmingham, he said he had never seen such a case.

THE HOMOLOGUE OF THE DUMB-BELL-SHAPED BONE IN THE ORNITHORHYNCHUS.

Prof. SYMINGTON described the form and relations of the dumb-bell-shaped bone in the ornithorhynchus, based upon the microscopic examination of serial sections of the beak of this animal. He discussed the theory as to its homology, and considered that it corresponded to the mesial palatine process of the premaxilla of ordinary mammals.

THE TOPOGRAPHICAL ANATOMY OF THE PANCREAS, DUODENUM, SPLEEN, AND KIDNEYS.

Prof. BIRMINGHAM made a communication on the topographical anatomy of some of the abdominal viscera, which he illustrated by a plaster cast. The cast was prepared from a body in which the viscera had been previously hardened *in situ*, by the injection of a solution of chromic acid. The cast gave a very clear idea of the condition of the pancreas, spleen, duodenum, kidneys and supra-renals; it also showed particularly well what the exhibitor called the "stomach bed." The author remarked that in probably the majority of cases the stomach assumed, when empty, an attenuated pear shape, and rarely if ever became flattened, as often represented. The greater part of the stomach in this condition lay nearly horizontally with its long axis from behind forward, the narrow end bending to the right. He believed that during distension the enlargement was more in a direction forwards and to the right than downwards. The duodenum did not lie in a coronal plane as usually represented, on the contrary it is strongly flexed (moulded) round the right side of the vertebral column. He also pointed out that the descending duodenum lies not in front of the inferior cava, but to its outer side.

The PRESIDENT said they had reason to feel obliged to Prof. Birmingham for the great trouble he had taken in the preparation of his cast. He had spent, he said, some time in considering the positions and relations of the abdominal organs, and to acquire accurate knowledge in this respect was a matter of great difficulty. On these questions there could be no doubt but that the opinions of the older anatomists are extremely fallacious. He felt bound to protest against many statements in reference to the relations of the abdominal viscera, contained in text books. It was the duty of the anatomists, so far as lay in their power, to supply physicians with accurate descriptions of those viscera.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, Feb. 22nd, 1896.

TREATMENT OF HYDATID CYSTS.

M. DUPLAY read a paper at the meeting of the Académie de Médecine on the treatment of hydatid cysts of the abdomen, in which he recommended a free opening of the tumour and the complete removal of all the vesicles. Thus emptied of its contents and cleaned out, the walls of the cysts are sutured and returned into the abdomen; the operation being terminated by suture of the primitive incision. In one case a hydatid cyst of the liver, in which the author had put into practice this method, the patient was well in fifteen days.

ANEURISM OF THE BONE.

M. Péau called attention to two cases of tumours, styled aneurisms of the bone, which presented a certain interest. The first case was that of a man of 50, who for two years had been taken with recurrent hæmorrhage from a small pulsatile tumour situated in the centre of the palate. The loss of blood placing the man's life in danger, the speaker decided to operate. An incision was made from before backwards through the soft parts of the palate, and through the centre of the tumour. Immediately an enormous jet of blood followed, which the operator arrested with his finger. With the gouge he attacked the alveolar edge, and removed a large piece of the bone up to and including the central portion. The wound was treated in the same way as in resection of the maxilla, and the patient recovered without further difficulty. An histological examination proved the tumour to be an angioma.

The second case was that of a young American girl, æt. 14, who was suffering from an erectile tumour below the orbit. Dr. Péau circumscribed the tumour by a circular incision, and removed it piecemeal down to the periosteum, cutting across the large vessels, which ran in every sense over it. As the bone was not in any way implicated, it was respected. This was also a case of vascular tissue resembling in every way an erectile tumour. These two examples were interesting by the fact that they establish in an indisputable manner that aneurisms of the bone, though rare, have a real existence, and should not be confounded, as is frequently the case, with other vascular tumours such as sarcoma.

CYSTOTOMY.

At the Société de Chirurgie, M. Bazy read a report on a case of supra-pubic cystotomy performed on a man who had an enlarged prostate. It was that of a man, æt. 70, who had been suffering for six months previously from retention of urine, which catheterism relieved with the utmost difficulty. Finally, no catheter would pass, and cystotomy was performed, local anæsthesia being obtained

by cocaine. The bladder was found to be seriously diseased, and the patient only survived a short time.

In commenting on the case M. Bazy said that he would mention briefly the indications and counter indications of cystotomy. He applied generally to those affections of the bladder in which the element "pain" predominated and in those large prostates which bled a great deal. But even here the sound *à demeure* frequently arrests the hæmorrhage and should generally be tried first.

HERNIA OF THE OBTURATOR FORAMEN.

In an interesting *these*, Dr. Berger treated with much details a variety of hernia which is considered rare but which in reality is frequent enough when it is properly diagnosed. Hernia of the obturator foramen is met with more frequently in women than men and can be seen at all ages, but is more frequent after sixty years. There is no strangulated hernia so easily overlooked as the kind in question because the tumour is not always to be seen or felt, and also the symptoms are in general far less accentuated than those occurring in other portions of the body.

Hernia of the obturator hole has been confounded very frequently with crural or perineal hernia; however, the former was a pedicle, and its tract is above the horizontal branch of the pubis and internal to the vessels, while the latter is felt in the lower outlet and can be traced through the vagina. The situation of the obturator hernia is in the angle formed by the two branches of the pubis. Frequently symptoms of occlusion of the intestine exists, and it is a difficult point to distinguish between internal or hernial strangulation. The situation can be cleared up with care, a certain amount of swelling will be noticed on the inside of the thigh, vaginal examination will reveal sensitiveness of the corresponding region, and the sign of Romberg (neuralgia) may be considered as almost pathognomonic.

All hernia of the sub-pubic aperture should be treated by operation as soon as possible, either as a preventive measure or to relieve strangulation. The operation consists in an incision over the tumour at the origin of the thigh, care being taken not to wound the obturator artery. Laparotomy should be reserved until the surgeon was able to satisfy himself by minute research, that no hernia existed.

MANAGEMENT OF THE UMBILICUS IN INFANTS.

In an address recently delivered on the subject, Dr. Caseel made the complaint that the principles first made known by the pioneer labours of Semmelweis in the region of obstetrics had received a suitable application in regard to the umbilicus of the newly-born infant. This was, therefore, the starting point of most of the infective diseases of the newly-born. He then pleaded for a method of management more in accord with the science of the day, and in support of his claims gave a *resumé* of the work of Eröcs (Beobachtungen über Nabel Krankheiten und die von ihnen aus gehende Infection des Organismus), and also those of Ehrendorfer, of Innsbruck; also Doctor, Buda-Pesth, Rössing, of the University Women's Klinik, Halle, Schraöer, Franz Scherer, Hermer, and Almander Keilmann. The daily bath of the infant was looked upon as injurious, as by means of it proper mummification and desiccation of the cord was retarded or prevented. Out of 400 children who were not bathed, not one had a heightened temperature, whilst nearly 5 per cent. of those that were bathed suffered more or less from fever.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, Feb. 21st.

THE SPERMA AND SEXUAL GLANDS OF TUBERCULOUS INDIVIDUALS AND BACILLI.

In Virchow's Archiv. 142-1, Dr Jaecckh has an article on this subject, giving the results of an experimental inquiry. In five cases guinea-pigs and rabbits were inoculated with seminal fluid and testicular substance of tuberculous individuals. The experiments with seminal fluid succeeded three times, and those with the seminal substance once. When ovarian substance was treated in a similar way it succeeded three times in four experiments. The objection often made that the bacilli came from the blood, and not from the substances experimented with themselves, could not hold good, as in those cases in which admixture of blood was unavoidable the inoculation almost always failed. The young of tuberculous guinea-pigs were tuberculous in only one instance, and even in this case a positive result could only have been attained by inoculation of the membranes, and not of the fetus itself. In any case, the author claims to have succeeded in proving the presence of tubercle bacilli capable of development in the seminal fluid of tuberculous men.

TUBERCULOSIS IN GERMANY.

From a recent publication of Dr. Brumerfilds, we have some statistics as to the doings of tuberculosis in Germany. There die every year in Germany from 170 to 180 thousand people (according to Bollinger, 250,000) of pulmonary phthisis. Of every 1,000 deaths, from 105 to 107 are due to tubercle. Of 1,000 deaths in the first year of life, 10·8 are due to the same cause; from the 1st to the 15th year, 62 per 1,000; and from the 15th to the 60th, 322·2 per 1,000; in other words, of those who are most capable of earning a living, one-third die of consumption.

As regards Berlin itself, the picture is darker still. Of the deaths between the ages named, 15 and 60, 332·3 per 1,000 are due to tuberculosis. Amongst masons the rate is 382, whilst amongst stone-pressers and lithographers it is 446, amongst tailors and shoemakers it is 563, amongst bookbinders 574, amongst cigar-makers 598, amongst turners 610, amongst hat-makers 664, amongst furriers 678. Amongst the grinders of Solingen the rate is higher still, and reaches 783 per 1,000. The highest mortality from consumption is, however, reached by the stonemasons amongst whom, out of 1,000 deaths, 893 are due to pulmonary phthisis.

At the Society for Innere Medizin, Hr. Litten gave an address on

THE MICROSCOPIC EXAMINATION OF FRESH BLOOD.

He said that from the time he commenced practice he had examined the fresh blood of all his patients and had become convinced that these preparations afforded a truer and more correct indication than the stained preparations. He had shown such preparations in 1892 at the Congress for Medicine, and was astonished that those most in the habit of examining blood were ignorant of them. He had found two peculiar structures in the blood of many healthy and sick individuals there were peculiar cylinder-shaped masses, of a white colour, granular, and highly refracting, about four to six times the size of the red blood corpuscles. Their size seemed to preclude the possibility of their circulation in the blood as they could not pass through the capillaries. Investigation led to the conviction

that these bodies were formed from the so-called blood plates, and staining showed that the conviction was correct. These plates were present in the blood of every one either singly or in groups. They were present in many diseases, as in leucæmia, pernicious anæmia, in increased numbers. Such cylinders were not present in living blood but formed when the blood was placed on the object glass and covered, they might be looked upon as collections of blood plates.

He had also determined the existence of a second group of cylinders in fresh blood which were present in all cases without exception. These cylinders were not quite so highly refracting as the former group, they were not white, but bluish and not granular. The edges were partially indented. He had paid special attention to the No. 2 form of cylinder lately. A patient came under his care with numerous well-marked forms. He was intending to demonstrate them to his hearers the next day, and instructed his demonstrator to prepare specimens, but was not a little astonished to find no cylinders in them. When he prepared them himself later they were numerous, but they were as regularly absent when his assistants prepared the slides. The different results must be in the different methods of preparing the slides. The usual methods employed by the assistants was to place the cover glass perfectly horizontally on the object, whilst he himself gave a gentle pull on the object carrier, so as to have an exceedingly thin layer of the object on the slide. It was shown later that the cylinders were really produced by the physical action on the blood. He later on sought to detect the cylinder in the process of formation, and saw that on the first movement of the cover-glass the red blood corpuscles formed themselves in rows, the hæmoglobin was pressed out of them by the movement so that they became quite colourless, whilst the blood-serum had become coloured. There could be no doubt, therefore, that the cylinders were formed out of the red blood corpuscles. In the inquiry, however, a second query was answered, viz. the origin of the blood plates. A colouring matter was added that stained the stroma of the nuclei of the corpuscles, when the stroma of the pressed-out nuclei was seen in the form of blood plates. From the experiments, it was shown that the blood plates were not, as was assumed, decomposition products of white blood corpuscles, nor preparatory stages of red blood corpuscles, but decomposition products of the latter—stroma minus hæmoglobin.

At the Medical Society Hr. Gluck showed

A SERIES OF CASES OF SUCCESSFUL RESECTION OF THE HIP-JOINT.

The operations were performed at the K. K. Friedrich-Kinderkrankenhause. The first case was that of a girl of 9, who had congenital dislocation of the hip. After some trouble, a fairly good result was obtained, the shortening being reduced 2½ ctm. in a total of 9 ctm. The second case had been in hospital 15 months, and was a very serious one. Tuberculous disease was so extensive that the whole of the ileum was removed, the hip-joint resected, the marrow scraped out, and the way prepared for recovery in such a way that the femur found its support on the horizontal ramus of the pubes. The child could now not only walk, but hop about on the lame leg. In the third and fourth cases the results were also satisfactory. In the fifth case there was knee-joint affection that had been first treated on the conservative method. Synorrectionomy was performed later, the joint cleared out; it was then tamponnaded with iodoform gauze, and with the exception

of a little thickening of the capsule, the child was quite well.

TREATMENT OF HYPERTROPHY OF THE PROSTATE.

The question of the treatment of hypertrophy of the prostate by castration and by resection of the deferens is the order of the day. Numerous works have been published on the influence exercised by ablation of the testicles on the volume of the prostate, the majority of which pronounce in favour of the operation. But patients are not always ready to accept the mutilation, even though they may be advanced in age. In fact, consequently of this manifestation of *amour propre* surgeons are willing to resort to any other means which may tend to the same end. It is thus that the method practised by Prof. Helferich will probably be well received by both surgeon and patient. The operation consists in resecting on both sides the vas deferens. In ten cases in which he tried this method he witnessed a satisfactory result at the end of two months. Only two of the patients were put under chloroform, the remainder supported the pain without any effort. The *modus operandi* was as follows: the vas deferens was pinched up with the left hand, and the skin incised for an inch; with a blunt instrument the canal was isolated, drawn out the length of six or eight inches, torn off the epididymis, and excised. With a little dexterity the double operation lasts only a few minutes. The wound, treated antiseptically, is closed and covered with collodion. A suspensory bandage is applied, and the patient returns to his occupation. The effect was almost constant in all the cases, micturition was greatly improved, but only in a few instances was the prostate diminished in volume. Hr. Helferich does not pretend that resection of the vas deferens equals in efficacy double castration, but it frequently succeeds in improving sufficiently the condition of the patient, and as it is a benign operation it ought to be tried.

Austria.

[FROM OUR OWN CORRESPONDENT.]

Vienna, Feb. 21st, 1896.

INVESTIGATIONS ON FACIAL PARALYSIS.

DEXLER described to the K. K. Gesellschaft his experiments on a horse suffering from bilateral facial paralysis. The object of his investigations was to test the theory of ptosis; whether it was due to the firm covering of the bulbus, or downward pressure of the lid after paralysis of the face had been established, as many authors affirm; or whether the ptosis was due to other causes such as lagophthalmus. Dexler has always held to the later opinion and thinks he has demonstrated it to the satisfaction of others in his experiments, combined with the histological results. He opened the cranium of the paralysed horse, and reaching the foramen opticum, applied the electrode of a battery with a feeble current which caused all the oculo-motors to act promptly as well as the musculus levator palpebræ superioris, whose function was also intact. If ptosis were simply understood to be a suspension of the function of the muscles, and thus cause a drooping of the eyelid, the present facts must be abandoned to sustain such an argument. It is more likely that the action resembles lagophthalmus, where another set of muscles are more actively engaged, such as the retractor bulbi in case, and thus produce the deformity. Where

any improvement takes place in the facial paralysis it begins in the upper branches of the nerve of the horse, as in man.

The histological examination is in harmony with the above experiment. The oculo-motor nerve in all its branches and central ganglia were found perfectly healthy, while the trunk and branches of the facial nerve were seriously degenerated by an inflammatory lesion in the ganglion geniculi. The blood vessels were greatly dilated and infiltrated with leucocytes while the ganglionic cells had lost their processes and were difficult to colour. There was also an inflammatory lesion in the Gasserian ganglion. There was no injury or ear affection to account for the morbid lesion, and Dexler concluded that the ganglion geniculi had been originally attacked by some unknown affection.

ANTITOXIN.

Paltauf related the history of a horse in the Serum Institute that produces a fluid of 500 units per cc.m.

At the last meeting of the German Congress, Behring proudly affirmed that a serum could be obtained by newer methods that could be relied on containing 1,000 units in 2 cm. Paltauf affirms that the method has nothing to do with the strength of the serum, but, that it depends upon the individual animal. The animal in point is a six-year gelding which was received into the institute in December 1894. In March 1895, the strength of the serum was 125 to 130 units; in September, 140; in December, 170; and at the present time is 500, or in other words 0.0002 cubic centimetres of this serum is ten times the lethal dose. This animal has now produced six litres of toxin since its reception. He has other animals in the institute about the same age and under similar circumstances which seem to vary very little in strength, and he concludes that it is the animal and not the method that must be observed in order to regulate the strength of the serum.

GYMNASTIC TREATMENT FOR THE CIRCULATION.

Bum brought this subject before the Medical Club for discussion in the form of a long review of the different opinions held on the treatment of cardiac diseases. Massage, diet, drugs, and mechanical applications of different sorts had been tried and lauded in turn, but with almost hopeless success. There were three indications to be fulfilled in every method of treatment of the circulation which would make or mar the success of any plan adopted. These were: (a) To prevent the congestion of the venous system; (b) Reduce the resistance in the peripheral vessels in order to relieve the pressure in the left ventricle; (c) To strengthen the cardiac muscle.

To prove the necessity of mechanical gymnastics, Sadler's experiments were brought forward to show how the nutrition can be sustained. Sadler found that dogs kept at perfect rest had a nutritive power of 36.6 per cent., while those with more activity had 66 per cent. Congestion in the muscle is prevented by its own activity, a form of inspiration and expiration by its own contraction. More CO_2 is produced, showing that oxidation is greater and more heat evolved, as shown by Helmholtz. The CO_2 next excites the lungs, increases the respiration, and acts vigorously on the other parts of the organism.

Sommerbrodt has shown that the intra-bronchial pressure is reduced by exercise, hastens the activity of the heart, and expands the arterial blood channels, without raising the pressure, as shown by his sphygmographic experiments. Bum, therefore, recommended deep respirations, which aided the venous system, with

methodical muscular movements to relieve the resistance in the systemic circulation. To supply the purely gymnastic movements, the depletory form of massage, with stripping, and muscular kneading of the extremities and neck, with firm tapping on the thorax and back, to produce vibrations in the cardiac regions are potent agents in securing a restorative action.

PHOSPHORUS.

The "Obersten Sanitätärathes" had under their consideration this week the propriety of allowing matches to be made with yellow phosphorus. It is now proposed to make this practice illegal and to substitute the Swedish or red phosphorus in the manufacture of this commodity, although many industrial difficulties stand in the way; yet the number of deaths annually occurring from the abuse of this household article has excited alarm, and compels the enforcement of the use of a less dangerous substance in the manufacture of these matches. It was also considered that the red phosphorus would reduce the death-rate among the workers of the match works.

DENSITY OF POPULATION.

At the last sanitary meeting, the health of Vienna was discussed, and the death-rate of other large towns of Europe compared with it. The investigation only confirmed the preceding experience that density of population is an active factor in the death-rate, although the condition of the houses was much to blame. In districts where 2 per cent. of the population was located, 1·14 of the deaths occurred; in others, where 28·3 of the population resided, the contribution to the death-rate was 3·5 per cent. It was resolved to formulate a recommendation to the Government to reduce the overcrowded parts considerably.

TRACHOMA.

According to the official report trachoma is on the increase, more especially in the northern counties of the kingdom. The incidence is particularly high among the peasantry. The County of Trenesiner alone records 3,860 cases.

The usual causes of filth and over-crowding are assigned as the source of the increase.

THYROID GLAND AND MORBUS BASEDOWI.

Scholz in his experiments with thyroid tabloids in the healthy and morbid state measured the amount of elimination both before and after administration.

Before administration, the elimination was equal to the ingestion. On the use of the tabloids no change in the elimination of nitrogen took place, while in the healthy it was reduced, but did not disturb the balance as no reduction of weight took place in either case.

The phosphoric acid elimination was tenfold increased in morbus Basedowi, while it was only four times in the healthy. In both cases, during the administration of thyroid, more phosphoric acid was eliminated than taken in. This agrees with Roos' results, and bears out Kocher in his opinion that phosphate of soda is the rational treatment for morbus Basedowi.

Italy.

[FROM AN OCCASIONAL CORRESPONDENT.]

ROME, Feb. 21st.

MONOPOLY OF QUININE.

PARLIAMENT has decided from a humanitarian point of view to take over the sale of sulphate of quinine, which

henceforth will be sold in the tobacco and salt shops, put up in small packets containing 3 grammes of the sulphate of quinine, or 2 grammes of the hydrochlorate of quinine; each packet will cost 50 centimes, which is at the rate of 2 soldi per gramme. The monopoly is undertaken for five years, after which it may be removed. The action of the Government is a benevolent one. It is calculated that 16,000 Italians die annually from malaria, and that 3,000 parishes at present exist where no apothecary can be found.

It is thought that if quinine can be timely administered many of these lives may be saved and the death-rate reduced.

THE BLASTOMYCETES OF SARCOMA.

Roncali, who is acting under Prof. Durante, in Rome, affirms that he has found the same microbe as Sanfelice in sarcoma and adenoid carcinoma of the ovaries. It requires a specific colouring agent as it resists both acids and alkalis. The parasite is found both within and without the cell. When young, and without covering membrane, the protoplasm is chromatic; as it increases in age the membrane thickens and the colour recedes. This "Blastomyces" in the cancerous tumour is still awaiting confirmation, as many efforts by other investigators have failed to obtain this parasite.

The Operating Theatres.

UNIVERSITY COLLEGE HOSPITAL.

ARTHRECTOMY OF THE ELBOW.—Mr. BARKER operated on a middle-aged woman suffering from what appeared to be tubercular disease of the left elbow-joint, which had lasted for four years; there was tenderness and limited mobility; a year and a half ago an abscess had formed, which had been opened. At present the part presented a pulpy swelling more marked than usual, especially over the head of the radius. Mr. Barker said he thought nothing better could be done than to excise freely. He made a curved incision under the olecranon, the convexity of the cut being downwards so as to turn up an oval flap; the olecranon was divided by means of a chisel and hammer, and turned upwards; a little patch of granulation was found on the cartilage with a small hole leading into the bone for about an eighth of an inch. Finding, however, that the disease was mostly confined to the synovial membrane Mr. Barker decided to do an arthrectomy as for the knee, considering it better to try and save the bone, even in the event of having to perform a subsequent operation. He dissected off the synovial membrane very carefully and with a certain amount of difficulty, as it bulged down in some parts almost like a fatty tumour; he took it away in one piece, which, he remarked, was the best method, as then the surgeon could make sure of having removed it all. He said that if the joint healed up without the removal of any bone the result would be not only very rare, but also one very difficult to obtain, and one it was not often justifiable to attempt. He had never operated on a case exactly at the same stage as the present one, in which it seemed a pity to sacrifice any bone; there was only one spot round the head of the radius where the bone was at all affected, and this was at a point where the osseous surface had been in contact with the diseased synovial membrane; this spot he carefully scraped. The separated portions of the olecranon were then drilled and brought into appo-

sition with a silver wire, the knot of which was made on the outside, in order to be out of the way of the ulnar nerve; the nerve had been recognised at an early stage of the operation and carefully held out of the way. There was very little bleeding, although no Esmarch was used; the bandage, as Mr. Barker pointed out, being very convenient for the surgeon during the operation, but giving rise to interminable oozing when taken off. He said that the elbow was admitted by all to be a joint lending itself but very little to arthrectomy, but as the cartilaginous surfaces were left fairly sound in the case he had just done, thereought to be a good chance of recovery with movement; a new synovial membrane would form, or at least, something which took its place. Of course, for a successful result it was necessary to have union by first intention. He considered that surgeons do not really yet know how far they can go in resections, as it is only of late years that it has been possible to carry out arthrectomies; it was wrong, he thought, to dogmatise. After the original incision had been closed the limb was dressed, but no splint was put on, for the arm was to be moved as soon as the patient liked; no passive movement causing pain was to be employed as it is apt to excite reaction leading to consolidation of the tissues and ankylosis.

ROYAL FREE HOSPITAL.

REMOVAL OF A PORTION OF A NEEDLE AFTER ITS LOCALISATION BY MEANS OF THE NEW METHOD OF PHOTOGRAPHY.—Mr. BATTLE has recently had an interesting case under his care in which the advantages of the new method of photography were strikingly illustrated. The patient was a young woman, *æt.* 30, who, nine months ago, ran a needle into her thumb, and had broken it off, leaving a portion in the thumb. She had suffered pain in the part at the metacarpo-phalangeal joint, and had been unable to use it properly since. Examination showed a small scar over the outer side of the joint named, and this was stated to be the spot at which the needle had entered, and at which an attempt had been made to remove it some months ago, but unsuccessfully. There was no abnormality to be felt, but the patient said that this spot was tender to pressure, and movements of the joint, especially those of flexion, caused pain. It was not possible to localise the needle, so Mr. Battle suggested that a photograph should be taken by the new method in order that if possible exploration might be undertaken with some prospect of success. Mr. Rowland kindly did this, and the result of the photograph showed the presence of a piece of needle lying across the joint at right angles to the long axis of the thumb, but it could not be told from the photograph whether the needle was in front of or behind the joint. From the position of the scar and the character of the pain Mr. Battle concluded that the foreign body was in front of the articulation, and so he made an incision in this situation, the incision being placed between the points of insertion of the abductor pollicis and the opponens pollicis; this incision immediately came upon a small bead of granulations in the middle of which could be seen a black speck, evidently one end of the broken portion of the needle. It was readily withdrawn with dissecting forceps. It was, as had been indicated by the photograph, probably just on the edge of the joint; it presented the usual black discoloured appearance of such bodies after they have remained for some considerable time in the tissue. The needle was about half-an-inch long and consisted of the half portion containing the eye. As a rule, Mr. Battle remarked,

when a needle is buried in the hand it is possible to find some indication of its presence, such as a hard localised point of resistance under the skin, but sometimes its position is by the side of a tendon or under some process of fascia so that it cannot be felt in the way mentioned; it appears, he said, that the new method affords a means of diagnosing such hidden bodies, whereas previously surgeons had to fall back on an electrical apparatus to indicate the actual presence of the foreign body. By this new process not only is the presence of the foreign body proved, but its relationship to the bones and the direction in which it is lying are fully shown. The body in the present case would have been very difficult to localise without this process for it was placed between the two bones and covered over by the tendons going to their insertion in the phalanx beyond.

WEDNESDAY, FEBRUARY 26, 1896.

IS SURGERY A CURE FOR CANCER?

In discussing the question of the results of the surgical treatment of cancer, probably most surgeons will be prepared to admit that it is inexpedient to place too much reliance upon the statistics belonging thereto, for a little reflection must show that a collection of figures alone cannot, in this instance, afford any trustworthy indication of the true value of the treatment. In the first place, it is obvious that several causes must be concerned in rendering these results either

favourable or the reverse. For example, the statistics may only apply to a series of selected cases, and no demonstration is needed to point out that when this is the fact the results must show a better record than in the cases in which selection has not been made. Again, it is essential to bear in mind that surgeons are sometimes called upon to operate upon patients who are practically far beyond the aid of surgery. Such patients, knowing full well the fate which is in store for them, and overwhelmed with despair for the haplessness of their condition, will, nevertheless, sometimes earnestly entreat the surgeon to make some attempt to afford them relief. Thus, if out of common humanity the surgeon consents to operate, he is bound to include the results, whatever they may be, among his statistics. Perhaps, then, a sense of duty and a feeling of compassion for his hapless patient, impels him to do that which is certain to affect his statistics unfavourably. A further point, however, may be mentioned in connection with this aspect of the subject, and, that is, that it is not fair to pass an adverse judgment upon the results of the operative treatment of cancer based upon a generalisation of those results. Let any one who is disposed to do this reflect for a moment, how cases of cancer vary, not only in regard to their accessibility and fitness for surgical interference, but also in respect to the period during which the disease has persisted before the patients come under the notice of the surgeon. Regarding the modern theory as the correct one, that cancer is a local disease, it is indisputable that the earlier a malignant growth is diagnosed and removed the better are the prospects of a good result following. In order, therefore, to make the statistics of the surgical treatment of the disease even trustworthy in this respect, it would be essential for the cases operated on to be limited to those in which the growths had only been noticed, say, for a period of three months. But even then some element of uncertainty would exist, for experience commonly teaches how the degree of malignancy of cancerous growths varies. In some patients the neoplasms progress at a slow rate, even at the time of life when the reverse might reasonably be anticipated; in others, on the contrary, the growths develop with a rapidity which presages a speedy termination of life despite the interference of surgery or the resort to any other procedures which the science of the day could suggest. Thus it must be conceded, that the statistics of the results of operations for cancer are to a large extent not adapted for the purpose of generalisation. It might, however, be urged that this argument could be applied with the same force to all operations in surgery, and that in any given series of cases requiring the same operative treatment the conditions will vary just as they are found to vary in cases of malignant disease. For example, the varying conditions present in cases of ovariectomy might be quoted in support of this statement. But we submit that a little reflection will show that cases of malignant disease stand in a category by themselves, inasmuch as one element is common to them all, namely, the assemblage of those features by which each case is endowed with a gravity not present

in any other pathological condition. But to take a gloomy, pessimistic view of the surgical treatment of cancer, as has been done by some surgeons, and to question whether the advanced surgery of the day is justifiable in this connection, is by no means warranted by the facts. At no time have the results of surgical interference in these cases shown so good a record as in the present day. It should be borne in mind, moreover, that many operations are now practised, under the ægis of antisepticism, and much relief for the patients gained, which in earlier days would have been impossible. To compare, therefore, the results of Brodie and the surgeons of former times with those obtained by modern surgeons, is practically useless. Nor has the Hippocratic saying that "It is better not to treat those in whom occult cancers have been formed, for when treated, they soon die, but if not treated, they live a longer time,"—much value in the present day. Contrast, for a moment, how a contemporary of Hippocrates would have proceeded to deal with an "occult cancer." What other result could be expected to follow than the speedy death of the patient? But as Hippocrates has been appealed to in the matter, it may be observed that his are not the only aphorisms which should be pressed into service when debated points in medical or surgical treatment are under discussion, and especially so far as the present subject is concerned, we would suggest that the following statement more truly represents the position of affairs, namely that "it is the duty of the surgeon always to remove a cancerous growth whenever he has grounds for the belief that the operation can be completely carried out."

THE CHRONIC POLICE-CELL INEBRIATE.

DURING the past month one of the London magistrates has adopted a course which, it may be confidently hoped, will mark a new era in our social treatment of the chronic inebriates of the police-court. We allude to the case of the notorious Jane Cakebread, whose name has been familiar to newspaper readers for many years past. This unfortunate woman had been convicted 280 times, or thereabouts, for the offence of being drunk and disorderly, when she was taken in hand by Lady Henry Somerset, who removed her to a charitable home founded for women of her class somewhere in the country. After a stay of some months, during which she failed to manifest the slightest desire for alcohol, the deliberate opinion arrived at by those responsible for her medical care was that she was mentally irresponsible. She soon after left the "home," and promptly went through the old familiar programme, with the result that she was with little delay haled before a justice of the peace. On this occasion, however, the criminal career of Jane Cakebread was suspended indefinitely by the decision of the magistrate that on account of her mental condition she was to be handed over to the safe keeping of the Poor-law authorities. To the general public this decision of the bench may not possess a great deal of significance, but there can nevertheless be little doubt that it marks a new departure of great importance in the administration of

minor justice. The chief wonder appears to be that such a course was not adopted with regard to this unhappy woman long before her 280th appearance in the dock. Her marked eccentricities of language, the ease with which she became intoxicated, the apparent absence of any moral sense, and her repeated convictions, were so many sign posts that have for many a year pointed with unerring finger in the direction of mental aberration. Yet this poor, half-witted Bedlamite has spent a large proportion of her adult life in gaol as a responsible criminal. Like many other chronic inebriates affected with a similar weakness of mind and infirmity of will, she has become "known to the police," and has long since drifted into the ranks of those outcasts whose lives are mainly passed in gaols and in workhouses. Now that at last her irresponsible condition has been recognised from the bench, it is to be hoped that similar cases will in future receive careful investigation, and that these repeated convictions of chronic inebriates will become a thing of the past. It is clearly a matter of extreme difficulty and delicacy to interfere with the liberty of the subject in cases of chronic drunkenness. Few people, however, would raise any objection to regulations if carefully safe guarded from the point of view both of the public generally and of the afflicted individuals in particular. After a certain number of convictions for drunk and disorderly conduct, for instance, it would be safe enough to direct that the mental condition of the offender should be examined by an independent body of medical experts. If found to be irresponsible the next step would obviously be to treat the inebriate as an ordinary lunatic, and put him under appropriate curative or palliative treatment. In this way modern society would be saved from the standing scandal of the repeated and savage punishment of weak-witted chronic inebriates. The general question may be stated in somewhat the following way:—How is a civilised community to deal with the special form of moral insanity which manifests itself in the shape of chronic inebriety? There can be no doubt whatever that the system which punishes this manifestation as a crime is a relic of pre-scientific and barbarous ages. Any punitive step whatever, if undertaken against a morally irresponsible individual, appears to us to be simply indefensible. We should be glad to see every magistrate grounded in the principles of mental pathology. Such a training would, at any rate, to some extent render him alive to the necessities of the case. It is obvious that persons of ill-balanced intellect are of all others the most likely to be put on their trial on criminal charges. Some authorities, indeed, assume the extreme general position that all crime is the outcome of diseased brain action. It is not for a moment to be supposed that the better education of the judges in the workings of normal and abnormal minds would prevent many grave miscarriages of justice in the sentencing of mentally irresponsible persons. At the same time, however, it would serve to some extent to keep their minds open as to the bearings and possibilities of criminal mental pathology. What we have always advocated is an independent

board of medical men skilled in the study of insanity to be available in our law courts from the highest to the lowest in the land.

Notes on Current Topics.

The Army Medical Department and the Ashanti Expedition

It was felt from the beginning, when the Ashanti expedition was decided on, that the medical officers attached to the forces would be called upon to play a prominent part in the operations. The extent, however, to which this assumption was correct is now becoming apparent in the accounts of the work carried out by the expedition which have been appearing in the public press. But among all the references to the duties discharged by the medical officers, we feel that the Army Medical Department generally will appreciate most that which has appeared in our contemporary the *Army and Navy Gazette*. We read as follows in its issue for last week:—"As the Medical Department of the Army has recently been subjected to severe criticism it is only fair to notice that when submitted to a severe ordeal, as undoubtedly was the late Ashanti expedition, the authorities responsible during a very anxious period acquitted themselves most admirably—results proving how perfect the arrangements were, both at home and on the theatre of action, how wise and comprehensive the forethought, how energetic the execution of trying duties. In this connection a correspondent, a combatant officer, writes: 'I am bound to say that I never saw anything to equal the unwavering devotion of all ranks of the medical staff. Day and night have I seen the doctors here labouring to save life. They were simply a band of heroes, and I only wish that some of their detractors and blackballers in Service clubland could have been here to have seen for themselves what England's soldier-doctors can do when put to the test of service. On the principle of honour to whom honour is due, I trust you will allow me to say that Surgeon-Colonel Taylor and his staff are entitled to every credit, and this, I trust, will be accorded them officially, as I can answer for it, it is, unofficially, throughout this force.'" This kindly paragraph of our valued contemporary, and its correspondent's communication, will, we are convinced, have a beneficial effect upon those who are accustomed to traduce the officers of the Army Medical Department.

An English Judge on the Anti-Vaccination Question.

A REMARKABLE state of things is at present disturbing the minds of the people of Gloucester. The town in question, as is commonly known, is one of the few centres in England in which the will of the anti-vaccinationist has been allowed to obtain a sway. In the course of last week Mr. Justice Grantham attended at the town for the purpose of opening the Winter Assizes there, and in his charge to the Grand Jury he

stated that he had received a communication from the authorities in Gloucester to the effect that small-pox was prevalent in the city and had been so for some little time past. Although every step had been taken to prevent any spread of the disease he had been asked to authorise an order to be issued closing all the public galleries in the court, so that no one should be allowed to attend the assizes save those on business. This he deemed was a very serious thing to do, and the question occurred to him if the outbreak was such that, for precautionary reasons, the public should not be permitted in the court, whether he was justified in bringing together into a town, where disease was prevalent, persons from all parts of the country, of all ages and both sexes, and in all states of health. The judge, therefore, held that his proper course was to communicate with the Lord Chancellor, with the result that the assizes were ordered to be removed to Cheltenham. Since, however, this decision had been arrived at the Judge observed that another reason for the removal had come under his notice. He understood that in Gloucester there were many people who, for the sake of a better name, called themselves anti-vaccinationists—that was, they resented the opinion that was generally expressed in the country, and by persons in authority, that all children should be vaccinated. When, therefore, he heard that the local authorities refused to compel persons to have their children vaccinated he thought it was more desirable than ever to take the step which had been taken because there were in the town many people—children and adults—who had not been vaccinated. It may be after this that the “authorities in Gloucester” will take these weighty remarks of Mr. Justice Grantham into serious consideration. It could not have been very satisfactory for them to have heard the Judge’s reasons for the removal of the assizes to Cheltenham.

The Apostle of Degeneration and the English Race.

Most of us, we presume, who have read Max Nordau’s “Degeneration,” arrived at the conclusion that the sweeping remarks of the author as to the advancing degeneracy of mankind were intended to have a general application. But judging by some recent observations respecting the English race, published by Max Nordau in the *Neue Freie Presse*, no such interpretation could have been meant. Apparently, it is the case that too much cannot be said in favour of the race of Englishmen. But Max Nordau shall give his own convictions upon this subject, and they are as follows:—“The British a nation of shopkeepers? Shopkeepers, indeed! Those who fought at Hastings like giants and Titans, who subdued two continents, are ruling two hundred million Asiatics by the will and nerve of a couple of thousand of their race, who brought to their knees such men as Napoleon I and Nicholas I, and who still have their Jamesons to demonstrate that their old strength of will and power of ruling over others have not yet died out! If these are the characteristics of shopkeepers, what is the essential difference between shopkeepers and the heroes of

the Greek myth? The ruling classes of England are the most powerful race of masters the world has seen since the Republic of Rome and the early Roman Empire. To please an Englishman one must be strong and daring. The English are a bluff race, incomparable friends, and terrible enemies, rather proud of being more feared than loved.” These are pleasant things to have had said about us by one who has shown himself to be so shrewd an observer of human nature. But, perhaps, Max Nordau’s convictions in this regard were strengthened by his recent visit to England—after his book on “Degeneration” had been published.

Board School Children and Spectacles.

If the Education Department has done anything, it has certainly played an important part in adding to the number of children wearing spectacles. By some, the increased use of spectacles is attributed to the want of wisdom of the Department in taxing the eyes of children. But to this assumption we cannot agree. The real explanation of the increase in spectacled children lies, we believe, in the fact that the Board School teachers wisely complain to the parents of the children when the latter are found to have faulty vision, as the result of which, advice is sought at the nearest hospital in which the diseases of the eye are attended to. In the majority of cases, the inability to see properly is found to be due to some error of refraction; and after this has been properly estimated, a pair of spectacles is ordered for its correction. Thus it is that the child returns to school with the appliance in question. In former days, no trouble was taken to relieve the child of the ocular discomforts associated with refractive error of which it complained. But the reverse is the case under present circumstances, a fact which needs no further demonstration. *Appropos* of this subject at the annual meeting of the Bradford Eye and Ear Hospital last week it was stated that during the past twelve months two thousand pairs of spectacles were ordered for patients, whereas ten years ago the number required was only three hundred.

The Football Season.

In a recent editorial the *New York Medical Record* amusingly remarks, “The football season is over, and the football player has retired to the classic shades of his Varsity, there to give the lumbar enlargement of his spinal cord its necessary rest, and to cause the fallow grey matter of his cerebral convolutions to indulge in needful and healthful exercise.” In this country, it may be observed the football season is just at its zenith, the contests becoming keener every day as the matches for the League Championships are being played off. It is satisfactory to note that so far during the current season fewer accidents have been recorded, and less injury to life and limb has occurred, than has been the case for some years. Presumably, however, it cannot be argued from this that the contests have been less vigorously fought, or that any diminution has taken place in the enthusiasm with which the results have been striven for. On the contrary, the evidence upon this matter would seem altogether to point in the

other direction. It is now commonly admitted that the fierce rivalry induced among the clubs throughout the country owing to the introduction of the League matches has led so largely to the development of what is known as "professionalism" that football is fast losing its characteristics as a national game. For this the Association game is greatly responsible. In the good old days, when every football match was played under Rugby rules, the pastime could be followed for its own sake, and the professional element was not required. But the progress of the game under the Association rules has worked during recent years a wondrous change for the worse in this respect. However, the evil is now admitted, and some steps will soon be taken to remedy it. The most notable incident in this connection which has just occurred is the announcement that the authorities of Eton College have decided to adopt the Rugby game, and to banish the Association game from the school. This step, it is believed, will be generally followed by the other public schools, and, thus, with this movement beginning and spreading throughout the country, it may be that the Rugby game will ultimately regain all its lost popularity.

The Physical Examination of Competitive Candidates for the Army Medical Service.

SEVERAL of our non-medical contemporaries have recently reverted to a subject to which we have, more than once, called attention as requiring reform. They point out that in connection with the competitive examinations for the Army and other public services, the examination of the candidate as to his health and physical fitness, cannot take place until he has passed his educational test, and that it is thus possible, and not uncommon, for candidates to expend years of labour and much money in qualifying themselves for appointments, from which, after they have been proved to be educationally fit, they are excluded because they suffer from some physical defect. We have never heard any tenable cause why this injustice should continue. In fact, the only reason which has been suggested is that it would be too much trouble for the medical board which is entrusted with the physical examination to have to test the unsuccessful as well as the successful competitors. An argument of this sort is scarcely admissible under any circumstances, but, if the previous physical examination imposed upon the Medical Board any unreasonable labour, we apprehend that the candidates would be well content to pay a special fee for such special examination. We do not suggest that the physical examination after the passing of the educational examination should be dispensed with, for it is obviously necessary that the fitness of the candidate at the last moment of his entry into the service should be guaranteed, but there seems to be no good reason why an additional previous test should not be taken at an earlier stage if the candidate wishes, and that he should thus be afforded the opportunity of deciding whether any absolute and incurable disability, such, for instance, as a high degree of myopia, exists. The private opinion of an unofficial practitioner must always be, in such case, imperfect

and unsatisfying, and we do not see why the reasonable wishes of the competing public should not be met by an alteration of the system which could be so readily effected.

Dublin Hospital Sunday.

THE annual meetings of the supporters of the Fund and that of its Council were held last week and passed with a quietude almost somnolent. The income of the Fund for the past year fell short of that of the previous year by about £200, but this was sufficiently accounted for by the terrible weather which marked the occasion of the annual collection. The deficit would have been £100 more but for a donation of that sum from an individual benefactor. The total amount for distribution was £4,264. The amounts granted varied from £560 to the Meath Hospital, and £536 to the Adelaide, down to £95 given to Mercer's. It is just to the Committee of Council to say that the expenses of administration compare very favourably with those current in other hospital funds, being only 6.18 per cent. of the income. The system of distribution is, however, and has always been at variance with the interest of the sick poor, being framed upon the extraordinary principle that the bulk of the Fund should be given to the hospitals which do least work for the sick poor and have least need for money, while those which are most useful to the community are starved. However, if it is not worth the while of the hospitals which suffer this injustice to raise an agitation against the existing system of distribution, it is certainly not for us to force the consideration of the matter upon them. At present the representation of hospitals on the Fund Council is a perfect farce. Deadheads, whose very existence it is difficult to discover, are appointed from year to year, and when appointed they rarely attend the meetings of the Council, and still more rarely understand anything about the subject, nor can they, as a rule, tell why this or that hospital is mulcted of income which is enjoyed by other more favoured institutions.

Dental Surgeons for the Army.

A DENTIST writing to a Liverpool contemporary suggests that dental officers should be appointed to the Medical Staff of the Army. He states that whenever Army recruits have faulty teeth requiring attention they are despatched to a dental hospital in order to have their teeth put in order before the men can be passed for the Service. Arguing from these facts, he claims that were dentists to be attached to the Medical Staff of the Army it would be better for the men. Perhaps in rare instances this would be the case, but we cannot admit that the dental troubles of Thomas Atkins would be sufficiently grave or numerous as to require a special department for their special treatment. Probably when Thomas Atkins has a tooth which gives him exceptional trouble he is always quite willing to part with it, and the extraction procedure is one which most medical officers in the Army would be able successfully to accomplish. But when the question of stopping teeth, and the more refined processes of the

dental art are concerned, it is true that only a dentist would be able to satisfy Thomas Atkins' demands. In the meantime, however, it will have to be proved whether such demands exist, and, if they exist, whether the country would be justified in providing for them out of the public purse.

Asbestos for Boots and Shoes.

ALL who enjoy walking exercise and desire warm dry feet will be glad to hear that a company has been formed to utilise asbestos in the manufacture of boots. Asbestos possesses the essential properties for a comfortable boot; it is light, and is a non-conductor; with the mineral replacing leather or felt, as an inner sole, the boot may be worn on the hot flags of a city street on a summer day, or on slush of snow in winter, without the wearer being made uncomfortable by either. During the Eighteenth Century asbestos was much more used for wearing apparel than at present, even two centuries earlier the spinning of asbestos was a recognised industry in Venice. Signor Castaquatta carried the art to such perfection that his woven asbestos was soft and tractable, resembling dressed lambkin. He could thicken or thin the product at pleasure, and thus either make it a very white skin or a very white paper. Signor Ciampini describes the method of weaving asbestos thus:—The stone is laid to soak in warm water, then opened and divided by the hands, that the earthy matter may be washed out. The washing being several times repeated, the flax-like filaments are collected and dried; and they are most conveniently spun with an addition of flax. Two or three filaments of the asbestos are easily twisted along with the flaxen thread, if the operator's fingers are kept oiled. The cloth also when woven is best preserved by oil from breaking or wasting. On exposure to the fire the flax and oil burn out, and the cloth remains pure and white, a light, durable, non-conducting fabric. It will thus be seen that woven asbestos is admirably suited for the inner soles of boots

An Interesting Discovery in Comparative Pathology.

THE prevalence of sheep fluke in the Australian sheep farms has often proved a very serious matter to the stock owners, and for a long time efforts have been made to discover the "intermediate host" through which the animals became infected. This discovery has now been accomplished. Dr. Cobb, of Sydney, working on behalf of the Agricultural Department of the colony, has just clearly shown that the "intermediate host" is the common land snail (*Bulinus brazieri*). The importance of this fact is such that it will lead to the enforcement of several recommendations having for their object the suppression of the fluke. Observation has shown that the greatest enemy the snail has is the peewee. Dr. Cobb is of the opinion that the peewee is the best friend that the sheep owner has in the Australian colonies. Other birds, such as the blue crane, wild duck, and the domestic duck, also feed on the snail.

Hydrogen Sulphide in the Urine.

THE rare instances in which hydrogen sulphide is met with in the urine renders each case that occurs worthy of being recorded. A correspondent to a contemporary gives the notes of the following case which recently occurred in his practice. A negress, aged seventeen, a primipara, developed eclampsia, both ante-partal and post-partal. The labour was normal otherwise, and the child was born alive. The urine contained 10 per cent. by weight of albumen. On the fifth day after the delivery, hydrogen sulphide was detected in the urine. The absorption of this poisonous gas into her blood caused the development of toxic symptoms such as restlessness, vomiting, delirium, delusions, and intermittent pulse, and complaints of smelling bad odours. The bladder was washed out with a weak solution of permanganate of potassium, and the symptoms soon subsided.

The Direct Representation for Ireland.

THE poll for this position of honour will have been almost completed when this journal reaches our readers. It closes on the evening of the 27th, and when our readers in Ireland receive this issue, there will be just time for those who have not yet sent in their voting papers to be in time for the count which commences on Friday morning, by sending them forward in all haste. Until the votes are counted, a process which will be completed on Saturday evening, there can be nothing more trustworthy than speculation to decide the issue. The competitors, Drs. Jacob, Cuming, and Thomson, are generally considered to be very closely matched. If a Dublin man is asked, he predicts the return of Dr. Thomson; if an Ulster man, the return of Dr. Cuming; and, if a provincial, the triumph of Dr. Jacob.

Mr. R. B. Anderson and the Queen.

WE learn that Mr. R. B. Anderson has decided, since the Court of Appeal has refused to listen to any further application from him, to petition Her Majesty the Queen in respect to his case. The petition sets forth the many grievous wrongs and oppressions wilfully and illegally done to him and suffered by him at the hands of the judges, Her Majesty's servants and representatives, in the infringement of his rights and liberties as a British subject. Mr. Anderson deserves the sympathy and assistance of the public generally in the plucky fight which he is making for the redress of his wrongs. All of those who have taken the trouble to read the published reports of his case must admit that a more extraordinary revelation of judicial persecution could scarcely have been brought under their notice. Indeed, no one can help feeling that there is more of that which belongs to fiction than reality in the injustice which has been meted out to him.

THE son of a solicitor in Dudley, Worcestershire, died last week under chloroform, which had been administered for the purpose of the extraction of some teeth. The anaesthetic was given in the house of a local dentist by a medical practitioner.

The M.D., U.S.A. Question.

IN the leading article in our issue of last week with reference to the prosecution of "Dr." Bridgwater in the Cardiff Police-court, we commented upon the apparent absence of any reference to the recent important decision by Mr. Shiel (confirmed on appeal in the Ferdinand case). We are, however, informed by Mr. Hempson, solicitor to the Medical Defence Union, that, not only was the case of Ferdinand quoted for the prosecution, but other cases also in which the Union had been successful in obtaining convictions for similar offences. We learn, moreover, from the same authority that the stipendiary magistrate at Cardiff has been asked to state a case by way of appeal for the opinion of the High Court. It is to be trusted that the magistrate will raise no difficulty towards enabling a higher tribunal to consider his decision.

A Phenomenal Prospective Legacy for a Medical Man.

INDIAN potentates have commonly taken some practical step to show their appreciation of the value of the services of their European medical attendants. Several cases are, indeed, on record where large sums in the form of fees have thus been paid to the latter. But the most phenomenal instance of the kind which has come under our notice is that which is reported in the *Deccan Budget*. The Nawab Fakr-ul-mulk has, we are told, made a will leaving £600,000, or 2,000,000 rupees, to his medical man. This immense sum will come to the latter on the death of his patient.

The Question of Private Lunatic Asylums.

THE question of private lunatic asylums came before the House of Commons last week in relation to the case of the young lady who some months ago was confined in an asylum, for holding certain ultra views in regard to the marriage laws. The Home Secretary intimated that the Lord Chancellor had a Bill in preparation which, among other things, will aim at improving and extending the precautions against any abuse of the lunacy laws. It is, doubtless, generally known that the last Lunacy Act precluded the establishment of any private asylum in the future.

The New Photography.

AT the Medical Society, London, on the 24th instant, Mr. Sydney Rowland gave a demonstration of the new photography. Starting from a single electric spark, the lecturer demonstrated the effect of gradually reducing the pressure of the gas through which the spark passed, until gradually, when the air was almost completely exhausted, the character of the discharge completely changed. From this point the practical application of the discharge in vacuo might be said to begin. Some very beautiful Geissler and Crooke's tubes were shown, one in particular, showing the mechanical energy developed from the cathode rays by the revolution of a mica vane illustrating very well the theory already established by Professor J. J. Thomson, of Cambridge, that the X rays were generated at the point of impact of these

rays with the glass. The relative advantages of Tesla and Rumkorff's coils in illuminating the vacuum tubes were discussed, with the conclusion that the Tesla currents were in every way preferable if only the tubes could be got to stand the strain. A new method of sensitising the plates was mentioned. Using this method, the lecturer had succeeded in producing a negative of the bones of the hand in twenty seconds. Some of its applications to surgery and medicine were then entered into.

The "Medical Press and Circular" and the "Times."

IN our issue last week we drew attention to the feeling which has been caused in this country and America in consequence of a certain decision of the authorities responsible for the arrangements of the International Medical Congress at Moscow next year. The paragraph in which our remarks appeared was largely quoted by our lay contemporaries, by whom the source was duly acknowledged. There was, however, one exception, and that was the *Times*. We have simply to state that we cannot congratulate the *Times* upon the courtesy which it displayed upon this occasion, nor can we understand why the editor should have appropriated a paragraph emanating from this journal, while his contemporaries had, without exception, courteously acknowledged its source.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.—The meeting of this Society on Wednesday last was entirely given over to the exhibition of patients and specimens. Dr. James showed patients suffering from Pseudo-Hypertrophic Paralysis and Hydronephrosis. Mr. Cotterill showed a remarkable case of Vascular Tumour of the Face which had lasted for twenty years and had been treated without avail in many ways. The tumour involved the right side of the face, and was of large size. Electrolysis had done no good, but he thought that he would try the effect of tying the internal carotid on the affected side. Among the specimens shown were: A Skull and Brain illustrating old-standing depressed fractures without symptoms, Elephantiasis of the Labium Majus, weighing several pounds, from Mombasa, by Mr. Cathcart; Sections of a Glio-sarcoma of the Pons involving all the Cranial Nerve Origins on one side save those of the first three, by Dr. Bramwell; Albumoes from a Urine in a case of Chronic Nephritis, by Dr. Gillespie; and specimens from a case of Hæmorrhagic Pancreatitis, by Dr. Leith.

THE TYPHOID OUTBREAK AT DUNBAR.—Since calling attention to the anomalous state of the Public Health Service of Haddingtonshire in our last number, we find that the District Committee have a notice of motion before them to the following effect:—That this Committee memorialise the County Council to take into serious consideration the present unsatisfactory arrangements as to the county and district medical officers, and in doing so, suggest the propriety of terminating these arrangements, and in lieu thereof appoint a county medical officer, free from private practice, resident in the county, to devote his whole time to the duties of his office, with permission to the district committees of the county to appoint him also district medical officer. A copy of this to be sent to the Local Government Board. Such a course is in exact accordance with what we said last week, and we can only hope that the County Council will be large-minded

enough to put an end to the present position of sanitary administration in East Lothian.

MEDICAL EDUCATION OF WOMEN.—The sixth annual report of the Scottish Association for the Medical Education of Women and the Medical College for Women, Chambers Street, Edinburgh, states that the past year has again shown a very marked increase in the attendance at the college of the Association, and also steady work and creditable progress on the part of the students. As the growth of the college demanded increased accommodation, especially in the anatomical department, an arrangement has been made which has given the students excellent practical anatomy rooms and class rooms in a most convenient locality, and has added greatly to their comfort. The Court is strongly of opinion that the only satisfactory way to make the College for Women what it should be, and a fit companion to the other educational establishments in Edinburgh, is to have a building belonging more or less to the Association.

LEITH HOSPITAL.—The authorities of this hospital have been engaged for some time back in setting their house in order. The staff has been almost entirely changed within the last year, and a new batch of appointments was made last week. It will be noticed that most of the new officers hail from Edinburgh. The following are the appointments:—H. C. Langwill, M.R.C.P.E. (from the dispensary department), to be one of the physicians; Alexander Miles, M.D., F.R.C.S.E., to be one of the surgeons; David Berry Hart, F.R.C.P.E., to be physician for diseases peculiar to women; Dr. W. G. Sim, F.R.C.S.E., to be ophthalmic surgeon; Dr. Theodore Shennan to be pathologist, and Dr. George Elder, Dr. J. S. Fowler, and Dr. A. Scot-Skirving to be medical officers in the dispensary department.

MEDICAL SOCIETY OF LONDON.

The meeting on Monday evening last (February 24th) opened with a very interesting paper by Mr. Hurry Fenwick on the assistance to be derived from the painful manifestations associated with the presence of stone in the kidney in respect of its exact situation. He pointed out that, whereas with the stone in the pelvis there are frequent attacks of colic, with radiation of the pain and bladder irritability, these symptoms were usually absent when the stone is embedded in the cortex. When the stone is situated in the parenchyma of the kidney, i.e., in the pyramids, the patient is usually unable to sleep except on the side of the affected organ, lying on the other side giving rise to pain. With pelvic stones the patient could lie on the affected side.

Dr. Rolfe (by proxy) followed with a paper on the cases of renal pain calling for medical, as distinguished from surgical, treatment. He divided the cases into those in which the pain was dependent on reflex nervous disturbance, and the so-called "aching" kidney. The former is met with in association with valvular disease of the heart, more particularly aortic, and thoracic, and especially abdominal, aneurism. The aching kidney, he suggested, was usually due to movable kidney, but was also met with as the result of tight-lacing, and from undue acidity of the urine or other excess of some normal constituent of the urine.

Mr. Sydney Rowland gave a demonstration of the new photography, to which reference is made on page 222.

EXAMINATION PAPERS FOR THE DIPLOMA IN PUBLIC HEALTH AT THE UNIVERSITIES OF OXFORD, CAMBRIDGE DURHAM, (a) AND VICTORIA, AND THE JOINT BOARD OF ENGLAND.

(Continued from page 202)

DURHAM, APRIL 15TH, 1895.—No. I.

[1. Give an outline of the Sanitary Provisions of the Public Health Acts Amendment Act, 1890.

2. Fill in the diseases and other causes of death in Great Britain in the following Nosological Table;—

(a) Examination for the Degree of Bachelor in Hygiene, and for the Diploma in Public Health (U.F.H.) Durham

- I.—*Specific, Febrile, or Zymotic Diseases*, viz.:—
 - (1) Miasmatic, (2) Diarrhoeal, (3) Venereal, (4) Septic.
- II.—*Parasitic Diseases.*
- III.—*Dietic Diseases.*
- IV.—*Constitutional Diseases.*
- V.—*Developmental Diseases.*
- VI.—*Local Diseases in the following systems*, viz.:—
 - (1) Nervous, (2) Circulatory, (3) Respiratory, (4) Digestive, (5) Urinary, (6) Reproductive.

Indicate other causes of death not provided for in the above table.

3. Name the diseases with which Small-pox and Typhus respectively may be confused, indicating the signs leading to error, and those by which a correct diagnosis is to be made in each case.

4. Describe the origin and mode of Spread of Wool-sorters' Disease, and the measures to be taken for its prevention.]

[5. What is the meaning of the term "Specific Infectious Diseases"? How are these diseases characterised?

6. Enumerate the diseases with which Enteric Fever may be confounded, and give the differential diagnosis of the conditions mentioned.]

Directions:—The answers are to be made up into two sets, indicated by the brackets on the questions. Each set is to bear the Candidate's number.

THURSDAY, APRIL 18TH, 1895.

No. IV.—*Practical Hygiene, Climatology, Meteorology, &c., and Vital Statistics.*

[1. Show the different liabilities at various age-periods to sickness and death from the several Zymotic and Respiratory Diseases, also from Diseases of the Circulatory and Nervous systems.

2. Describe two systems of Ventilation and Warming applicable for Board Schools and other public institutions.

3. Describe the "Old Dutch" Process of White Lead Making, showing the dangers to the health of the workers, the protective regulations in force, and any other measures you would adopt for preventing lead poisoning in this manufacture.

4. Name the different sources and causes of Plumbism other than the Manufacture of White Lead, as affecting (a) workpeople, and (b) other persons.]

[5. Discuss the question of the aerial convection of Small-pox from Hospitals.

6. Give the Registrar-General's classification of communicable diseases.]

Directions:—The answers are to be made up into two sets, indicated by the brackets on the questions. Each set is to bear the Candidate's number.

VICTORIA UNIVERSITY, JULY 17TH, 1895.—PART II.

Medicine.

(Four questions only to be answered.)

1. Enumerate the diseases which may arise from meat of bad quality. Describe briefly in each case the chief features by which you can recognise that the flesh is diseased.

2. How does soil influence the causation of disease? Discuss this factor more especially in regard to the Etiology and prevalence of (a) acute rheumatism, (b) diarrhoea.

3. What diseases are more particularly associated with coal and copper mining, button-making, and the manufacture of artificial flowers? Explain upon what causes the prevalence of any special disease in these particular callings depends, and indicate the precautions necessary to minimise or obviate their action.

4. What are the lesions most usually observed after phosphorus poisoning? Give an account of the circumstances under which this mode of poisoning may occur in practice.

5. Give an account of the etiology of Tuberculosis. What are the modes of tubercular infection that are of practical importance?

WEDNESDAY, JULY 17TH, 1895.—PART II.

Sanitary Administration, &c.

1. Under what circumstances is a Medical Officer of Health justified in describing a dwelling as "unfit for human habitation," and how may a closing order be obtained?
2. Give the substance of the several legal enactments intended to provide against the sale of unsound or unwholesome foods.
3. Define a bye-law, and explain the difference between a bye-law and a regulation. What is meant by the terms Power of Entry; Service of Notice; Contributory Place; Provisional Order; Court of Summary Jurisdiction?
4. What statutory measures can be taken for the disinfection of infected articles and premises? Distinguish between those which are applicable under the general sanitary law and those under adoptive legislation.
5. Compare the system of Quarantine as employed abroad with that adopted in England for the prevention of cholera, and give instances of the operation of these two systems in recent epidemics of the disease.

CONJOINT BOARD OF ENGLAND, MONDAY, JULY 8TH, 1895.

No. 1.

1. Give an account of the Ray-fungus disease of animals, describing both naked-eye and microscopic appearances. State also what you know of the etiology of the disease, and give your views as to its communicability from animals to man.
2. To what extent do you consider Climate and conditions of the soil to be factors in the Causation of Acute Rheumatism?
3. In what ways does the health of children deteriorate from insufficiency of air and light?
Show in what respects the regulations relating to the erection of dwellings in large cities fail to protect the public health in this direction.
4. Give a short description of the trade-processes in which Sulphur compounds are produced or employed, and the way in which the health of the workers in such trade processes may be injuriously affected.
What practical suggestions would you make for the general improvement of the health conditions of the workers?
5. Enumerate and describe the rashes that may resemble the eruption of Scarlatina, giving the differential diagnosis in each case.

MONDAY, JULY 8TH, 1895.—No. II.

1. In an urban district (population 28,000) it is proposed to utilise, for the purposes of an isolation hospital, an old-fashioned detached house capable of accommodating 15 beds. The house has a fair-sized garden attached. What are the chief practical objections to the proposal?
2. *Burial grounds predispose to disease and are the source of actual disease.* Review critically the evidence on which the above statement is based.
Give the substance of the Memorandum of the Local Government Board "On the Sanitary requirements of Cemeteries."
3. Describe the form of *Table of Deaths classified according to Diseases, Ages, and Localities, K³(A)*, which is required by the Local Government Board to accompany the Annual Report of every Medical Officer of Health under its regulations. State clearly the rules to be observed in order that this Table may furnish the basis of a true record of mortality for the district to which it relates.
4. What are the provisions of Parts II. and III. of the Housing of the Working Classes Act, as they affect the condition of Rural Sanitary Districts? What have hitherto been the chief sources of hindrance in their practical operation?
5. What are the Powers and Duties of Sanitary Authorities and their Officers in respect of the pollution of Rivers by Trade Refuse?

MR. GEORGE RICHMOND has contributed £1,000 to endow a surgical bed in St. Thomas's Hospital in memory of the late James Richmond.

WE regret to learn that Dr. H. Rigby Matheson was drowned at Strahan by the capsizing of a yacht.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

THE EDINBURGH M.D.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I cannot help feeling some degree of amusement at the simplicity of your correspondent "Salisbury Craigs." Is he really of opinion that the amount of logic which it was necessary to know to pass the preliminary examination of the Edinburgh University could have had the very slightest effect on the brains of the candidates? The mere knowledge of the outward signs and symbols of the science of logic, a knowledge of "Barbara" and her sisters, which was chiefly parrot-like, could never increase the logical faculty in the students' mind. Logic in Edinburgh has always been something of a farce, and with so much else to learn the student is better without it. Your correspondent takes a very low view of medical teaching. As far as I am able to judge, proper teaching of the necessary subjects in the medical curriculum is, throughout, a very valuable lesson in logic, inductive and deductive. To use a common phrase a medical man is, as a rule, as able to put two and two together, perhaps I should say more able, than the average logician of Oxford or Cambridge, who are more concerned with the form than the substance. He must be the veriest dullard who does not pick up from his courses on chemistry, physiology, or medicine itself, a logical instinct. Why, every chemical equation is a syllogism, every physiological experiment or medical diagnosis must exhibit a process of logical reasoning. Unless your correspondent would go the length of advising that each aspirant for the degree of M.D. should take a degree in Arts before commencing his medical studies, so that he should receive something worth the learning, I am afraid that his suggestion would be of little avail.

In your number of last week you published a communication from your Scottish correspondent which refers to the manner in which the clinical part of the new examination for the M.D. degree is to be carried out. It seems to me that the proposal to make the examination simply a reflex of the M.B., C.M. examination is very weak. You justly say that a specialist may be well worthy of the higher honours without having to display an extensive knowledge of everything that appertains to general medicine. I admit that a narrow-minded specialist is not a satisfactory ornament to the profession, but it must be remembered that he has already had to go through the lower examinations in common with the future general practitioners. Specialism, owing to the great increase of scientific knowledge and acquirements, has expanded much of late, and, however much we may deplore the fact, must expand still more in the future. Would it be fair to ask a professed pathologist of some years standing, or a physiologist, who intends devoting his life to the teaching of his subject, to undergo a clinical examination?

The University of Edinburgh may have smoothed the path for its alumni at the beginning of their work; it would be a pity if it determined to place obstacles in their way at the end.

I am, Sir, yours, &c.,
M.D. EDIN.

Edinburgh, February 22nd, 1896.

MEDICAL TITLES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Quite recently I directed attention in your columns to the extraordinary anomalies of the law on this question, and the subject is again revived by your "leader" in last week's impression. According to the judgment in the case of Ferdinand, a man cannot append the title "M.D." with the qualifying letters "U.S.A." to his name, without the risk of being mulcted in a substantial fine. According to the judgment at Cardiff, in the case of Bridgwater, M.D., U.S.A., he can, as there is no implication that the man who so styles himself is "a registered practitioner of the United Kingdom." Now, I should like to ask pundits in the quibbles of the law whether an "M.D., U.S.A." can legally prefix the title "Dr." to his name, and practise medicine. It is not the practice of

medicine which is illegal, it is the assumption of a medical title. If he cannot do so, has he not as much right to prefix the title "Dr." as the possessors of the worthless and non-registrable title of M.D., or LL.D. from some sham University of Germany or America? There are scores of men in this city, and doubtless in other cities also, who practise medicine and chemistry, who prefix the title "Dr." to their name and who are not in possession of the registrable degree of "M.D." from any University whatsoever. What better right have they to do so than the "M.D., U.S.A."? I recently communicated with Dr. Bateman, of the Medical Defence Union, on this question, and in his reply he states: "With regard to the title 'Dr.' used by persons duly qualified but not holding the M.D. degree, we have no intention of prosecuting. It must be remembered that the M.D. means 'Doctor of Medicine,' whereas the word 'Dr.' simply means any person practising medicine, and is used commonly by the public generally as meaning a practitioner whatever his qualifications may be." This contention I hold to be eminently unsatisfactory and fallacious. It is not the title which the public give that any gentleman assumes. It is his academic distinction, or legal qualification, that a man ought in honour to use in his professional or other capacity; and I humbly submit that if what the public call a man who practises medicine or surgery is the title which he ought to assume then the "M.D., U.S.A.," or the "Ph.D." or the "LL.D.," of the diploma shops has just as valid a right to the title of "Dr." as the man who assumes it while possessing no registrable degree of "M.D." Many medical practitioners possessing only the licence of the Glasgow Faculty—a single qualification simply to practise surgery—style themselves "Dr. ———, Surgeon." This I hold to be fraudulent representation, as these men certainly intend to convey to the public that they are in possession of the "M.D." degree, in addition to a surgical qualification, and I need hardly add that it is in the intention to deceive that the law is violated. The Medical Defence Union would be better employed, in my opinion, in endeavouring to settle this important professional question, than in those minor points with which they are often connected throughout the kingdom.

I am, Sir, yours, &c.,
D. CAMPBELL BLACK.

Glasgow, 19th Feb., 1896.

ST. JOHN'S HOSPITAL FOR SKIN DISEASES.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Under the heading "Opening of a New Hospital" *The Times* newspaper publishes a glowing description of the ceremony of inauguration of a new branch of St. John's Hospital for Diseases of the Skin (Leicester Square, London, W.) The new branch is installed in an isolated mansion in the Uxbridge Road, Suburban London, and converted at great cost to its new purpose. We are told that a distinguished company was present, including the Countess of Chesterfield (who "opened" the hospital), her son the Earl, the Bishop of Marlborough, Cardinal Vaughan, and Lieut.-Col. Mercier. The Earl of Chesterfield delivered an address, tracing the development of the institution, and ending with the statement that an annual addition of £2,000 a year would be needed to their income. The Countess, in declaring the hospital open expressed her great pleasure in being associated with her son "in so great and noble a work."

Cardinal Vaughan made a speech, in which he remarked that the aristocracy and gentry of this country knew well the times in which they lived and the duties incumbent upon them. They were to be found taking their part in the public life of the land, in political and civil life, in science and literature, in the defences of the country; but he ventured to think they could be engaged in no work which would commend them more generally or more heartily to the English people than in works of mercy such as that hospital represented.

Now, Sir, I venture to say that everyone of your readers who has adequate knowledge of the question of medical charity, of hospital accommodation, and of the gigantic abuses associated at present with the administration of medical relief will read this report with regret and

with indignation. Every member of the profession knows that there is no real reason for the existence of any hospital for diseases of the skin. Diseases of the skin are received and treated at every general hospital in both the out and in-patient departments. The great hospitals are all languishing for lack of funds, and most of them have many empty beds if not many empty wards. Everyone knows how deplorable is the waste of money inevitable in the administration of the best managed special hospitals; the salaries of the secretaries, the commissions to collectors, the cost of public advertisements appealing for funds, so that the expense of maintaining each bed in these institutions usually exceeds by two or three times the cost of that found necessary in well-managed general hospitals. There exist in London alone some forty or fifty useless or unnecessary special hospitals, whose total income would, if distributed among necessary and deserving institutions, probably suffice to provide all their pressing needs.

Among special hospitals there are many which must be styled not only unnecessary, but shams and frauds—establishments kept up for the personal purposes of their promoters, and the staff who work them.

The unnecessary special hospital abuse is one of the greatest affecting the true welfare of charity, and as every one who has examined the subject is aware, is attended with many other evils. It forms a prime factor in pauperising the people in the matter of medical relief, and inflicts harm in many ways upon the whole medical profession.

Except what I have gathered from an occasional paragraph in newspapers, I know nothing about St. John's Hospital, its promoters, or its staff, and I have not the least doubt they are all animated by the best motives, and acting in perfect good faith.

Nor can we find fault with members of the aristocracy and wealthy members of society, full of fine feelings (and perhaps not overburdened with brains) who lend a ready ear to any plausible plea on behalf of charity; but one looks for something better on the part of dignitaries of the English and Roman Churches like the Bishop of Marlborough and Cardinal Vaughan. It is, indeed, astonishing to find Cardinal Vaughan taking part in promotion of this enterprise and discussing it in the terms he employed.

Judging from his published utterances the Cardinal is distinguished by the strongest common sense; and he has shown himself a deep and earnest student of social problems. It is evident he has not made himself properly familiar with these problems, in so far as they are involved with questions of medical succour of the suffering poor, and in giving his countenance and eloquent support to the undertaking which I criticise he has done more to damage the cause he doubtless has at heart than can be retrieved by any effort he may put forth for many a long day.

I am, Sir, yours, &c.,
HOSPITAL REFORMER.

"THE POOR MOTHERS OF ENGLAND."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The pathetic cry on their behalf by a number of ladies, wives of Members of Parliament, and others, in the London newspapers some months ago, seems to be lost sight of just now in the discussion on Midwives' Registration. This "cry" was considered useful at that period, and served well for the insertion of the thin edge of the wedge, namely, asking for registration for the benefit and the protection of these poor mothers. But now "the cry" has been dropped, and if midwives are registered, they will be empowered to attend any of the mothers of England, rich or poor, for they will be recognised by law, and the confidence of the public will be increased as to their capabilities, and simply because of this legal stamp.

If the above "cry" was to obtain for these poor people more reliable and skilled attendance in their hour of need, why stop at registering women "midwives" only? What about the large army of men who have taken out their full medical curriculum, and have not been able to fully qualify and register according to law as medical practitioners? Why are they not considered? Because they have not had the Obstetrical Society of London to "nego-

tiats" for them with the General Medical Council, as Dr. Champneys has told us was done for these women, in his presidential address delivered a fortnight ago.

In reply to registering men, they will say:—"No, that would be a retrograde step. Would be opening a door for unqualified practice." We retort, "Is not registering uneducated women to practise midwifery a much greater retrograde step than it would be to register as 'midwives' those men who are all but qualified as medical men? If registration is for the benefit of 'the poor mothers of England,' would this latter plan not give them more skilled aid than women can offer them? I shall be glad if 'Registrationist' will answer these questions.

I fear these poor unqualified men of England have not gone the right way about it. If they could have "negotiated" with Dr. Champneys and the Obstetrical Society of London and obtained their "diploma," then they would have had powerful diplomatists at their back, who would have interceded for them with the General Medical Council, and they would now have been in possession of a document recognised by that august body! And yet, on the other hand, the executive committee of the General Medical Council resolved on Monday, February 24th, 1895, that "the Council cannot approve of any document professing to qualify persons for any practice in medicine, surgery, or midwifery, issued by any body or institution which is not a medical authority under the Medical Acts"! Surely, this looks very like a "solution of continuity," when they approved of the certificate, that Dr. Champneys refers to, of the Obstetrical Society, in May last!

I wonder what they who have been punished at various times by the Council by being struck off the Register will think of those who had been "warned" "negotiating" with their judges? Does this not look as if there is one law for the high and another for the lowly, who have no influential "negotiators"?

I am, Sir, yours, &c.,
G. H. BROADBENT.

8 Ardwick Green, Manchester,
Feb. 22nd, 1896.

Literature.

HAAB'S ATLAS OF OPHTHALMOSCOPY. (a)

So far as ophthalmological literature is concerned, this volume, which the enterprise of the publishers has placed within the reach of English readers, marks an epoch worthy of special notice. Within the compass of an ordinary-sized text-book "Haab's Atlas of Ophthalmoscopy" contains a complete series of admirable coloured drawings of the normal and pathological appearances of the fundus. The full significance of this fact stands out in bold relief, when it is remembered that hitherto all atlases of the kind have been large, bulky tomes, suitable only for works of reference in the public medical libraries. Such works, monumental as they may be of the industry, skill, and originality of their authors, have nevertheless, it may well be understood, fulfilled but a limited usefulness to both students and practitioners alike. They were almost inaccessible, and their size and price for the most part have banished them from the libraries of ophthalmic surgeons. We have, therefore, no hesitation in saying that the volume before us is a most valuable addition to the literature of this special subject, and will find favour where previous ventures in this department have failed. The drawings are excellent in every way, accurate as to detail, artistic as to colour, and beautifully reproduced. Each drawing is furnished with letter-press description, concisely pointing out the various details depicted. In all the drawings number no less than sixty-four. The first fifty pages or so of the volume are taken up with some practical remarks on the ophthalmoscope, retinoscopy, errors of refraction, &c. These in part, owing to their conciseness, will be found specially useful by students and practitioners who have neither the time nor the opportunity to consult larger works on the subject. It only remains for us to add that

(a) "An Atlas of Ophthalmoscopy: with an Introduction to the Use of the Ophthalmoscope." By Dr. O. Haab, Professor of Ophthalmology, University of Zurich. With 64 coloured plates. Translated and Edited by Ernest Clarke, M.D., B.S. (Lond.), F.R.C.S. London: Baillière, Tinsley and Cox. 1895. Price 10s. 6d.

the translator and editor, Dr. Ernest Clarke, has done his work well, and that the book, for the reasons above mentioned, is worthy of the highest commendation.

THE YEAR-BOOK OF TREATMENT FOR 1896. (a)

FROM the preface we learn that this is the twelfth issue of this popular year-book, and a line of familiar red-backed books on the shelf tells that for more than a decade we have not unfrequently consulted Cassell's Year-Book. The great majority of the issues are much alike, the editor wisely adhering to an arrangement which the medical profession approved of, but progress and time works some changes, and we are glad to find a section on Tropical Diseases in this issue.

Where all the sections are well edited it may look invidious to select some for special notice; we, however, think that Dr. Reynold's section on the treatment of nervous and mental diseases; Dr. Hale White's section on diseases of the stomach, intestines and liver; Dr. Dawson Williams' on the medical diseases of children; and Mr. William Rose's section on general surgery are of such excellence that we draw our readers' attention specially to them.

The section on anæsthetics has the great value of emphasising everything which appeared in the medical journals during the first year which was unfavourable to chloroform, and displaying much ingenuity in minimising the evils of etherisation. Bronchitis follows etherisation in the practice of Muret "was this due," he inquires, "to etherisation or to exposure, &c." page 173. On page 172 we read Nauwerck's theory that pneumonia following etherisation is caused by the pathogenic bacteria which exist so abundantly in the buccal cavity. Yet we get no hint to explain why etherisation sends them down to the lung and chloroformisation does not.

Obituary.

DR. JAMES FITZGERALD, OF NEWTOWNBUTLER

We regret to record the death last week of this estimable gentleman, one of the veterans of the profession in Ireland. He was stricken with hemiplegia at the ripe age of 88, and survived only five days. He held the Membership of the London College of Surgeons, obtained as far back as the year 1833, having been previously a pupil of Sir Astley Cooper. He retired from the Poor-law Service on pension a great many years ago, and occupied himself in the duties of a country gentleman and an active member of the Church of Ireland. He was greatly esteemed in his neighbourhood, and was laid to his rest by one of his oldest friends, the Bishop of Clogher.

Medical News.

St. Thomas's Hospital, London.

THE following gentlemen have been selected as House Officers from Tuesday, March 3rd, 1896:—Resident House Physicians: F. B. Thornton, L.R.C.P., M.R.C.S. (extension); W. E. Dixon, B.Sc.Lond., L.R.C.P., M.R.C.S. (extension). Non-Resident House Physicians: E. W. Palin, M.A., M.B., B.Ch.Oxon., L.R.C.P., M.R.C.S.; P. S. Hichens, M.A., M.B., B.Ch.Oxon., L.R.C.P., M.R.C.S. House Surgeons: L. A. R. Wallace, B.A., M.B., B.Ch.Oxon., L.R.C.P., M.R.C.S.; H. C. Crouch, L.R.C.P., M.R.C.S.; J. L. Prain, L.R.C.P., M.R.C.S.; G. J. Conford, B.A., M.B., B.Ch.Oxon., L.R.C.P., M.R.C.S. Assistant House Surgeons: B. Dyball, L.R.C.P., M.R.C.S.; P. W. Kent, L.R.C.P., M.R.C.S.; J. Smith, B.A., M.B., B.C. Cantab., L.R.C.P., M.R.C.S.; W. D. Frazier, L.R.C.P., M.R.C.S. Obstetric House Physicians: Senior—G. G. Genge, L.R.C.P., M.R.C.S. Junior—C. W. Grant Wilson, L.R.C.P., M.R.C.S. Ophthalmic House Surgeons: Senior—A. H. P. Dawnay, L.R.C.P., M.R.C.S. Junior—E. A. Saunders, M.A., M.B., B.Ch.Oxon., L.R.C.P., M.R.C.S. Clinical Assistants in the Special Departments for Diseases

(a) "The Year-Book of Treatment for 1896." A Critical Review for Practitioners of Medicine and Surgery. London: Cassell and Co., Limited.

of the Throat: W. Thornely, B.A.Cantab., L.R.C.P., M.R.C.S. (extension); P. L. Blaber, L.R.C.P., M.R.C.S.; Skin: W. D. Knocker, L.R.C.P., M.B.C.S. (extension); G. R. Harcourt, L.R.C.P., M.R.C.S. (extension); Ear: W. H. J. Paterson, L.R.C.P., M.R.C.S.; R. G. Strange, L.R.C.P., M.B.C.S. Clinical Assistants in the Electrical Department: F. J. Brakenridge, L.R.C.P., M.R.C.S. (extension); P. J. A. Seccombe, M.A.Cantab., L.R.C.P., M.R.C.S.

British Medical Association—Visit to Carlisle.

SOME progress has been made with the arrangements for the meeting of the British Medical Association at Carlisle on July 28th, 29th, 30th, and 31st. The President-elect, Dr. Henry Barnes, of Carlisle, will deliver the presidential address; the address in medicine will be given by Sir Dyce Duckworth, M.D., LL.D., and Dr. Maclaren, of Carlisle, will deliver the address in surgery. The sectional programme has to some extent been arranged. There will be nine sections. The presidents and vice-presidents of the different sections have been appointed. The names of the presidents are as follows:—Medicine, Dr. George F. Duffey, physician to the City of Dublin Hospital, and Lecturer on Clinical Medicine; surgery, Dr. Alexander Ogston, Professor of Surgery in Aberdeen University; midwifery, Dr. J. Halliday Croom, Obstetric Physician, Royal Infirmary, Edinburgh; public medicine, Sir Joseph Ewart, M.D., Brighton; psychology, Dr. J. A. Campbell, Medical Superintendent, Cumberland and Westmoreland Asylum at Carlisle; pathology, and bacteriology, Dr. Sheridan Delépine, Professor of Pathology, Owens College, Manchester; ophthalmology, Dr. David Little, Lecturer on Ophthalmology, Owens College, Manchester; diseases of children, Dr. James Finlayson, Physician to the Western Infirmary, Glasgow; ethics, Dr. T. F. P'Anson, Whitehaven. The Bishop of Carlisle and the civic authorities have signified their intention to do all in their power to make the gathering a successful one.

The Notorious Hernia Specialist—Sherman.

At the Manchester Assizes last week, George Greenwood, lodging house keeper, of Rochdale, sued Samuel John Sherman, described as a "specialist" in the treatment of hernia and rupture, for the return of money said to have been obtained by fraud. The defendant neither put in an appearance himself nor was represented by counsel. Mr. Langdon said the charge against the defendant, who carried on his business in Chancery Lane, London, and King Street, Manchester, was that by means of lies he had obtained from the plaintiff the sum of eighty guineas. For some twelve or fifteen years, the plaintiff had been suffering from a double rupture, but by wearing an ordinary truss he was able to go about and work without any trouble. The son of the plaintiff in June last saw an advertisement in a Manchester evening paper stating that rupture was cured without operation by defendant, and that all who wished to get rid of rupture and truss should send to him. The plaintiff resolved to see Sherman and went to the offices in King Street, Manchester. Before he was admitted he had to pay a fee of a guinea. Sherman examined the plaintiff, in reply to whom he said he could cure the rupture, and, in fact, make the plaintiff stronger than he had ever been before. But it was a difficult case, and he said he should want 100 guineas for the cure. Photographs were shown to the plaintiff of men who had been cured or were in process of being cured. The plaintiff ultimately agreed to pay 80 guineas for the treatment and cure. The money was paid on the following day, and Sherman then fitted on to the plaintiff a bad truss and gave him a bottle of lotion. The truss not being a proper appliance, the plaintiff had suffered a good deal of pain from it. In the beginning of this year he saw Mr. Whitehead, of the Manchester Royal Infirmary, who told him that the truss and the lotion were of no use, and were in fact rather bad than good. The plaintiff having given evidence, Mr. Whitehead was called and stated that rupture in an adult was not curable without an operation. The truss given by the defendant to the plaintiff was an improper truss. The "compound" would soften the skin rather than harden it, and so it would do rather more harm than good. The jury gave a verdict for the plaintiff for 85 guineas.

PASS LISTS.

Army Medical Service.

THE following is an official list of candidates for commissions in the Medical Staff of Her Majesty's Army who were successful at the recent Competitive Examination in London, placed in the order of merit:—

Names.	Marks.	Names.	Marks.
Birrell, K. T. F.	2740	MacDougall, A. J.	2207
Morris, A. H.	2308	Riddick, G. B.	2185
Archer, S. A.	2297	Hewetson, H.	2167
Cochrane, E. W. W.	2224	Clements, R. W.	2100
Swably, M.	2210		

Indian Medical Service.

THE following is an official list of the candidates for Her Majesty's Indian Medical Service who were successful at the Competitive Examination held in London on February 7th, 1896, and following days, arranged in order of merit:—

Names.	Marks.	Names.	Marks.
Walton, H. J.	3186	Brown, H. R.	2351
Ainsworth, H.	3010	Fleming, A. N.	2316
Cornwall, J. W.	2983	James, S. P.	2304
Smith, F. A.	2846	Pluch, A. E. H.	2283
Stevenson, J. S.	2810	Dee, F.	2255
Dickson, H. A. D.	2804	Mell, F. O. N.	2268
Richards, W. G.	2518	Brown, F. D.	2259
Dick, M.	2513	Hammond, F. A. L.	2223
Miller, A.	2476		

University of London.

THE following are official lists of candidates who passed the recent Intermediate Examinations in Medicine:—

Entire Examination.—Second Division.

Alexander, K. B., Guy's Hosp.	Forster, L. C. E., Sch. of Med. for Women
Anderson, W. M., London Hosp.	Glover, J. A., Guy's Hospital
Balderston, R., Guy's Hosp.	Kelly, C. F. M., Owens Coll.
Barron, H. T., Westminster Hosp.	Knight, C. V., St. Bart's Hosp.
Belfrage, S. H., University Coll.	Lander, C. L., B. Sc., London Hosp.
Briscoe, J. C., King's College	Law, S. F. C., St. Mary's Hosp.
Cambridge, F. J., St. Bart's Hosp.	Meakin, E. B. M., Sch. of Med. for Women
Clifford, H., University Coll.	Norman, R., London Hosp.
Collens, E. H., Mason College	Perdraun, J. A., University Coll.
Esau, H. L., Guy's Hospital	Uley, C. J., Owens College
Fairbank, H. A. T., Charing Cross Hospital	Watson, J. V., Owens College

Excluding Physiology.

Gates, Edward Alfred, St. Thomas's Hospital. (First Division.)

Second Division.

Raylow, H. C., Westminster Hosp.	Liddell, W. H. S., St. Mary's Hosp.
Bingham, S. O., St. Thomas's Hosp.	Longley, J. A. N., Mason Coll.
Cheesman, H. H., Westminster Hosp.	Owley, G. C., Guy's Hosp.
Everington, H. D., St. Bart's Hosp.	Parrest, E. K. H. A., Guy's Hosp.
F. x. H. K. C., Guy's Hosp.	Parsons, A. C., St. Thomas's Hosp.
Rox. T. H., Yorkshire Coll.	Rhodes, J. H., St. Bart's Hosp.
Gibbins, H. M., St. Bart's Hosp.	Richards, G. M. O., Owens Coll.
Hanson, H. B., Sch. of Med. for Women	Robinson, J. F., St. Bart's Hosp.
Hatfield, R., St. Bart's Hosp.	Rowland, P. W., St. Bart's Hosp.
Iboston, W. C. B., Guy's Hosp.	Tantoo, J. G. C., Mason Coll.
	Taylor, G. P., St. Bart's Hosp.
	Taylor, J., Yorkshire Coll.
	Miller, G. V., University Coll.

Physiology only.—First Division.

Aveline, H. T. S., Bristol Med. School.	Waltie, J. G., London Hosp.
---	-----------------------------

Second Division.

Reid, F. V. O., St. Bart's Hosp.	Scott, W. H., St. Thomas's Hosp.
Crisp, G. B., St. Mary's Hosp.	Stock, W. S. V., Univ. Coll., Bristol.
Günther, H. A., University Coll.	Stuart, W. L., Guy's Hosp.
Hanson, L. K. C., Guy's Hosp.	Thwaites, G. B., St. Thomas's Hosp.
Jones, J. L., University Coll.	Woodbridge, E. W., St. Bart's Hosp.
Northcote, P., St. Thomas's Hosp.	
Rowe, W. T., St. Bart's Hosp.	

Royal College of Surgeons in Ireland.—Fellowship Examination.

THE following gentlemen have passed the primary part of the examination:—

Mervyn Winfred Falkner and Percy Hope Falkner.

The following gentlemen having passed the necessary examination have been admitted Fellows of the College:—

Bernard Robert Chatterton, M.D., B.Ch., Univ. Dub.; Edward Henry Taylor, M.B., B.Ch., Univ. Dub.; Patrick Joseph Fagan, L.R.C.P.I. and L.R.C.S.I., and Alfred Ernest William Ramsbottom, L.R.C.S.I., L.R.C.P.I.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

THE KISBY FUND.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I shall be glad if you will acknowledge the receipt of the following additional subscriptions to above fund.

I am, Sir yours, &c,
F. MCKENNA, M.B., H.M. Sec.

Carriockmacross,

BATHYBES.—A letter addressed to the Registrar, Royal College of Physicians, Pall Mall East, London, will enable our correspondent to obtain the information he desires.

DR. T. MILBANK (Exeter). We regret that we have no space at present to devote to the subject to which our correspondent refers.

THE letters of M. L. and Twice Rejected, are unavoidably crowded out at Press.

MR. SWAN'S second lecture on "Tubercular Disease of the Hip-joint," has been received.

MR. SYDNEY STEPHENSON'S paper on "Epiacleritis Periodica Fugax" is marked for early insertion.

EXIT JANE CAKEBREAD.

AS corollary to the leader in another column, we much regret to learn that Dr. Gordon, medical superintendent of the Hackney Infirmary, is at present incapacitated from duty, suffering from two broken ribs caused by a kick from the notorious Jane Cakebread. It was his duty to see the woman before her removal to the Lunatic Asylum, she having been certified to be insane, and when Cakebread heard her fate she kicked him savagely in the chest. Upon examination it was found that Dr. Gordon was suffering from two broken ribs, and the guardians have appointed another medical officer to undertake the duties during his illness.

DR. CARTER (Liverpool) is thanked for his note.

DR. CRAIGS.—The case is not by any means singular; a "swab" of the throat after six weeks and even double that length of time frequently reveals the presence of bacilli, and illustrates the fact of the long continued contagiousness of diphtheria after the child is supposed to have recovered. We shall be glad to receive full particulars when the case is completed.

Meetings of the Societies

THURSDAY, FEB. 27TH.

ROYAL INSTITUTION.—8 p.m. Prof. H. Marshall Ward: On some Aspects of Modern Botany.

SOCIETY OF ARTS (Imperial Institute, South Kensington).—4.30 p.m. Mr. C. Tripp: The Tobacco Industry of India and the Far East.

FRIDAY, FEB. 28TH.

CLINICAL SOCIETY OF LONDON.—8.30 p.m. Clinical Cases.
ROYAL INSTITUTION.—9 p.m. Mr. J. Murray: Marine Organisms and their Conditions of Environment.

SATURDAY, FEB. 29TH.

ROYAL INSTITUTION.—3 p.m. Lord Rayleigh: Light.

FRIDAY, MARCH 6TH.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—8.15 p.m. At Royal Kent Dispensary, Greenwich. Clinical Evening. Cases, specimens, &c., by the President (Mr. Ernest Clarke), Drs. Collic, Henry, Jocelyne, and others.

Vacancies.

Anderson's College Medical School, Glasgow.—Chair of Midwifery. Information regarding the duties and terms of appointment of John Kidston, Secretary, 50 West Regent Street, Glasgow.

Birkenhead Union.—Resident Assistant Medical Officer of Workhouse and Schools. Salary £60 for the Workhouse and £20 for the schools, with rations, attendance, washing and residence. Applications to John Carter, Clerk to the Guardians, 45 Hamilton square, Birkenhead.

Bolton Infirmary.—Senior and Junior House Surgeons. Salary for the Senior, £120, and for the Junior, £80 per annum, with apartments, board, and attendance. Applications to Peter Kevan, Esq., Hon. Sec., 15 Acrefield, Bolton.

Folkestone, Victoria Hospital.—House Surgeon. Salary £80, rising £10 annually, with board, residence, and washing. Applications, with testimonials, to the Secretary by March 20th.

Manchester Southern and Maternity Hospital.—Resident House Surgeon. Honorarium, £60 per annum with board. Applications to Geo. Wm. Fox, 53 Princess Street, Hon. Sec.

Metropolitan Hospital, Kingsland.—House Physician, House Surgeon, Assistant House Physician, and Assistant House Surgeon. Salary of House Physician and House Surgeon £40 a year. That of the Assistant House Physician and Assistant House Surgeon £0 a year. Applications to be sent by March 7th to Charles H. Byers, M.D., Northumberland County Lunatic Asylum, Morpeth. Assistant Medical Officer. Salary £120 per annum, increasing £10 yearly to £150, with furnished apartments, board and lodging. Applications to Dr. McDowall, at the Asylum.

Ripon Dispensary and Cottage Hospital.—Resident House Surgeon and Dispenser. Salary £70 per annum with board and lodging. Application to F. D. Wise, Hon. Sec.

Warrington Infirmary.—Junior Resident House Surgeon. Salary £100 per annum with furnished residence and board. Application to J. L. Tunstall, Hon. Sec.

Yorkshire College, Leeds.—Demonstrator of Physiology. Salary £150. Particulars of the College Secretary.

Appointments

HARRIS, T., M.D. Lond., F.R.C.S., M.R.C.S., Visiting Physician to the Manchester Royal Lunatic Asylum.

HODGSON, C. E., L.R.C.P., L.R.C.S. (Irel.), Resident Clinical Assistant to the City Asylum, Birmingham.

JONES, ROWLAND H. H., L.R.C.P. Lond., M.R.C.S., D.P.H., Medical Officer for the Workhouse of the Baugor and Beaumaris Union.

LANCASTER, E. LW. CROFT, M.B., B.Ch. Oxon, Physician to the Swansea and South Wales Institution for the Blind.

MILES, W. ERNEST, F.R.C.S. (Eng.), House Surgeon to St. Mark's Hospital for Diseases of the Rectum.

NEWMAN, WILLIAM, M.D., M.R.C.P. Lond., F.R.C.S., Consulting Surgeon to the Stamford and Rutland General Infirmary.

PENNY, W. E., M.R.C.S., L.R.C.P., House Surgeon to Westminster Hospital.

PHILLIPS, GEORGE, M.R.C.S. (Eng.), L.R.C.P. Lond., Junior House Surgeon to the Bury Dispensary Hospital, Lancs.

RICHARDS, A. F. E., M.B., B.C. Camb., L.R.C.P. Lond., M.R.C.S., Medical Officer for the Hospital, Swansea.

SMITH, A. T., M.B., C.M. Aberd., Medical Officer for the Third Sanitary District of the Bromley Union.

STERLL, G., M.D. Edin., C.M., F.R.C.P. Lond., Visiting Physician to the Manchester Royal Lunatic Asylum.

STEVENSON, A. K. M.D., C.M. Irel., Medical Officer for the Drogheda Dispensary District.

TAYLOR, JAS. L.R.C.P. Lond., F.R.C.S., L.F.P.S. Glasg., Consulting Surgeon to the Wrexham Infirmary.

VAWDEY, GEO., L.R.C.P. Lond., L.M. Edin., M.R.C.S., Medical Officer for the Farnborough District Council.

WARD, T. H., M.B., C.M. Edin., Medical Officer for the Second Sanitary District of the Tonnes Union.

WATTS, J. M.A., M.B., B.Ch. Oxon, M.R.C.S. (Eng.), L.R.C.P. Lond., Surgeon to Crofton General Hospital.

WILLIAMS, ED. CRILL, B.A., M.B., B.Ch. Cantab., Physician to Out-patients to the Bristol Hospital for Children and Women.

Births.

ARNOLD.—Feb. 14th, at Oxford Road, Manchester, the wife of Francis Sorell Arnold, M.B. Oxon, of a daughter.

BELL.—Feb. 19th, at Grandisburg, Woodbridge, Suffolk, the wife of Frank Oliphant Bell, M.B., C.M., of a daughter.

CLARKE.—Feb. 16th, at Gladstones Road, West Kensington, W., the wife of William Frederick Clarke, M.D., B.S. Lond., of a son.

COOPER.—Feb. 12th, at Courtfield Road, the wife of G. White Cooper, M.B., of a daughter.

FOTHERGILL.—Feb. 15th, at Olive House, Rochester, Staffs, the wife of George A. Fothergill, M.B., of a son.

GEORGE.—Feb. 23rd, at 1 Burton Road, Brossedbury, the wife of Alfred W. George, M.B., M.R.C.S., of a daughter.

HARRIS.—Feb. 14th, at Holy Innocent's Road, Hornsey, the wife of E. Bernard Harris, M.R.C.S. (Eng.), L.R.C.P. Lond., L.S.A., of a daughter.

PECK.—Feb. 18th, at 64 Gower Street, the wife of Awdry Peck, M.A., Oxon, M.R.C.S., L.R.C.P., of a daughter.

RAWLINSON.—Feb. 16th, at Stuart House, Bognor, the wife of F. Juland Rawlinson, F.R.C.S., of a son.

Marriages.

CROUCH-SMITH.—Feb. 15th, at St. Thomas's Portman Square, London, Charles Percival Crouch, F.R.C.S. (Eng.), M.B. Lond., of Weston-super-Mare, to Annie Farbray, second daughter of Thomas Smith, F.R.C.S. (Eng.), of Stratford Place, W.

TAYLOR-STRAITON.—Feb. 21st, at Sebore, Central India, Harold B. Taylor, State Bally Branch, P.W.D., to Margery, daughter of the late Brigade-Surgeon J. B. Stratton, M.D., Indian Medical Service (By Telegraph.)

Deaths.

FITZGERALD.—Feb. 19th, at Newtownoutler, James Fitzgerald, M.R.C.S. (E. aged 68.

MALCOLM SMITH.—Feb. 20th, at Anwell Place, Hurstpierpoint, Sussex, Geo. J. Malcolm-Smith, M.D., aged 46.

MILES.—Feb. 22nd, at Kandy, Ceylon, Jane Ancoott, wife of Geo. Miles, M.R.C.S., formerly of Plympton, Devon.

ROBERTSON.—Feb. 21st, at 15 Great King Street, Edinburgh, J. Hutchins Robertson, M.D., J.P., late of Singapore, aged 66.

THE PERMANENT CURE OF ANTE-FLEXION BY OPERATION. (a)

By GEORGE E. KEITH, M.B., C.M

WITHOUT entering into the question of dysmenorrhœa in all its phases, I would draw attention to the variety known as obstructive dysmenorrhœa. It seems strange to me, and probably also to others that there can be a doubt whether there is such a thing as obstructive dysmenorrhœa or not. Opinions on this question are, however, divided.

Those who believe in the obstructive theory consider that the pain is frequently due to an alteration in the shape of the uterus or in other words to an ante-flexion of that organ. This flexion occurs either at the junction of the body and cervix or in the cervix itself, and may vary very much in degree. The fundus of the uterus appears always to be directed more towards the pubes than is natural, and the os looks more or less forwards; in a very well marked case the position of the os will show that, if the cervical canal were prolonged forwards, it would be parallel to the cavity of the body of the uterus.

For example, when an examination is made in an extreme case, the finger strikes against the os, which is looking forwards and upwards; the shape of the cervix is not what is usual, the distance between the os and the vaginal junction in front being much shorter than that from the os to the vaginal junction behind. Pushing the finger up in front the body is felt through the anterior fornix. It is thus evident, and it is shown on bi-manual examination, that the uterine canal cannot possibly be in a straight, or even an approximately straight, line.

It is unnecessary to trouble you with the symptoms which may be caused by an ante-flexion, but it is necessary to remember that those tend to become more severe owing to alterations in the lining membrane of the body of the uterus and in the pelvic circulation generally. This must be borne in mind, because the full benefit of the operation to be described does not always appear immediately. The old operation of splitting the cervix has been perfected by Dr. Dudley, of Chicago. His modification does not seem to have met with the attention it deserves, and it is one of great importance, because it does away with the healing by granulation and its accompanying evils. I believe that the object to be aimed at is not the removal of any real or supposititious lessening of the lumen of the uterine canal, but in the rendering of this canal straight, or, at least, in doing away with any marked bend, and in this way relieving the pelvic circulation.

The old operation of dividing the cervix either laterally or through the posterior lip has this great fault, that, unless artificial means be taken to keep the canal dilated, the cut surfaces adhere almost immediately and the malformation is exactly as before. If the canal is rendered permanently enlarged by artificial

means, a slight deformity may be cured, but a marked one will not be relieved, as a rule, because the uterine canal has not been made straight or at least sufficiently straight to allow of the easy exit of the menstrual

FIG. I.

fluid. In addition, more or less cicatricial tissue will be formed. The aim of the operation ought to be to make the canal of the body of the uterus and the cervix into a straight line in such a way that there can be no return of the deformity.

(a) Paper read before the British Gynaecological Society, Feb. 13th!

The following are the steps of the operation:—It is essential to use Sim's speculum, and as this operation may have to be performed on unmarried women the smaller end of the smallest sized speculum, three-quarters of an inch in width, must be the one selected in such cases. It is thus unnecessary to rupture the hymen unless it be very large. The vagina is to be washed out, a tenaculum is to be fixed into the centre of the anterior lip of the cervix and the uterus is drawn slightly downwards to straighten the bend as far as possible. A sound is passed to determine the exact direction of the canal which is then thoroughly dilated, preferably with a Goodell's dilator. This is followed by curetting, a large quantity of fungosities being usually removed. The operator then takes the tenaculum in the left hand and with knee-bent scissors in the right

surfaces, the upper or right, and the lower or left, and each requires to be sutured separately. It will be seen that if the cut surface on one side is doubled on itself so that the point touches the base, and the same is done on the other side, the point, *i.e.*, the os, must be either drawn backwards or the base must be drawn forwards. What happens is that the point is drawn backwards. It is next fixed in this position by sutures. The stitches are put in in the following way, the needle is passed through the whole thickness of the point on one side and from the vaginal surface to the cervical, and in the reverse direction through the whole thickness of the base. (see diagram). The stitch is then tied, thus keeping the cut surface doubled on itself. A similar stitch is then put into the lower side, one stitch on each side being usually sufficient. In this way the incision which was originally longitudinal has become transverse, although in two halves. It will be now noticed that the anterior lip has become elongated, and on bi-manual examination the body of the uterus and the newly-formed os will be found in a straight or almost straight line.

The after-treatment consists in simply keeping the patient in bed for ten days.

CASE I.—For *Dysmenorrhœa and Sterility*. The patient, *æt.* 29, married for eight years, had never menstruated without pain. This pain commenced a few hours before the flow and lasted usually for 24 hours, during which time she had always to keep her bed. The general health was not very good, but what was most distressing to the patient was that she was absolutely sterile. Before I saw her she had undergone a large amount of local treatment without benefit. On examination, the cervix was found to be bent at a right angle to the body, which was somewhat anteverted. After the operation already described had been performed, the patient menstruated without pain, soon became pregnant, and was delivered at full time.

CASE II.—Miss C—, *æt.* 32, suffered from dysmenorrhœa and menorrhagia, which had so affected her general health that she had to give up her situation of a governess. The pain lasted for two days, commencing a few hours before the flow, and although it had been always present at these times it was decidedly becoming worse. The menorrhagia was of more recent date and the quantity of blood lost was said to be four times as much as it had previously been. The usual remedies had apparently all been tried, and as it was essential to the patient that time should not be lost an examination was made at once under an anæsthetic. The cervix was found to be long and anteverted, but not to such a great degree as in the previous case. A similar operation was performed in the summer of 1893. There was little improvement experienced at the first two periods, during the third and fourth there was decidedly less pain and hæmorrhage. The fifth was almost natural in almost every respect, and since then there has been no trouble and the patient is now in perfect health.

CASE III.—The patient, *æt.* 27, had been married four years, and had never been pregnant. She had suffered from dysmenorrhœa since the first period, the pain coming with the flow. On several occasions the canal had been dilated. A year after the operation the patient was still sterile, but this may be accounted for by the fact that none of her husband's four married brothers have had any family. The dysmenorrhœa has been entirely relieved. This case was operated on by Mr. Skene Keith.

CASE IV.—Miss B—, *æt.* 27, first menstruated at the age of 11½ years, and always had pain since she could remember, with excessive flow which lasted a full week. When 17, she suffered from gastric ulcer, and since then the periods have been accompanied by intense headache and sickness, coming on two or three days before the flow. There was dysuria and frequency

FIG. II.

cuts through the whole thickness of the posterior lip of the cervix almost to the vaginal mucous membrane. (see diagram). For convenience I propose to call the end of the cervix at the os the point, and the part where it meets the vagina the base. There are now two cut

of micturition and the patient had to make water as often as thirty times in the twenty-four hours. All these symptoms being worse during the flow. Examination showing a very acute bend. Operation on October 20th. During the night following the operation the patient made water only twice. I had a letter from her doctor last week in which he says: "Miss B—, is very much better, there is now no sickness nor pain with the periods, only a slight headache, the flow is normal and lasts three days and the patient does not require to get up during the night to pass water. There have been three periods since you operated."

TUBERCULAR DISEASE OF THE HIP-JOINT.

By R. L. SWAN, F.R.C.S.I.,

Surgeon to Stevens' and the Orthopedic Hospitals, Dublin.

It will be convenient for clinical purposes to consider the features of hip-joint disease, as they present themselves in three stages. 1st. Where they are of recent origin; where there is no real shortening, but suspicion of disease is excited by familiar symptoms which shall be briefly alluded to. 2nd. Where real shortening has occurred with or without suppuration. 3rd. Where a certain amount of consolidation has occurred with more or less shortening or deformity.

There are considerable differences in the early manifestations of morbus coxæ apparently due to the position of the deposit. If it be at or outside the epiphysal line, the symptoms may not be very acute. The parents of the child will notice a limping gait to which they may not attach much importance. The child may complain of fatigue rather than pain. If the disease progresses, pain at the inner side of the knee will be a prominent symptom, and night cries will be present. The appetite and digestion may be deranged, and the child will look badly.

The symptoms will differ when the articulation is involved upon the circumstances of its primary or secondary implication. In the first instance there may be signs of an acute inflammation ensuing on the receipt of an injury, probably a fall on the outer side of the thigh when the limb is semi-flexed. There will be pain, slight flexion, or abduction. The pain will be referred to the joint itself, and is increased by movement, concussion of the femur, or pressure over the trochanter. In such a case it will be necessary to differentiate between simple and tubercular inflammation of the joint. A few days' rest in bed will settle that question, if simple; the symptoms will subside, but if a focus of tubercular disease be established the signs, if not much aggravated, will remain about the same. After a time, a prominent and invariable symptom is muscular wasting. This may be seen by a comparison of the two limbs, taking a similar point on each for measurement. This sign is of great diagnostic value, and taken in conjunction with limitation of motion, both as regards flexion and rotation, will almost fix the diagnosis. The evidence that pain affords in the case of a young child is extremely misleading, as such patients invariably cry from apprehension, and the infliction of pain in an examination is undesirable, and to be avoided. In making an examination, the child should, when the clothes have been removed, be made to stand, facing the surgeon. The affected limb will be usually advanced, and the foot will touch the ground by the anterior part of the sole. The anterior superior spine will be depressed below that of the opposite side, and the limb will appear longer than its fellow, the lengthening, however, being only apparent, as will be found, by measurement. From the posterior view, it will be learned that the glutei are flattened at the affected side; that there is an apparent widening of the natis

owing to the loss of the muscular prominence and an obliteration of the fold below the gluteus maximus. This muscular wasting is observable in all the crural muscles, and is an atrophic process of a rapid nature, superadded to what must be viewed as a minor cause, namely, the wasting due to functional disuse. The child should now be placed on a flat table covered with a blanket, lying on its back. If the limbs are placed parallel to each other and flat on the table, it will be found that the loins are arched forwards. This indicates flexion, and the amount of this deformity is recognised when the back touches the table. If the anterior superior spine is lower than the other, abduction is present. The amount is manifest by moving the limbs outward till both spines are on a level. If, which is not a common occurrence, the affected side be higher than the other, it shows adduction, and its amount may be ascertained by moving the limb inwards till a horizontal line will pass through both these points.

It is necessary in the early stage of hip-joint disease to bear in mind the following conditions, with a view to their rejection:—1. Infantile paralysis. This may be simulated by the muscular wasting, and imperfect circulation of the limb. The limitation of motion at the joint, and the history, will render the diagnosis clear. 2. The lordosis of rachitis, with sub-acute epiphysitis. Here, however, the abundant evidences of a general rachitic diathesis will determine the question. 3. Spinal disease with psoas abscess. Here, although flexion may be present, the rotary movements of the joint are unaffected, and positive evidence of spinal disease may exist. 4. Gluteal or other extra-articular abscess. Here we must be guided by the absolute condition of the joint, by the concomitant symptoms, and by the history. 5. Congenital dislocation of the femur. In such a case, the absence of pain, the peculiar gait, the shortening without marked inversion, and the history will be sufficient guides. 6. Periostitis of upper extremity of femur. Here the symptoms are extremely acute. The pain and tenderness are excessive. There is high temperature, and even convulsions may occur. At a comparatively early period signs of septicæmia may supervene. 7. Sacro-iliac disease. By fixing the pelvis, the movements of the joint, whether flexion-extension or rotation, are unimpaired. The progression is also distinctive of sacro-iliac disease. This, in my experience, appears to be a disease of adults, except in very exceptional instances, while hip-joint disease is essentially a disease of childhood. 8. The term usually named "hysterical joint," and to which Sir James Paget has applied the term "neuro-mimesis." This condition will often tax the diagnostic skill of the surgeon, the more so, as it may undoubtedly co-exist with incipient disease of the joint, and is sometimes associated with general evidence of the hysterical habit. But there is an inconsistency of symptoms. The pain is often referred to the skin, and apparently produced by superficial manipulation, which would have no effect in genuine disease of the joint. As was pointed out by Hilton, the nervous relations to the hip-joint are those which have a direct relation to the supply of the uterine appendages. The condition, however, is not confined to the female, but is found in both sexes. The postural symptoms are unusual and erratic, and there is an exaggeration of all the subjective signs. At the same time, there is an absence of pyrexia, and of the presence of those symptoms which indicate joint mischief. There are no night cries, and the immobility of the joint is not constant. By directing the attention of the patient to some engrossing subjects, manipulations are borne without complaint, which would otherwise elicit cries of pain. There is no muscular wasting, or, at least, only what is due to functional muscular disuse. In a case of this kind the surgeon must not commit himself to a hasty

opinion but, until he has had opportunities sufficient to fully make up his mind on the subject, he must treat the case as if the joint were really implicated.

There are some rare or accidental conditions which may render diagnosis difficult. One is an inflammation of the bursa under the tendon of the psoas and iliacus. Another, which the following case will exemplify:—A. H., set. 10, was seized with intense pain in the right hip. I was called to see him the next morning. There was some pyrexia, and the boy screamed if the limb were touched. I desisted from any examination, and ordered him warm fomentations to the part. The following day a well-marked eruption of herpes zoster, following the course of the ilio-inguinal nerve, was evident, and explained the circumstances.

THE OBJECTS AND LIMITS OF OPERATIONS FOR CANCER. (2)

By W. WATSON CHEYNE, F.R.S.,

Professor of Surgery at King's College; Surgeon to King's College Hospital.

ONE of the departments in which there has been such activity of late years is in the treatment of cancerous diseases. The last few years have seen marked alterations in the older methods of operating in these cases, and also the introduction of operations in regions and of an extent formerly not thought of. Opinions differ very much at the present time as to the utility of many of these surgical procedures, and it is a matter of much interest and importance to consider the results which have been obtained, and to come to some definite conclusions as to their value. And it is with a view of trying to estimate the value of the work done in this department that I have decided to discuss in these lectures the objects which we should aim at, and the limits to which we may go in operating for cancerous diseases.

By cancer I mean the carcinomata, the essential feature of which is continuous and excessive growth of epithelium. Once this growth has commenced, nothing that we know of has any power to stop it. It invades the surrounding tissues, it spreads along the lymphatic vessels, or is carried by these vessels to the nearest lymphatic glands; it passes from one lymphatic gland or one chain of lymphatic glands to another, till it ultimately reaches the main lymphatic trunks, through which it enters the blood stream, and is deposited in distant organs and parts of the body. Deposited in these distant organs it again grows, and the same cycle of events follows, or would follow, were it not that the patient soon succumbs from general poisoning as the result of absorption of materials elaborated at the seat of the disease, from interference with the vital functions owing to the presence of the growth in important organs, from repeated hæmorrhages due to erosion of blood vessels, and so on. Once this overgrowth of epithelium has begun it goes on inexorably, unless we can arrest it, to the one fatal end.

Let us pass on now to the subject proper of these lectures—namely, the *objects and limits of operation* in cases of this disease. The primary object of operation in cancer is, of course, the prolongation of the patient's life and the alleviation of his local trouble, and what I propose to assert in these lectures is that these results are in most cases best attained by aiming, where possible, at the cure of the disease. Up till quite recently, and even now, many surgeons approach operation in these cases impressed with the view that real cure is practically hopeless, and that, with a few rare exceptions, the most that can be expected is prolongation of life for a variable length of time. They therefore oppose elaborate and extensive operations which in themselves must involve considerable risk of life and are content with fairly free removal of noticeable disease; in some cases, indeed, they do not even go so far. For example, in cases of mammary cancer, even where some enlarged glands are to be felt in the axilla, they comfort themselves with the idea that the glands may only be enlarged from irritation and not from cancerous deposit,

and therefore leave them alone until their true cancerous nature is only too evident. Of course, if operations are performed in this manner and with these views, it is no wonder that these surgeons are confirmed in their views and go on operating on cancer with the sole object of prolonging life for a comparatively short time. In discussing the curability of the disease I have already mentioned, evidence as regards cancer of the extremities, lips, and uterus, which shows that a real cure is obtainable in a very considerable proportion of cases, and in the following lectures I shall try to produce similar evidence as regards other parts. I therefore hold, and would strongly urge, the view that the first question to be kept before us in investigating a case of cancer is whether there is any possibility of curing the disease or not. Such a point of view makes a very great difference in the operation, for it is not then sufficient to remove only the noticeable disease, but it is necessary to take away, as far as possible, the parts in which disease may have become disseminated, although still unrecognisable—in other words, possibly infected lymphatic areas. Thus, if the skin is affected, a considerable portion around must be taken away, and this is the more necessary where the infection of the skin has come from beneath, as, for example, where cancers of the breast reach the surface, for the dissemination in the cutaneous lymphatic plexus is often under these circumstances very rapid and extensive, and this is probably due in part to the larger size of the deep cutaneous plexus, which will, in the latter case, be first involved. Again, where muscle is infected, the cancer cells are very rapidly and early driven along the lymphatic vessels of the muscle, and even though there may only be one visible nodule in the muscle, the whole or the greater part of it must be looked on as suspicious, and must be removed if there is to be anything like certainty in attaining the object of the operation—namely, the patient's cure. Again, as regards the lymphatic glands, we know that from a very early period they become affected, and that, of course, without any visible enlargement in the first instance; and, in addition to this infection of the glands without enlargement, plugs of cancer cells very often stick in the lymphatic vessels on their way to the glands. Hence it is necessary in all cases where the disease has lasted any time or extended at all deeply, not only to remove the primary mass freely, but also to take away the whole lymphatic area up to, and including the nearest lymphatic glands. Thus the operation performed with the object of curing the disease becomes a much more extensive one, and consequently much more serious, than that which simply aims at getting rid of the main trouble for a time and prolonging the patient's life.

The primary object of operation in these cases being, therefore, cure, the limits of the radical operation are where there is no reasonable prospect of removing the whole disease, or where, along with a very poor prospect of success, there is a very high mortality from the attempt. In such cases I do not think that operation should be mentioned at all, for even where the patient recovers from it and has presumably two or three months added to his life few would, I think, thank one for it, seeing that these two or three months have been spent in convalescing from a serious and, in the end, useless operation. But even in cases where hopes of cure or marked prolongation of life by a radical operation are out of the question operation may sometimes be advisable, with the object of removing symptoms which are immediately threatening to life, such operations, for example, as tracheotomy, colotomy, &c., or, in the second place, with the object of taking away the primary disease from a part, such as the mouth or throat, where its continued development means intense pain and trouble, and thus of substituting for these troubles an easier death from exhaustion. A *sine quâ non* of such operations must, however, be that they are reasonably free from immediate risk, and with regard to the second class that there is a prospect of attaining the object of the operation—namely, the entire removal of the disease from the part operated on. I do not think that a dangerous operation is allowable for simple relief of symptoms, however proper it may be if a cure may be hoped for.

There are thus two different objects to be held in view, and two different questions as regards operation which we must bear in mind in treating a case of cancer—namely (1) Can we reasonably hope for a cure? for if we can, a

serious or dangerous operation is permissible; or (2) Cure not being possible, can we decidedly ameliorate the patient's condition by operation, such operation, however, not involving any great risk of life?

It is, of course, impossible for me in the time at my disposal to discuss the objects and limits of operation for cancer in all parts of the body, and I have therefore selected three regions for examination—namely, (1) the breast, (2) the throat, and (3) the intestinal tract, as these three regions illustrate very well all the points bearing on our subject.

Before going on to discuss the results of operation for cancer of the breast I must very shortly indicate the sort of procedure which I think is necessary, and as I have already written on this subject I need not go at all fully into details. Knowing the very early period at which the cancer cells get into the lymphatic vessels, an operation to be at all complete must include the primary disease, the lymph channels leading from it, and the whole mass of the nearest lymphatic glands. It does not, however, follow that when these glands are enlarged it is not absolutely necessary to go beyond the first group because, for a time at any rate, the disease seems to be held back at that point; but, as I say, the minimum operation for cancer which will offer anything like a real chance of cure must take away everything up to, and including, the first chain of glands. Hence, in the case of the breast we must remove the primary disease, the whole breast tissue in which the lymphatics run from the breast to the axilla, and the whole of the axillary glands. In this connection we must remember that recent researches have shown that the breast is a very much more extensive organ than was formerly supposed, and that by the old method of operating practically only the central part was taken away. Lobules of the breast run in the fat over the pectoral muscle nearly up to the clavicle, well into the axillary line, almost on to the sternum, and downwards on to the origin of the abdominal muscles. In the deeper part, also, the lobules of the breast are intimately connected with the pectoral fascia, and the removal of the breast without simultaneous thorough removal of the pectoral fascia inevitably means that numerous lobules are left behind. Hence our skin incisions must be very much more free than formerly was the rule, and for my own part I always take away the skin coextensive with the prominent part of the organ. There is another reason for taking away this large amount of skin—namely, the existence of the suspensory ligaments of the breast, in which lymphatic vessels run from the organ to the skin, and these are not at all infrequently infected with cancer cells. In addition to this portion absolutely taken away, the skin all round must be raised, leaving fat and lobules of the breast, as high as the clavicle, as far inwards as the middle of the sternum, downwards on to the abdominal muscles, and outwards on to the latissimus dorsi, and one advantage of this free undermining of the skin is that in the great majority of cases one can subsequently bring the edges together by means of stitches. Where the tumour is situated towards one side of the breast additional portions of skin must be taken away in a V-shaped manner, so that all the skin from the vicinity of the disease is removed. The skin flaps being held up, the pectoral muscle must be exposed at the upper part, and then, in order to ensure the removal of the fascia, a layer of the whole surface of the muscle must be taken away, and when the lower and outer edge of the pectoral muscle is reached the fascia over the serratus magnus and the whole fatty tissue containing lymphatics, as far back as the edge of the latissimus dorsi, must be detached. In this way the primary disease, the breast, and the lymphatic vessels running in the fat and pectoral fascia towards the axilla are separated, and then one proceeds to clear out the whole contents of the axilla, finally leaving the nerves and vessels thoroughly cleansed, as in an anatomical dissection. One first follows the fat and fascia running between the pectoralis major and minor on to the costa-coracoid membrane; and then I explore the axillary vein at the lower part and tear open its sheath along its whole length. Then, raising the pectoralis minor, I begin at the very apex of the axilla right up under the clavicle, and with a curved blunt instrument (the one I find most useful is a periosteum detacher invented by Dr. Greville Macdonald for operations on the

nasal septum), and the finger detach the whole fat and included glands and lymphatic vessels till everything except the important structures in the axilla has been got away. It is very important also that the whole tissue should be removed in one piece; in the first place it is of great advantage in clearing the axilla to have the parts dragged down by the weight of the breast, and in the second place it is very important not to cut through tissue which may be actually diseased, and which may lead to subsequent infection of the wound, as might be the case were the mamma taken away in the first instance and the axillary tissues removed subsequently. And this risk of soiling of the wound is no imaginary one; had I time I could bring forward evidence to show that recurrence may be due to this cause, and that if it can possibly be avoided a malignant tumour should not be cut into, and on no account should it be removed piecemeal, as is sometimes done in other parts of the body.

This operation is, in my opinion, the least extensive which ought to be done, even in a simple case, if the object is to cure the patient, but it must be modified and extended in most instances according to circumstances. Where the skin is much tacked down over the tumour, although it may not be actually involved in the disease, the cutaneous lymphatic vessels and those running in the suspensory ligaments are apt to be affected over a wide area, and hence it is necessary in such cases to cut exceptionally wide of the disease. Where the tumour itself actually involves the skin, however, we know that the disease has almost certainly spread widely in the cutaneous lymphatic plexus, and in such a case one must not hesitate to remove the skin extremely freely and to leave a wound the edges of which it may not be possible to bring together. If such a wound is left it can very readily be closed by skin grafting, either at the time of the original operation, or if the patient is too exhausted about ten days or a fortnight afterwards.

Where the tumour is adherent to the pectoral fascia, as is very commonly the case, I think it is advisable to take away the whole thickness of the muscle at that part, and as the lymph tends to be forced onwards in the direction of the muscular fibres the mass of muscle removed should be detached along its whole length, from its origin to its insertion. In operating on such cases, as I approach the neighbourhood of the tumour I usually sink my hand through the muscle, and then rapidly separate the part grasped from origin to insertion, and detach it at both ends, and, as a matter of fact, in many of my cases I have done this, and have thus removed a considerable part of the lower portion of the pectoral muscle. Halsted and others advise that the pectoral muscle, at any rate its sternal origin, should be taken away in every case, partly in order to get thoroughly rid of the pectoral fascia, and partly in order to be able to clear out the axilla more effectually. As will be evident when I come to compare my statistics with Halsted's, this is really not necessary unless there are actual nodules in the substance of the muscle, more especially where the lower portion of the muscle is removed in the manner I have described there is no difficulty whatever in pulling up the remains of the pectoral muscle sufficiently to obtain complete access to the upper part of the axilla.

Where the muscle itself is actually diseased—that is to say, where there are one or more nodules in the muscular substance—it has been pointed out by Heidenhain that the whole muscle must be looked on as infected, for the muscular contractions very quickly distribute the contents of the lymphatic vessels over it. He therefore advises complete removal of the pectoralis major under these circumstances. I am inclined to think, however, that even in these cases it is often sufficient to take away the sternal origin of the muscle, and that the clavicular portion may be left unless there is actual disease present in it. The connection between the two portions is not very intimate, and from a functional point of view it is of great importance to leave the clavicular part.

Where the glands in the axilla are markedly enlarged the question arises as to how far one should go. In the first place, under such circumstances, it is certainly well to see what one is doing, and while if the pectoral muscle is not affected at all I prefer leaving it, I think it is well to divide it transversely and after the operation to stitch it up. The chief question, however, which has to be con-

sidered is whether, having found the higher axillary glands enlarged, one ought not to go further and remove the glands from the posterior triangle of the neck. Some have, indeed, tried to make it a universal rule that if the axillary glands are at all enlarged those in the posterior triangle must also be taken away; but, as I have already said, the first chain of glands opposes a barrier for a considerable time against the onward spread of the disease, and if only it is thoroughly removed I think one may in most cases be content. Where the cancer is a slow-growing one and only the lower axillary glands are noticeably enlarged I do not, therefore, open up the posterior triangle of the neck, and, so far as I can recall, I have only twice had recurrence in the supra-clavicular glands. If, however, the highest axillary glands are noticeably affected, it stands to reason that the posterior triangle of the neck should be opened. Unfortunately, however, in these cases the line of infection does not so much run into the posterior triangle as along the subclavian vein into the thorax along a route that is only imperfectly accessible even when the posterior triangle is opened, and I have not seen much benefit in the way of finding and rooting out disease as the result of opening up the posterior triangle. Mr. Arbuthnot Lane apparently advocates division of the clavicle and clearing out the supra-clavicular glands in all cases, but this is a method which I cannot at all agree with, and I think that my results bear me out; and where the disease is noticeable in the supra-clavicular glands I believe that cure is hopeless. Some have also advocated amputation at the shoulder-joint with the view of removing the axillary disease still more thoroughly, and this was first done by Sir Joseph Lister, partly at my own instigation. I do not, however, believe that when the disease has gone so far as to necessitate such a procedure there is the slightest probability of curing the patient. The conditions under which amputation of the arm would be necessary are the presence of a large mass in the axilla involving the nerves, for involvement of the vein or the artery, or even of both, does not necessitate amputation. I have on more than one occasion removed portions of the axillary vein to which glands were firmly adherent, and in one case I removed both vein and artery without any loss of vitality or other trouble in the limb; but where the disease is so diffuse as to involve the nerves I think it may be taken as certain that it has extended beyond reach.

As regards the limits of operation for cure in breast cancer, I would exclude from operation:

1. Cases of cancer *en cuirasse*.
2. Cases where there is a large mass in the axilla involving the nerves.
3. Cases where large glands can be felt above the clavicle.
4. All cases where secondary cancers already exist elsewhere.

In none of these instances is there any reasonable prospect of cure; and there will be but little to be gained by subjecting the patient to elaborate operations. Short of these conditions, however, I think a patient ought to have the chance of operation, and though, as I have said before, I would not urge it in bad cases, I think she should be allowed to choose. Even when the operation fails to cure the prolongation of life is often marked, much more so after those thorough operations than after the ordinary imperfect procedure. In this list I have not included cancerous cachexia, as is usually done, because it seems to be due to absorption of products from the cancerous growth, and does not necessarily imply a general internal infection. I have repeatedly seen patients with marked cancerous cachexia improve immensely after the operation.

In considering the results of former and recent methods of operation for cancer of the breast we may look either at the question of cure or at that of local recurrence, and the most satisfactory conclusion is, I think, obtained when we take both together: indeed, since the most recent views have influenced practice the time is too short for the accumulation of any large statistics as regards cure, and one must therefore judge of the effect to some extent by considering the question of recurrence. As regards cure, I have adopted Volkmann's three-year limit, and include under cures all cases which for a period of three years or longer after the

operation have had no local recurrence and have shown no sign of internal cancer. Although this three-year period is, as I have already said, not absolutely accurate—for a certain, though small, proportion of patients who have been alive and well at the end of three years have yet died of cancer—nevertheless it is near enough for all practical purposes, and even if we only secured the patient three years of complete freedom from disease such a gain would fully justify the most radical operation.

As regards the question of local recurrence, it will be seen that a very marked change has been produced by recent methods of operating. Formerly, and even now, local recurrence was extremely frequent (Gross puts it at 68·8 per cent.), and that is not including the cases which have been lost sight of, probably many of which have also recurred). In considering this question of local recurrence, it must also be remembered that up till recently half of these local recurrences took place during the first three months after the operation, and over 80 per cent. during the first year. Halsted has drawn a distinction between what he terms local recurrence and regional recurrence. By local recurrence he means recurrence actually in the track or area of the wound; by regional recurrence he implies recurrence in the neighbourhood, or in glandular areas which were not included in the first operation. Such a distinction is, however, extremely difficult to carry out, and it must often be impossible to determine whether a particular nodule has appeared in the track of the former operation or in its immediate vicinity. As a matter of fact, Halsted's regional recurrences imply an imperfect operation just as much as his local recurrences do; they simply mean that the operation has not been sufficiently extensive, no doubt in many cases because it was impossible; hence I prefer to group both these so-called local and regional recurrences together under the heading of external recurrences, and in my own statistics I speak of two sets of recurrences, namely external recurrences in the wound, its vicinity, or the glands, and internal or metastatic deposits.

The study of my cases fully justifies, I think, what I have said as to the necessity for extensive operation and the advantages to be derived from it. Contrast the older results from Trendelenburg's with 4 per cent. of cures to Fischer's with 15 per cent., or taken altogether an average of about 10 per cent., with the more recent results, varying from 15 per cent. in Küster's practice up to 57 per cent. in my own, and we see that, as the result of greater care in operating, the chances of cure have been largely increased, and the recent results in this table ought to be really better, for a little study of the methods employed by some of the surgeons in the more recent period shows that even there the operations were not so complete as could be wished. The value of even an imperfect improvement is well shown in Esmarch's results, for during the first period up to 1863, the old plan of operating was employed with only 4 per cent. of cures; while afterwards the axilla was cleared out more or less thoroughly, with a jump at once to 18 per cent.—a result more than four times better.

Looking at my own results it will be seen that the effect of thorough removal of the disease is very marked indeed. Taking the cases which have been operated on in the manner described up to three years ago, 21 in number, we have no deaths—12, or 57 per cent. of cures, and 9, or 42·7 per cent., of cases recurring either externally or internally. And if it is objected that 21 is a small number of cases to argue about, I would point out that 12 cures are more than can be shown by many of the older surgeons, although their cases exceed 100. Again, if we study my results from the point of view of the return of the disease, taking in the recent cases, we have a total of 61 cases, with 19 or 31 per cent., of recurrence of metastatic deposits, and among those recurrent cases were two which were really inoperable (in one case, indeed, visible disease being left behind), and which only raise the percentage of failures unnecessarily, and also included in these is one case in which I only assume that there was a metastatic deposit, but have nothing but suspicion to go upon. Excluding the two cases as being inoperable cases, as is usually done in the statistical reports I have quoted, we have 59 cases operated on with reasonable hope of cure, with 16 certain recurrences, or 27 per cent. Some of these, it is true, have only been operated on quite recently, and they therefore are not of much

value, although it must be remembered that by the older methods local occurrences in half the cases took place within three months of the primary operation. At the same time, let us exclude the cases operated on during the last year (and, as I have previously mentioned, over 80 per cent. of the recurrences take place during the first year after operation), I say excluding the cases operated on during the last year we are left with 40 cases, with, at the very worst, 16, or 40 per cent., internal or external recurrences, and that is including Nos. 24 and 29. Taking the external recurrences alone, we have in the 61 cases only 11 external recurrences, or possibly 12, giving an average percentage of external recurrences of 18 per cent. or 19 per cent. As regards the 12 cured cases, of course, recurrence may still take place in some, but taking the most unfavourable statements—viz., König's—that 15 per cent. recur even after three years, we would still be left with 9 cures (and that is leaving out also Case 9 which died without recurrence after three years), or 42 per cent. of definite cures, a result far superior, however it is worked out, to that obtained by the ordinary operation.

I have already referred to Halsted's paper (which up to the present has shown the most favourable results as regards recurrences), and he points out that in his 50 cases he has only had 3 local occurrences; but he has also had 8 regional recurrences, and, as I have already said, I think it is much fairer to combine his local and regional recurrences under one heading, "external recurrences," as I have done in my own statistics, and this gives him a percentage of 22 per cent. external recurrences. Contrast the results as regards external recurrence obtained by Halsted (22 per cent.) and myself (18 per cent.) with those of surgeons operating less completely as worked out by Halsted; for example, Billroth, 85 per cent.; Czerny, 82 per cent.; Fischer, 75 per cent.; Gussenbauer, 64 per cent.; Volkmann, 59 per cent., &c.; and the difference between the old imperfect operation and the thorough one becomes most striking.

While the results, as I have pointed out, are steadily improving, the proportion of cases which succumb to cancer is still considerable, and will not, I think, be much reduced till patients and medical men understand that there is a good chance of radical cure from early and thorough operation in mammary cancer, and that a suspicious lump in the breast, especially in elderly women, is not a thing to be watched, for I may say that over 90 per cent. of the swellings of the breast in elderly women are cancerous.

Contrary to the usual dictum, it is now found that the most favourable of all cases for operation are those of atrophic scirrhus, and the more nearly a cancer approaches the atrophic form the greater is the chance of permanent cure; indeed, I believe that the malignancy of the cancer in the individual cases has a great deal to do with the favourable result of operation, indeed, possibly more than the early period of the operation; but that, expressed in other terms, is only to say that in the less malignant forms of cancer the disease does not diffuse itself as rapidly or widely, and that by an extensive operation we have a better chance of getting beyond it. A patient who comes with a small tumour which has been noticed for several months, which has not markedly increased in size, and in connection with which we have only small glands in the axilla, has a much better chance than one who has found a tumour quite recently which is noticeably enlarging, and in which the axillary glands are of considerable size. In the former case the probability of getting beyond the disease is great on account of its slow spread; in the latter the reverse is the case. Hence while the sooner a cancer of the breast is radically removed the better, one cannot say that the chance of cure is necessarily proportionate to the early period of the operation; in any case, however, the chance of cure of necessity depends on the thoroughness of the operation.

DR. HENRY HICKS of Hendon, whose geological researches are well known, has been elected President of the Geological Society of London. Dr. Hicks is, we believe, the second medical man who has been elevated to this post of honour. The late Mr. Hulke was president of the Society at the time of his death.

Clinical Records.

CASE OF ACCIDENTAL HÆMORRHAGE.

Under the Care of MICHAEL C. O'GORMAN, J.P.,
L.R.C.S.I. and K.Q.R.C.P.I.

SEVERE cases of accidental hæmorrhage have occurred in my practice from time to time, but a case I attended on the 26th January, 1896, seems to me sufficiently interesting for publication. The patient, Mrs. G., æt. 40, a multipara, and in the seventh month of pregnancy, was taken suddenly ill under the following circumstances:—

Her servant left her early on the morning of the 25th January, and consequently she had to do some additional household work, and carried two buckets of water a considerable distance.

She retired to rest at eleven o'clock on that evening feeling quite well, but awoke at twelve in great pain with an intense desire to pass water. She got out of bed for that purpose, when to her surprise she began to bleed copiously. The ordinary chamber soon became full of blood; she fainted, and was lifted into bed.

When I arrived (about 5.30 a.m.) the hæmorrhage had saturated the bed, and the patient was completely collapsed. I immediately administered restoratives, and proceeded to make a vaginal examination. The os was high up, undilated, and frequent gushes of hæmorrhage occurred. Ballottement was easily made out. The patient moaned frequently, and complained of intermittent pains in the vagina, but nothing else.

External auscultation revealed nothing. I could hear no fetal heart or placental bruit, and palpation proved the fetal head was presenting. Under these circumstances, I dismissed all thought of placenta prævia, and proceeded to treat the case as follows. By means of an irrigator, I injected (for about an hour) into the vagina streams of hot and cold water alternately, gave a full dose of ergot, and applied a tight abdominal binder.

The hæmorrhage soon ceased, the patient dozed, and labour pains set in. I made careful vaginal examinations from time to time, but could not discover the cause of the hæmorrhage. Finally, I ruptured the membranes, and the confinement terminated quite normally, with these exceptions.

The fœtus, with umbilical cord twisted round its neck, and placenta were expelled simultaneously. The placenta was small and bloodless. On cutting the cord, it contained no blood, and the fœtus, though well developed (for seven months), was dreadfully anæmic. Quantities of large blood clots were also expelled.

Here was a case in which, I should say, complete separation of the placenta had taken place some time before labour was induced. Its analogy to the symptoms of placenta prævia in the early stage of that abnormal complication is interesting and peculiar.

The patient is making a good recovery, but still weak and anæmic.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, FEBRUARY 29TH, 1896.

The President, Dr. BUZZARD, in the Chair.

CLINICAL EVENING.

A CASE OF IDIOPATHIC MUSCULAR ATROPHY.

DR. CARR showed a lad, æt. 8, the youngest of thirteen children, none of whom had suffered from any similar manifestation, who was a typical case of muscular atrophy or dystrophy of the facio-scapulo-humeral variety. From the hardening of the calf muscles, there is reason to suppose that it may have begun as pseudo-hypertrophic paralysis. The recti-abdominis were singularly atrophied, and he could not raise himself forwards when on his back.

The PRESIDENT observed that the interesting feature of the case lay in the fact of the patient, the youngest of thirteen children, exhibiting alone among them symptoms of a disease which was usually held to be a family disease,

He held the view that many of these so-called family diseases would turn out to be of infective origin. The fact that only this child, out of thirteen, suffered from this affection, did not, at first sight, appear to favour that view, but, on the other hand, it would be extraordinary, if the disease were really hereditary, that only one child should so suffer. The occurrence of these diseases in several members of a family might be explained by exposure to the same influence. The fact that the patient had had measles a year previously, moreover, favoured the idea of an infective origin.

CASE OF ACCIDENTAL VACCINATION.

Dr. ABRAHAM showed a child, *æt.* 3, who presented two ulcers, one on the eyelid and the other on the chin, on a hard base, with the characteristic appearances of accidental vaccination. She was said to have been vaccinated as an infant, but there were no marks on the arms. She had been sleeping with a younger brother who had been successfully vaccinated, and probably that was how she was inoculated.

CONTRACTION OF FOREARM.

Mr. BATTLE showed a boy, *æt.* 12, who last year fell down, and fractured both bones of the forearm. It was put up in splints, but six weeks later, when the splints were removed, there was a large slough of the anterior surface of the forearm, with contraction of the flexors, so that he was at present unable to extend the wrist or the fingers. He has been under treatment at St. Thomas's Hospital for this condition for about five months, but, so far, no improvement has been obtained. The contraction was not influenced by *anæsthesia*.

Mr. W. G. SPENCER pointed out that this was the condition to which Volkmann had given the name of "ischemic paralysis," under which name he suggested this case ought to be described. Such cases were almost hopeless from a treatment point of view, because the contraction was due to inflammatory fibrosis of the muscles. He had seen this condition in a modified degree follow ligature of the femoral artery, tight bandaging, &c.

Mr. ABBUTHNOT LANE took a more favourable view in respect of the prognosis on the strength of two similar cases, in which, by using the tenotomy knife freely, he had succeeded in obtaining very satisfactory results.

Mr. OPENSHAW said he had had two cases like this one and he also had divided the flexors.

Dr. ORMEROD asked whether the author attached any importance to the fact that the terminal phalanges remained unflexed while the others were flexed.

Mr. BATTLE replied in the negative.

CONGENITAL DISLOCATION OF HIP REPLACED BY OPERATION.

Mr. OPENSHAW showed a girl, *æt.* 3, who came to him presenting the typical appearances of congenital dislocation of the hip. He cut down into the joint, removed a portion of the iliac bone at the upper and back part of the acetabulum and got the head back into the cavity. The shortening, which was previously $1\frac{1}{2}$ inches, was thereby reduced to $\frac{1}{2}$ of an inch, and she could walk with a slight limp. The movements of the joint were free in almost every direction, it being four months since the operation. He pointed out that unilateral cases were more favourable for operation than when the dislocation was bilateral. The head could not very well be replaced in the cavity before $2\frac{1}{2}$ years of age on account of the contraction of the acetabulum.

CONGENITAL DISLOCATION OF THE HIP WITH PECULIAR FEATURES.

Dr. TAYLOR showed a woman, *æt.* 23, who came under his care for epilepsy. He noticed that she was lame, and on examining her he found there was (probably) congenital dislocation of the hip. Mr. Ballance concurred in this view. It was peculiar in that there was very great mobility of the joint, this being associated with abnormal mobility in the corresponding knee as well as in the opposite knee. The limb was much shortened with corresponding lateral spinal curvature. There was much grating on moving the femur and it sometimes seemed to slip into a hole as if there were the remains of an acetabulum.

Mr. WALLIS said that after seeing this patient walk and noticing how easily she did so, he was disposed to congratulate her on having escaped operative interference.

Mr. GORDON BRODIE recalled the case of a lad with a similar condition who could walk several miles without inconvenience, and under these circumstances he too was inclined to doubt the desirability of operative interference.

Mr. BATTLE observed that in this case there seemed to be very little neck left and he presumed that, as in cases of injury, there has been some atrophy and absorption of the upper end of the bone.

The PRESIDENT suggested that the condition might possibly be the remains of an attack of infantile paralysis.

Dr. TAYLOR said that idea had occurred to him but he had not been able to elicit any information pointing to any such attack.

Mr. OPENSHAW recalled an interesting case of genu recurvatum, a condition which was attributed to faulty intra-uterine position, and he pointed out that most cases of congenital dislocation of the hip occurred in children born with a breech presentation, observing that this patient presented two of the features attributed to faulty intra-uterine position. Before $2\frac{1}{2}$ years of age, Lorenzo now preferred to apply extension, but between that age and 10 he still advocated this operation. He did not think it was a justifiable operation after 10 years of age.

Mr. TARGETT pointed out that the head of the bone having been outside the cavity would explain an absence of roundness.

Dr. TAYLOR, in reply, said that the child, the eldest, was born after a tedious labour, but the mother did not know whether the presentation was abnormal.

CASE OF ECTOPION VESICÆ.

Mr. H. B. ROBINSON showed a child, *æt.* 4, with ectopion vesicæ in its simplest form. The umbilical cicatrix was very large, prominent, and was situated only a short distance above the pelvis. The upper margin was well defined, and laterally its margins were directed downwards and outwards to the separated pubic crests, in relation with widely-diverging recti muscles. The pelvic symphysis was absent, and the bones were united by a firm fibrous band. The bladder and urethra were intact, but the clitoris was bifid, and the vaginal opening was a vertical slit to the left of the midline. *Per rectum*, the uterus appeared to be normal. On passing a catheter, its point could be felt plainly under the tissue above the pubes. As there was so much protrusion, he cut down, dissected off part of the fascia covering the recti, and brought the flaps together in the middle, thus providing much additional support to the abdominal wall.

DOUBLE FACIAL PARALYSIS.

Dr. H. E. TURNER showed a woman, *æt.* 25, with no history of rheumatism or of anything in particular, who after exposure to a draught three months ago developed facial paralysis on the left side. Six weeks later the condition on the left side remaining permanent, and without conscious exposure, paralysis suddenly supervened on the other side of the face as complete as in the first instance. There was actually complete loss of expressional and volitional movements on both sides, but no affection of taste or hearing.

The PRESIDENT observed that such cases were very rare, though he had seen one following influenza. By rare he meant rare in this form, for it might, of course, occur in disease of the pons.

Dr. ORMEROD recalled the case of a man whom he had seen a few years ago with the double affection equally well marked. He was at the time suffering from syphilis, and he assumed that it was probably due to syphilitic disease of the facial nerves.

Dr. MOTT remembered a similar case in a boy, the paralysis coming on the other side of the face within a day or two of the first attack. He recovered perfectly in about six weeks.

OSTEITIS DEFORMANS.

Dr. H. G. MACKENZIE showed a man, *æt.* 48, who dated his illness from a fall eight years ago. He presented marked bowing of the tibia and femora, with much thickening of the bones. There was marked deformity of the thorax, and the skull was very "bossy," its size being increased upwards as well as antero-posteriorly. Since December of last year he had on three occasions experienced a snap followed by pain and local swelling, but no crepitus, twice over the ribs, and on the last occasion in

the leg. In view of the resemblance of this affection to osteo-malacia he had tried a course of red-bone marrow, but though the treatment seemed to have relieved the painful manifestations the condition of the bones was apparently unaltered.

Mr. W. G. SPENCER suggested that the case might be one of multiple sarcoma, the characteristic features of which would possibly become more manifest later on.

Mr. WALLIS pointed out that it was not unusual for this affection to date from an injury. The patient, he said, was well-known at several London hospitals, and unless the author were in a position to confirm his story, he should be inclined to doubt his history in respect of the injury.

MULTIPLE LIPOMATA.

Mr. BIDWELL showed a strongly built man, æt. 23, who had a tumour in the palm of one hand, and on the neck, ever since he could remember. Seven years ago, something was done to the tumour on the neck, and soon after, several other tumours appeared, and he now presented numerous tumours varying in size from a pea to a walnut, all over the body. The skin over the large tumours was freely movable.

Dr. ABRAHAM said he had made sections of one tumour and found chiefly very vascular fibrous tissue with signs of inflammation. He did not think it could be described as a case of *molluscum fibrosum*.

Mr. CLEMENT LUCAS said some of the larger tumours were probably fatty, but the smaller ones appear to be fibrous.

CONGENITAL ENLARGEMENT OF FOREARM.

Mr. MAKINS showed a young woman, æt. 23, who presented marked enlargement of one forearm. The affection (nævus?) appeared to involve only the deeper veins. He asked whether it was a simple venous nœvus, or one involving the lymphatics. She complained of pain and numbness in the limb, and the swelling was entirely confined to the forearm, not extending into the hand.

Mr. CLEMENT LUCAS said he had no doubt it was a case of veno-lymphatic nœvus, and expressed surprise that she should not have been operated on before. He referred to a patient, a girl between 12 and 14 years of age, who presented this condition, there being a large spongy mass extending from the thigh to the ankle. He excised it in part very freely, and a year later she returned in order that he might repeat the operation in respect of the remainder.

TUMOUR OF MEDIAN NERVE.

Mr. WALLIS showed a young woman, æt. 23, who had sustained an injury to her right hand, damaging the median nerve, on which a tumour formed, which had been operated on several times. In January she came presenting signs of trophic disturbance, due to interference with the innervation of the nerve, in the shape of an ulcer on the index finger and commencing ankylosis of the joints. He excised the whole of the tumour, which measured 2½ inches, and brought the divided ends of the nerve together. She now had a very useful hand, fully capable of being used for sewing, &c.

SUTURE OF TENDONS.

Mr. WALLIS also showed a lad, who had met with an accident resulting in the division of the extensor tendons of the third and little finger, which, after healing of the wound, he was quite unable to extend. He consented to an operation; but as he could not find the upper ends of the divided tendons, he split the lower segments and sutured them to the tendon of the middle finger, and he could now fully extend both fingers with perfect ease.

BRITISH GYNÆCOLOGICAL SOCIETY.

MEETING HELD THURSDAY, FEBRUARY 13TH, 1896.

The President, CLEMENT GODSON, M.D., in the Chair.

Dr. GEORGE KEITH read a paper on

THE PERMANENT CURE OF ANTEFLXION BY OPERATION. which will be found with illustrations, on page 229.

The PRESIDENT, in thanking Dr. Keith for his valuable paper, said that the older methods of treating anteversion by the intra-uterine stem, by Dr. Wynn Williams's pes-

sary, and by Hewitt's cradle pessary were so unsatisfactory as to have been abandoned. The good results of Dr. Keith's operation held out a hope that it would prove a valuable means of treatment.

Mr. SKENE KEITH said that when his brother first described the operation, he did not think it would answer, but once he had seen it he was so satisfied with it that he had performed it since about twenty times. In four out of five cases cure followed, and in the fifth, relief. In the latter class the method was perhaps responsible, he had consequently slightly modified the procedure by making the division more complete and paring off the corners left after division, so as to allow the uterus to assume a straighter position. He thought his brother's method was a real advance in their knowledge.

Dr. HEYWOOD SMITH said that hitherto the explanation of the pain was that it was due to a kink at the internal os. But in Dr. Keith's operation only the lower segment was opened up, suggesting that the pain was probably due to the pressure against the posterior wall of the cervix exerted by the uterus when expelling its contents. He thought that, as a rule, a single dilatation was useless, owing to the tendency to recurrence, but if some kind of incision were made, good results were more likely to follow. He could see no objection to a glass stem inserted for a few days, and he had known this to answer well both for sterility and for dysmenorrhœa.

Dr. BANTOCK traced the history of the treatment of these cases. The earlier methods of bilateral division of the cervix (Sir James Simpson) and incision of the posterior lip (Sims) were not free from risk, and had been given up. The natural history of the dysmenorrhœa was that at first the patient menstruated without pain; later there was some hindrance to the flow of blood, causing a little pain. By repetition, stasis was induced in the uterine vessels, and hyperplasia occurred, causing narrowing of the canal, so that often it would not admit a surgical probe. The pain often became most severe at about the age of 22. He had found dilatation, to No. 16, of the greatest service; if pregnancy followed, the relief was permanent, but otherwise, and in single women, dilatation must be repeated till the patient was cured.

The PRESIDENT said that his experience of the value of dilatation had been remarkable, and he hoped at some time to record his results. The point which struck him was that there were two kinds of ante flexion: one in which the cervix was in a good position and the fundus was flexed forward, the other in which the cervix was at fault, the fundus being in good position. He thought that Dr. Keith's operation would be found to be least satisfactory in the latter class. In his experience, dilatation up to No. 16 gave the best results.

Dr. GEORGE KEITH, in reply, claimed no merit for the operation, which he had learned from Dr. Dudley, of Chicago. When he first heard of it he did not think it would do any good, but after seeing the results of it in Dr. Dudley's patients he changed his mind. By this method the patient could be cured once for all, instead of requiring the repeated dilatations mentioned by Dr. Bantock, and he thought that in the case of virgins especially, this was a most important advantage.

Dr. E. F. ELIOT, of Southampton, read "Notes of Gynecological Cases from a Provincial Hospital," for which we hope to have space in our next.

HARVEIAN SOCIETY.

MEETING HELD FEBRUARY 20TH, 1896.

J. KNOWSLEY THORNTON, Esq., President, in the Chair.

Dr. J. EDWARD SQUIRE read a paper on

SOME CLINICAL REMARKS ON PNEUMONIA.

Dr. Squire first remarked on the influence on the production of pneumonia and on the course of the disease, which is due to the condition of the lung tissue—modifications in the "tissue-soil" which allow of the growth of micro-organisms. It is on the character of this change in the tissues that the "individuality" of each case of pneumonia depends. Though chill is the common determining cause of pneumonia, fatigue or debility after illness render the risks from chill greater. In this connection a case is

quoted where pneumonia followed a chill during convalescence from measles. The not-infrequent occurrence of pneumonia as a complication of enteric fever, introduced some remarks on the importance of deciding in any case of pneumonia whether the lung mischief fully explains the course of the illness as well as the existing symptoms. The occurrence of pneumonia has sometimes delayed the recognition of the disease of which it was merely a complication. The peculiarities of the pneumonia of influenza were referred to, and the influence of malaria on pneumonia was discussed. Whether or not malaria predisposes to pneumonia, there seems little doubt that the cachexia left after malarial poisoning adds to the danger of a subsequent attack of inflammation of the lung. Dr. Squire then considered the question whether acute congestion of the lung occurs, or whether the cases so described are not, in fact, cases of pneumonia. Pneumonia may prove fatal before the lung consolidation is complete, and in other cases resolution of the pulmonary exudation may occur before this has coagulated. In both instances the signs and symptoms of pneumonia are not fully declared, and when recovery takes place in the first stage of the pneumonia process, the term "abortive pneumonia" may be used. Passing on to the course and symptoms of pneumonia, instances of divergence from the usual course of the disease were mentioned, and some of the more important complications and sequelæ were illustrated by cases which had come under Dr. Squire's observation. Pneumonia of the apex sometimes gives rise to difficulties in diagnosis, especially with reference to the presence or absence of tuberculosis. In the treatment of pneumonia, Dr. Squire strongly advocated a stimulant line of treatment from the first. The exhaustion, which constitutes so great a danger, may be more easily prevented than counteracted. The necessity for a plentiful supply of nourishment, which must be administered frequently in small quantities, makes good nursing essential. The good results obtained by the inhalation of oxygen in certain cases, and the relief following a tepid bath in one instance, were also referred to. In conclusion, Dr. Squire remarked that, though we may have some general principles of treatment, which guide us in all cases of pneumonia, the details must depend upon the individual peculiarities of each case.

The PRESIDENT remarked that he hardly ever saw a case of pneumonia in his practice, possibly because when necessary he stimulated very early.

Dr. BOXALL had met with several cases of acute lobar pneumonia in connection with childbirth, cases in which there was not the slightest suspicion of septic complication, and all of them in hospital practice, where the septic element could be completely eliminated. But there are two factors in these cases which appear to have an important bearing on the incidence of the disease, and serve to support the opinion so ably put forward by the author of the paper. (1) The removal of the patient to the hospital during labour entails a considerable risk of chill. (2) The labour itself entails, at any rate in first cases, the hardest day's work which, even in this class of patient, a woman is called upon to perform, and leads to *fatigue*. He had noted the same in connection with pleurisy and acute rheumatism. But these cases, if treated on the now generally accepted lines, all seemed to do well. He had met with acute lobar pneumonia associated with childbirth also in another way. Acute lobar pneumonia, like many other febrile diseases, and especially those known as "acute specifics," often led to premature delivery or to miscarriage. These cases also, if septic contamination be avoided, seemed to do well. It was a point worth noting, that as soon as delivery or miscarriage occurred, not only did the general condition of the patient become no worse, on the contrary, it often improved, but the local manifestation of the disease, the lung consolidation, often rapidly improved also, an effect probably due to the inevitable loss of blood. As regards oxygen inhalations, Dr. Boxall considered them pre-eminently of service as a means of oxygenation when the lung was extensively consolidated, but he wished also to elicit an opinion as to its general stimulating effect. In both ways benefit might be derived.

Dr. G. A. SUTHERLAND referred to the inverted type of breathing which was frequently present in pneumonia, and might prove an aid in the diagnosis of obscure cases.

The respiratory cycle, instead of the normal sequence of *inspiration, expiration, pause*, took the form of *expiration, inspiration, pause*. The fresh air was thus retained in the lungs as long as possible, and the demand for more oxygen was supplied.

Dr. COOK mentioned cases where oxygen had been of the greatest service, noticing, in particular, how its administration seemed to act not only as a stimulant and restorative, but also as an expectorant of great value. He asked if it had been observed that sometimes, in the patchy pneumonia of influenza, the sputum was of a bright sulphur yellow in colour, though scanty in quantity. He remembered that when living in a malarious English district the type of pneumonia was of a particularly fatal character, also mentioning a case of a soldier invalided home for Egyptian malarious fever, who developed pneumonia from a chill, with a rapidly fatal result.

Mr. HAZEL said that he had recently successfully treated a bad case of pneumonia, attended with great debility, in a medical friend, *æt.* 75, who took alcoholic stimulants (whisky and brandy) to the extent of 12 oz. in twenty-four hours; and that he and the patient largely attributed the recovery to their use. In addition, he took strophanthus and nux vomica, which he preferred to digitalis and strychnine; and to aid resolution, iodide of potassium.

Dr. EDWARD GRAY remarked that the paper under discussion reminded him of a case he had about two years ago. His patient, a strong, robust man, *æt.* 30, had passed through all the well-known stages of typical pneumonia which, in spite of treatment, had gradually crept over the greater part of both lungs. There was consolidation of a good deal of the right and apparently the whole of the left lung with effusion into the right pleura. The pulse was of low tension, very rapid and irregular. The breathing also was very quick, shallow and irregular—in fact, he was breathing chiefly by means of the middle lobe of the right lung. The face was livid and the lips blue. Seeing that the case was desperate he determined to try oxygen as a last resource. He drove to Krohne and Sesemann's in Duke Street, and brought back a cylinder containing from 30 to 40 feet of that gas. When he re-entered the sick room, the nurse met him with the remark "Its all over, doctor." He looked at the patient: breathing had ceased and there was no reflex action on touching the conjunctiva. There was no time to examine the heart, but no pulse at wrist or temporal was perceptible. He lost no time in putting the apparatus together and applying the mouthpiece. He then turned on the gas, compressed the patient's chest at regular intervals, and eventually perseverance was rewarded by respiration being re-established. The patient gradually improved from that hour and is now as well and strong as ever he was. Dr. Gray added that with regard to the colour of the expectoration in pneumonia following influenza, that he was at present attending a case, and was much surprised at the long continuance of what he took to be the characteristic rusty-coloured sputa. A day or two ago, however, he found on inquiry that his patient had been in the habit of sucking "Spanish liquorice" for the relief of the cough. It was quite possible, therefore, that her expectoration had taken on the yellow colour alluded to by Dr. Cook from this cause. The fact, he thought, was worth remembering as showing how necessary it was to make minute inquiries and accurate observations.

Mr. SPENCER HUELBUTT agreed with Dr. Squire that pneumonia following influenza differed in many respects from the ordinary lobar variety; it was especially in these cases that the early and free use of stimulants were required. He inquired in what stage of pneumonia was the inhalation of oxygen most likely to be of service?

Dr. CAGNEY spoke of the advantage of administering oxygen by inhalation in pneumonia and in cases of heart failure from other causes, illustrating these points by the mention of cases within his experience.

Dr. SQUIRE then replied to the various questions and points raised, and the meeting adjourned.

Dr. GRANVILLE BANTOCK, F.R.C.S.Ed., Senior Surgeon to the Samaritan Free Hospital, having resigned that post, has been elected on the Consulting Staff.

THE LARYNGOLOGICAL SOCIETY OF LONDON.

MEETING HELD FEBRUARY 12TH.

DR. FELIX SIMON, President, in the Chair.

DISCUSSION ON THE NATURE OF LARYNGEAL COMPLICATIONS OF TYPHOID FEVER.

THE discussion was opened by a paper by Drs. KANTHACK and T. A. DRYSDALE.

Dr. KANTHACK, who read the paper, began by stating that opinions differed considerably with regard to the frequency of intra-laryngeal ulcerations during typhoid fever. Out of 61 fatal cases at St. Bartholomew's ulceration was found in 26 cases. The general situations were the tip and edges of the epiglottis and in the neighbourhood of the vocal processes. With regard to the pathological nature of the lesions, Are they specifically typho-genetic? The assumption that the ulcers are decubital was at once set aside as erroneous. That they are produced by repeated injuries acting on debilitated tissue was more commended. That they were typho-genetic on the ground that the ulceration affected the adenoid tissue of the larynx is incorrect, as in the above regions no such tissue exists. That the evidence of the assumption from analogy of other parts, such as periostitis and parotitis, that the typhoid bacillus produces the ulcers is weak and insufficient. The bacteriological evidence is very incomplete, and such as there is points against their specifically typho-genetic nature. Clinical evidence too does not support the theory, as there seems to be no relationship between the symptoms of the fever and the laryngeal lesions. The explanation that the mucosa of the larynx being in the so-called "typhoid state" is readily injured and forms an easy portal for pyo-genetic cocci, and naturally this occurs most commonly in the most inefficiently vascularised portions, however, does not satisfy all cases. The lesions are undoubtedly caused by micro-organisms, and there is the strongest evidence that these are the pyococci, and with very rare exceptions the typhoid bacillus.

Dr. WATSON WILLIAMS (Bristol) was of opinion that while acute and chronic laryngeal lesions are sometimes undoubtedly secondary, the result of septic infection, they are in the main specific, and due to typhoid toxin, and more frequently associated with the presence of the Eberth bacillus than Dr. Kanthack's observation had led him to believe. Dr. Williams submitted the following reasons for arriving at this conclusion: 1. As regards lymphoid tissue, Cornil and Ranvier had found that, while in typhoid cases dying from pulmonary and bronchial complications catarrhal laryngitis was generally present, in a smaller portion, and in a more acute form of laryngitis, the lymph follicles were tumefied and formed nodules, in which the multiplication of the nuclei and infiltration of the retiform tissue were entirely similar to what is observed in the closed follicles of the small intestine. These tumefactions often give place to crateriform ulcers. 2. The frequency of initial lung symptoms in typhoid were suggestive of a specific origin, and, in fact, the typhoid bacillus had been found in the lungs in numerous instances. Newman found the typhoid bacillus in 11 out of 48 cases in the kidney, and concluded that the bacilli appeared only in the urine when the kidney is directly involved. Thus the preliminary and renal lesions should be regarded as due to the typhoid bacilli and their toxins. 3. The frequency and the characteristic aspect of laryngeal ulcers in typhoid, as compared with the rarity in other exanthemata, pneumonia was strong *prima facie* evidence in favour of their specific nature. In congenital typhoid the intestines do not present ulceration, due, Dr. Williams thinks, to the absence of saprophytic micro-organisms, especially the B. coli, which, abounding in the intestinal tracts in after-life, add to the virulence of the typhoid bacillus. So in the larynx, the ulcerative process may be due to its exposure to the combined action of these bacilli, under conditions which markedly favour the development of extreme pathogenic properties. 4. It was hardly possible to account for the inoculation of certain cases, except by serial infection. Dr. Williams referred to cases in which typhoid was apparently caught from the expectoration of a case with laryngeal ulceration. These cases were virulent and fatal. Two had laryngeal ulceration, and in one case, Eberth's bacilli had been obtained from

these ulcers. 5. Just as more general typhoid lesions fell into two groups—the acute and the chronic, secondary focal abscesses, otorrhoea, osteomyelitis, in which typhoid bacilli had been demonstrated, so, likewise, did the laryngeal complications of typhoid fever.

Mr. S. G. SHATTOCK exhibited some preparations showing the ulcers so typical in situation, viz., over the vocal processes of the arytenoids. He could say from having examined especially into the point, that there was no lymphoid tissue in this situation in the normal condition. Therefore, the lesions in the larynx were not strictly comparable to the intestinal lesions.

Dr. J. HORNE said that ulceration of the larynx in typhoid fever was necessarily of a typhoid origin. In some cases, the ulceration had been found *post-mortem* to be tubercular. In such cases, it would be important to know the state of the lungs and larynx before the onset of the fever. Bearing in mind that tuberculosis more commonly follows typhoid than any other fever, it may be that typhoid renders the laryngeal tissues more vulnerable to the attacks of the tubercle bacillus.

THE PRESIDENT asked why the cricoid cartilage was so frequently the site of the disease? There were several specimens showing this without disease at the processus vocalis.

Dr. KANTHACK, in reply to Dr. W. Williams, did not accept the statements with regard to lymph follicles in the larynx. His own and other observations showed the absence, even in disease, of adenoid tissue on the vocal processes and on the tip of the epiglottis. He desired to know what authority Dr. Williams had for stating that the typhoid bacillus had been found in the lungs in numerous instances. The presence of Eberth's bacillus in the blood during typhoid was generally acknowledged to be extremely rare. Its frequent occurrence in the urine was indisputable, but this was no argument that the tissues were generally infected. To argue from congenital typhoid was to argue, in his opinion, from the unknown. Dr. Williams assumed that the typhoid bacillus in the lungs produced no ulcerative lesions because it did not co-exist in the B. coli. Dr. Kanthack, on the other hand, had shown that it was always there, and in following Dr. Williams' own argument, necrotic lesions in the lung should be common in typhoid. Most authors had failed to find typhoid bacilli in suppurative and inflammatory complications of typhoid. With regard to the President's question, he was not prepared to answer without a little more thought and study, but he had always considered the cricoid perichondritis to be secondary to the ulceration on the processus vocalis.

DISCUSSION ON FOREIGN BODIES IN THE UPPER AIR AND FOOD PASSAGES.

Mr. C. SYMONDS, in opening the discussion, said that in the nose, when no history was given, the most characteristic symptom was unilateral purulent, often blood-stained, discharge, with more or less obstruction. Young children should be examined under chloroform, and the foreign body removed with forceps or probe. In the pharynx stress was laid upon the importance of examination with the mirror, and the close resemblance of a string of glazy mucus to a fish-bone. Where nothing could be seen the finger should be used. The danger of thus driving in sharp bodies was referred to. In the larynx division was made into those that were small and did not impede respiration, and those that were large and obstructive. In the first case, intra-laryngeal methods of removal were recommended. In the second group great stress was laid upon the importance of having everything ready for tracheotomy, in case of spasm occurring. If the body is impacted in the glottis, after tracheotomy, he considered it better to attempt at removal through the mouth by a skilled operator before dividing the thyroid cartilage. He would not retain the tube after all extraneous substances were removed. In the trachea and bronchi the value of the paroxysmal cough was referred to, also the importance of the knowledge of the nature of the foreign body. The danger of mistaking the quiet period for complete recovery was pointed out. The danger of inversion and succussion, without previous tracheotomy, was thought to be sufficient to exclude the method. Tracheotomy should always be performed if a foreign body were in the trachea or bronchi. In the oesophagus

phagus the main point was the danger of over-manipulation, causing fatal laceration, driving penetrating bodies into the œsophagus, and the wisdom or otherwise of pushing down impacted food, rather than waiting a few hours for solution to take place. Importance was attached to the sounding for coins, and the inadvisability of using an ordinary bougie. For the removal of tooth-plates œsophagotomy was recommended, the wound to be packed with gauze after suturing the gullet.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD THURSDAY, FEBRUARY 13TH, 1896.

The President, Dr. PORTER, in the Chair.

PROFESSOR HICKS, F.R.S., Principal of Firth College, gave a very clear and interesting account of his experiments with Röntgen's rays, of which we gave a description in our issue for February 19th. He showed a large number of sharply-defined and beautifully executed shadowgraphs.

Dr. ARTHUR HALL showed: (1) a case of facial spasm; (2) a case of osteo-arthritis, with Röntgen shadowgraph of one hand.

Mr. DALE JAMES showed (1) a case of "Circumscribed Scleroma" in a girl, *æt.* 19. The patch existed as an arc four inches long upon the upper surface of the left mamma. It followed a severe blow upon the site four years before. Under massage and the constant current, it was rapidly improving. (2) A severe case of "Raynaud's Disease." The patient was a woman, *æt.* 44. When first seen, a fortnight before, the fore half of each foot was deeply cyanosed, and mottled patches extended above the outer arch of the left leg. Both arms were similarly mottled to the shoulder on the extensor surfaces. The right hand was cold, purple, and œdematous. The left presented an extraordinary appearance. The fingers were greatly swollen, of a brilliant scarlet colour, spotted with white; the index and second fingers showed hard necrotic plugs, destroying the entire pulp. These have since broken down to some extent, but are not yet detached. A former attack, six years ago, was not so severe, but involved some of the toes in superficial ulceration. There is no evidence of specific taint, although she has miscarried twice, having four living children. She had rheumatic fever eleven years ago, which has left a slightly damaged aortic valve. The present attack commenced in September, after a miscarriage.

Mr. CHARLES ATKINS showed a case of

SYMMETRICAL GANGRENE—? RAYNAUD'S DISEASE.

Mr. C. B., *æt.* 39, complains of the tips of the fourth and fifth digit on each hand being cold and dead: one month. One month ago, when employed at work in a cold and damp cellar, he became ill with a severe cold (? influenza). Had pain like rheumatism in his fingers and then they became cold, and of a purple colour, turning to a deep dead black, down as far as first joint, except fifth digit on right hand, which is only affected just at the tip; the parts just above the line of demarcation are slightly swollen, inflamed, and tender. Both feet have been affected with discolouration, extending from centre of foot on outer side round the heel to a point opposite on the inner side. The toes have also been slightly discoloured and painful on the dorsum. When 15, had rheumatic fever. No other severe illness of any kind. No history of syphilis. Has had slight (?) rheumatic pains on and off last three years. Has had very good health. Father died, *æt.* 70, of hepatic cirrhosis. Mother alive and well, *æt.* 56. Seven sisters, all alive and in good health. One brother, ditto. No family history of any complaint. Heart normal. *Urine*—Clear, acid, 1020, alb. $\frac{1}{2}$. No sugar.

Dr. SINCLAIR WHITE showed

(1) A woman, *æt.* 50, who had a cancerous stricture of the rectum of six years' duration. Colotomy had been performed three years after the onset of symptoms. The patient was still fairly well and might be expected to live several years yet.

(2) A man, *æt.* 69, whose rectum had been resected nine months previously for cancerous stricture situated three inches from the anus. The growth together with five inches of the rectum was removed by the trans-sacral

incision. The peritoneum was freely opened and the growth drawn out of the wound. A Murphy's button was used to unite the ends of the rectum. The posterior part of the rectal wound leaked, and for a time there was a fecal fistula, but this gradually contracted. There was no evidence of recurrence, and he had complete control over his sphincters. He had gained two stones in weight since this operation, and was stronger than he had been for years.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, Feb. 29th, 1896.

ANTI-DIPHTHERITIC SERUM.

At the last meeting of the Société Médicale des Hospitiaux M. Hutinel read a paper on this subject. He said he considered Roux's serum a marvellous remedy, and invariably employed it in diphtheria of any gravity. He thought it, however, necessary to subscribe to the two following propositions set forth by M. Sevestre.

When a diphtheritic angina of benign aspect develops in a child, the subject of enlarged chronically inflamed tonsils and adenoid vegetations it is better not to commence injection of serum, unless examination reveal the presence of Löffler's bacillus of the long variety, and in great numbers, or unless the membranous fœces be affected.

And again, in cases of scarlet fever, when the bacillus of Löffler is discovered in the throat, it is best to make sure before injecting if the bacilli are long and numerous and the diphtheria clearly characterised.

For a long time M. Hutinel has held the opinion that the more serious of the complications following injection of serum ought not to be ascribed exclusively to the serum nor to the antitoxin which it contains, but rather to secondary infections. These infections are probably due to streptococci. The presence of streptococcus, even of the virulent type, in the throat, is not, however, reason sufficient to make that organism responsible for the complications which may follow injection of serum. In cases of undoubted streptococcus he has often sought in vain for that organism in the blood.

He has considered whether chronic inflammations of the throat, before onset of diphtheria, were not in some way associated with complications following sero-therapy. He has observed that the most serious manifestations were usually produced in children with large tonsils, with chronic inflammation, and with adenoids, and he thinks that the specific germs may develop in the crypts and cavities of the parts.

A recent case of death in a girl, *æt.* 12, suffering from diphtheria and streptococcus has confirmed him in his belief in the greater gravity of cases of the above kind; and he has records of other cases in which, as in this, after injection there supervened albuminuria, anuria and death. M. Chantemesse thinks that no one with any experience can believe that complications of any more than slight importance ever follow serum injection; and does not believe that albuminuria is ever so caused. He believes, on the contrary, that the serum protects the kidneys; and that when albuminuria occurs, it is almost always due either to the diphtheritic infection itself or to an infection by streptococci. He criticised cases in which albuminuria had been ascribed to injection of 10 cc. of serum, and asked if so small a dose were capable of giving rise to this complication; whether cases would not be much more commonly met with; and it was well known that the most

minute examination in many cases failed to show the slightest trace of albumen. M. Variot, who has had a vast experience in this matter, has never seen a case of albuminuria which he could ascribe to serum, nor has he ever observed any effect on the kidneys, save an almost constant diminution of the quantity of urine secreted during forty-eight hours.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, Feb. 28th.

TUBERCULOUS PERITONITIS.

PROF. ISRAEL, in a contribution on the above-named subject, reports 4 cases successfully treated by operation. Three of them were children from 4 to 7 years of age, and one was a girl of 20. In the first 3 the diagnosis was arrived at before operation and confirmed microscopically. The time that had elapsed after the operation was 17, 16½, and 7 months respectively. The only new feature about these cases was that before closure of the abdominal wound a quantity of iodoform oil emulsion, 10 per cent. in strength and from 10 to 30 grammes in quantity, was poured into the abdominal cavity. He thinks the cure of tubercular peritonitis cannot be explained by the removal of the ascites that goes along with the laparotomy. In spite of the presence of tuberculous ulcers of the bowel permanent recovery may result from operation. Even within 36 days of the operation all tuberculous nodules, even those the size of a cherry, may have disappeared. Fever is not a contra-indication of the operation.

In the fourth case there was tumour-like tuberculosis of the ascending colon. On account of the extensive dissemination of tubercle in the peritoneum, no attempt was made on the tumour-like growth, but an anastomosis was made between the colon and the ileum, 10 cm. nearer the anus than the tumour. Recovery uninterrupted. The tumour diminished so much in size after the operation that at the time of writing it was no larger than a walnut.

REGULAR PHENOMENA IN THE SPREAD OF SOME ENDEMIC DISEASES.

At the Hufeland Society Hr. A. Goffstein read a paper on this subject. After a definition of infection, he said that in the case of tuberculosis something more than the excitator was necessary to the production of the disease—a certain condition of the organism or disposition was necessary, and this had nothing to do with the pathogenic germs. The necessary factor was at first denied, but later it had to be conceded, and not only for tuberculous, but also for diphtheria and cholera. It was especially due to Liebreich, by the introduction of the idea of *noso-parasitism*, that we had an explanation of this question. In order to understand the processes in the spread of infective diseases, we must not only consider the bacteriological aspect of the subject, but also the receptivity of the individual, for on this factor alone depended the mode of the extension of the disease. If contagion alone was all sufficient, enormous numbers would sicken in a short time, as in the case of small-pox, measles, and *var typhus*. The spread of an infective disease was quite different when the population was not susceptible. Here the rise of the curve would be much slower, it would never reach the height of that of the other disease, and its fall would be much slower. If this were applied to the spread of an epidemic it would follow the more general the re-

ceptivity for infection, the more rapidly would the epidemic spread and die away, and *vice versa*. The amount of this receptivity was determined by reckoning how many out of 100 people coming into contact with the infection would later on be attacked with the disease. This number he had named the contagion index, and he had attempted to fix it for measles, scarlatina, and diphtheria.

As regarded measles, of 100 children coming into contact with the infection, 95 would take the disease, so the contagion index would be 0.95. From numerous data, he had determined that in the case of scarlatina, the contagion index was 0.4, and for diphtheria, 0.1, *i. e.*, of 100 children exposed to the infection of scarlatina, 40 would contract the disease, and in the case of diphtheria, 10. According to this the courses of the three epidemics must be very different from each other. The curves of measles epidemics must be very abrupt, there must be a sudden rise and a sudden fall. The curves of scarlatina epidemics must mount more slowly, they could never reach the height of those of measles and the fall must be more gentle. The diphtheria curve must be flatter still and the time from the commencement to the highest point and to the final fall might perhaps cover decenniums.

The importance of these considerations was not seen in the material of the smaller towns, as epidemics were prematurely extinguished for want of material. As objects of study only towns of 100,000 and upwards would be taken, and the curves could only be constructed from the mortality as no other data were accessible.

The speaker then showed his curves relating to these diseases in fourteen of the chief cities of Europe. They were uncommonly characteristic and showed that similar conditions prevailed in all the towns. A peculiarity of the measles curve was that all the greater epidemics began in the second quarter of the year. Another peculiarity was that the outbreak began in many towns in the same quarter of the same year.

As regarded scarlatina a period of 10 years was too short to allow more than one epidemic. It was lighted up in these towns about every 10 or 15 years, and the descending curve was generally more abrupt than the ascending one. The duration of a curve was 3 years and upwards. It was of no use to give a 10 years' curve of diphtheria; those of Heubner and Hecker were only fractions of a whole, and were, indeed, the tolerably steep ascending limb of a curve, the summit of which was reached in the first half of the "Eighties." [Sclava had shown this fall for Italy, and it was incomprehensible how Behring had brought him forward as a witness for the constancy of diphtheria. To get a characteristic curve for diphtheria one must take a period of over a quarter of a century. The speaker then showed 25-year curves for diphtheria for Berlin, Leipsic, and Dresden. The curve rose irregularly, suddenly reached a high point, and then fell with terrace-like gradations. All the large cities of Germany were in the terrace stage of decline long before the introduction of Behring's serum. London alone, where the acme was reached later, *viz.*, at the end of the Eighties, had in 1895, in spite of serum, a mortality almost equal to that of the worst period. The study of diphtheria epidemics then required, not decenniums, as in the case of measles and scarlatina, but centuries.

From the study of the history of diphtheria, we learned the surprising fact that an epidemic of diphtheria extending over decenniums follows upon a period equally long, in which nothing is heard of the disease, that whole genera-

tions of physicians did not know the new disease that had sprung up.

In Europe the contagion first appeared in Spain at the commencement of the 17th century; it reached its height in 1613, and played an important part in Spain, England, and Italy in the first half of the century. Just 100 years later it again appeared, and devastated the peninsula, and about the end of the Forties attacked England, France, Italy, Switzerland, and Sweden. It appeared first in Germany in the latter half of the century, and in 1798 was spread over the whole of Europe. At the commencement of this century it appeared in Eastern Europe, and in East and Mid-Germany. In the second and third decenniums it was almost confined to France, where Bretonneau published his classical work. From then to the commencement of the Fifties it completely subsided in Europe. This disappearance only lasted 15 years in France, but in Germany a whole generation, and for the Netherlands half a century. Just before the middle of the century diphtheria again began its march through Europe, reached its highest point, as already stated, about the end of the Eighties, from which date a distinctly recognisable eubidence has taken place. In Berlin the disease first appeared in a noteworthy manner at the commencement of the Sixties, reached its highest point in 1883-4, and since then has steadily subsided. Whether the epidemic will become extinguished, whether it will become epidemic in the great towns, with periods of exacerbation and retrogression, the next twenty years will teach us with greater certainty.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, Feb. 23th, 1896.

BURNS.

KAPOSI showed to the Gesellschaft at the last meeting a young man with a deep burn on the hand which he considered of great importance, as it exhibited a condition of charring of the tissues unusually met with. The patient was fifteen years of age, and was engaged with a butcher. On January 15th, he met with the accident, and on the following day was brought to the clinic, when it was found that the skin and soft tissues of the left arm were charred to the elbow, while the injury to the right was confined to the back of the hand. In the hard mass the subcutaneous veins could be distinctly seen coursing under the surface. There were no secondary phenomena which usually accompanied deep injuries of this character. No albumen in the urine, no pain, nor other toxic symptoms. A few days later it was discovered that the skin, subcutaneous fat, and tendons had been quite destroyed by the heat, since the capsules of the joints soon sloughed, the ends of the bones extruding. In closely examining the cause of this lesion several difficulties present themselves, as the history leaves us to conjecture the cause. In the case of females where clothing has taken fire, and produced severe burning, we are often able to trace the lines on the body where the hard parts of the stays have been in contact with the surface which, owing to their greater capacity for heat, have produced local charring. This boy's duty was to attend to the fire on which large quantities of refuse were kept constantly burning. It is presumed that at the time of the accident, the lad's hands and arms of his coat were covered with fat, which

has also a great capacity for heat, and may probably be accounted for the severity of the lesions. It is also presumed that he had taken a fit as we learn he had three epileptic attacks in the preceding year. All the information we can glean from the lad is that he had fallen asleep by the fire and that he was awakened by the smarting sensation of the heat. It is possible that this so-called sleep may have been equivalent to an epileptic attack.

ALLOXURINE BODIES.

Kolisch followed Kaposi with a reply to Zülzer, of Frankfort, who has challenged the correctness of the results in a paper which the former read a few months ago before the Gesellschaft. In that address on the morbid conditions of gout Kolisch placed the maximum value in perfect health of the nitrogenous bases at 0.06 which seems to have been in close accord with Leyden's result, which was 0.07. Any variation from this was classed as a pathological disturbance, which might rise as high as 0.1 or 0.12, or double the maximal normal result. Zülzer now affirms that this nitrogenous base is very much lower than what Kolisch has reckoned it, and quotes six cases where it was absent. Kolisch produced a letter from Krüger, who first introduced this method of inquiry, and affirms that Zülzer has erred in his analysis. In the discussion that arose, Freund related twelve cases of Morbus Brightii in which the alloxurine bodies had been carefully separated; eleven gave the exact results recorded by Kolisch. The remaining case seems to have been affected by the diuresis.

MYXŒDEMA.

At the Medical Club, Hock exhibited a child, 21 months old, with typical myxœdema, which he had treated with the thyroid extract. Alongside with this patient he placed an idiotic child four years of age, whom he had treated with the same preparation, with satisfactory results. He thought it ought to be more generally known that thyroïdin was as efficacious in the idiotic as in myxœdema.

Prof. Kassowitz related a case of cretinism and myxœdema combined, which improved wondrously under the thyroid treatment.

He admitted that the intelligence remained unchanged, but the other symptoms were greatly improved. He also added that cretinism was more general in Vienna than at present recognised. The differential diagnosis from idiocy was the vaulted condition of the mouth or the thorus palatinus. To this Köhn said that he had often seen cases with thorus palatinus and not a trace of cretinism present. Kassowitz admitted this was possible, but he would never meet with a case of cretinism without the thorus palatinus.

IODINE IN THE THYROID.

Töpfer brought the recent results of Baumann before the Gesellschaft by stating that the normal gland contained iodine, which was firmly bound up with the organic matter, but after boiling with sulphuric acid could be separated. Baumann macerated the gland from 4 to 8 hours in a 10 per cent. solution of sulphuric acid; the solution was then filtered, and treated with alcohol, he afterwards obtained iodine by evaporation, varying in amount from 9.3 per cent. Baumann has named this "Thyroid Iodine." This he thinks accounts for the absence of iodine in the fluids of cretins and strumous patients.

THE Duke and Duchess of York will visit Halifax on July 21st, in order to open a new Infirmary which has been built at a cost of £80,000.

The Operating Theatres.

MIDDLESEX HOSPITAL.

LYMPHATIC NÆVUS OF THE TONGUE (LYMPHANGIOMA).—Mr. BLAND SUTTON operated on a countryman, æt. 40, who was sent in with an elongated raised patch upon the left side of his tongue measuring seven centimetres in length, and two centimetres in breadth, the long axis of the patch coinciding with the long axis of the tongue. In colour the tumour resembled a patch of xanthelasma, but the uniformity of its surface was broken by small cysts the size of millet seeds. The man stated he had had this tumour for ten years, but lately it had been getting much larger. When touched roughly with a towel its surface bled. There was little doubt that the tumour was a lymphatic nævus. It was freely removed with the knife and about fifteen vessels required pinching or ligature; some of these were compressed and others tied with fine silk and the edges of the wound brought together by sutures. Mr. Sutton remarked that this was a rare species of tumour, the usual form being known as macroglossia; of course, he said, it is well known that all navi of the tongue as of the skin contain lymphatics, but in some of these tumours the lymphatics preponderate over the hæmic capillaries and then the growth is called a lymphatic nævus, but this condition of things is excessively rare, blood vessels, however, were not absent in the one just removed as the exceedingly free bleeding demonstrated. The cut surface of the tumour exhibited a structure exactly resembling that of a corpus cavernosum or spongiosum. Mr. Sutton further stated that the clinical distinction between a nævus and a lymphatic nævus of the tongue was simple as the former was deep blue, like an ordinary venous nævus of the skin, but the latter was colourless and resembled a patch of xanthelasma.

CHELSEA HOSPITAL FOR WOMEN.

CHOLECYSTOTOMY.—Mr. BLAND SUTTON operated on a woman, æt. 40, who had been admitted with acute abdominal pain, vomiting, and jaundice; she was very fat, and had an umbilical hernia, and for some hours it was conjectured that the bowel was strangulated in the sac. When he saw the case the sac was soft, and its contents easily reducible, and this disposed of the idea that the hernia was strangulated. The jaundice and the acute pain which the patient felt in the region of the gall bladder made him think that gall-stones were the source of trouble. An enema was prescribed, and a subcutaneous injection to relieve the pain. The patient stated that she had had an attack three months previously, and ever since felt pain just below the right costal arch; she was watched for a few days, and Mr. Sutton came to the conclusion that she had gall-stones impacted in the cystic duct, and occasionally that the stone interfered with the passage of bile from the hepatic duct. The woman was recommended to submit to operation. The gall bladder was exposed by a longitudinal incision in the right linea semilunaris, and found enlarged and its walls thickened; the cystic duct contained a number of small calculi. The fundus and the gall bladder was incised, and the calculi, manipulated by the fingers, were conveyed from the cystic duct into the gall bladder, and from thence extracted with a scoop. The fundus of the gall bladder was sutured to the peritoneum, and the incision closed in triple layers. Mr. Sutton said the interest of the case was two-fold: In the first place, the diagnosis that the calculi were lodged

in the cystic duct was confirmed; and secondly, the concretions were of peculiar shape inasmuch as they were the size of green peas, but tuberculated in all their contour, like mulberry vesical calculi.

Forty-eight hours later the patient was absolutely free from pain and jaundice.

ST. THOMAS'S HOSPITAL.

SUPRA-PUBIC CYSTOTOMY.—Mr. BATTLE operated on a man, æt. 72, for stone in the bladder. The patient had been attending as out-patient for symptoms of enlarged prostate with cystitis and a stone had been discovered on sounding. The symptoms had commenced some months before but had recently become worse. On admission he had most of the usual signs of stone but without hæmorrhage; there was a small amount of pus in the urine and a little mucus. As there could be no doubt of the presence of a stone he was kept in bed for a few days and no instrument passed. His symptoms improved and his general health was better by the time of operation. After the administration of ether a lithotrite was passed, the presence of the stone immediately detected and its size at once ascertained. As it measured more than an inch-and-a-half it was decided to remove it by the high operation and not by lithotritry. It was considered that the crushing of a stone of this size would take a long time, and in a patient of his age this would be a serious consideration, and besides it was not possible to say what the consistence of the calculus might be. The bladder would not hold more than four ounces of boracic lotion, and although the rectal bag was introduced this did not cause the bladder to rise more than about two inches above the pubes. A median incision was employed and the bladder exposed; the fold of peritoneum came low down, but was easily pushed upwards. The surface of the bladder was covered by a network of varicose veins unusually numerous. Two ligatures were passed through the wall of the bladder on either side of the middle line and the viscus opened between; a large stone was immediately felt lying behind the prostate, and it was necessary to enlarge the opening in the bladder considerably before it could be extracted. It broke in two parts during extraction, and was seen to consist of a central nucleus of oxalate of lime with a thick coating of phosphates. It measured two inches in its longest diameter, and an inch and a half across. The walls of the bladder were somewhat hypertrophied, and the mucous membrane showed signs of chronic inflammation. The prostate was hypertrophied, but there was no special projection of any one part. The bladder walls were stitched on each side to the skin; a special drainage tube (resembling a tracheotomy tube) was passed to the bottom of the bladder, and the upper part of the wound closed with silk stitches. A dressing of cyanide gauze was then applied, and on return to bed a long tube was passed into the drainage tube already in position to carry the urine into a utensil by the side of the bed. Mr. Battle remarked that the size of the stone and the hard character of the nucleus proved that its removal by lithotritry would have been somewhat difficult and required too much time; whereas the operation performed took about half an hour, the lithotritry would have taken an hour or an hour and a half, and the advantage of drainage to the bladder would have been lost.

THE deaths from diphtheria, which had been 61, 63, and 45 in the preceding 3 weeks, rose again last week in London to 48, exceeding the corrected average by

WEDNESDAY, MARCH 4, 1896.

DEVELOPMENTAL HEART DISEASE.

It is a well-known clinical fact that certain varieties of heart disease are associated with the growth of the organism, but the pathology of the subject is still characterised by a vagueness which is not conducive to the success of therapeutical measures. It is evident that rapid growth must throw an extra strain on the heart as the distributor of the elements which go to maintain the tissues and to provide the materials for their development. It is evident that the presence of congenital cardiac lesions interfering with the distributive function of the heart necessarily retards growth, and, on the other hand, a heart which has been able to fulfil all requirements up to a certain point may, when a sudden strain is thrown upon it by the supervention of active growth, as at puberty, develop functional disturbances and bring to light previously unsuspected sources of cardiac weakness. During these periods of rapid growth the heart undergoes a physiological increase of size, which might be called hypertrophy were it not for the fact that hypertrophy is a term indicative of something abnormal. It is under these circumstances that the heart, which is hereditarily prone to abnormal or irregular development, first gives evidence of its tendency. Cardiac defects at these periods of growth may arise then, either from develop-

ment along abnormal lines or to more or less partial arrest or imperfection of development. Organic murmurs are met with at these periods with tolerable frequency. Rare in new-born and suckling infants, they increase in frequency with the advance of age up to the fifteenth year, when for a time they undergo a diminution, only to resume their sway at the twentieth year of life. They are met with more frequently in boys than in girls, and seldom in children of good health. This liability of the heart to develop latent tendencies at particular periods is well shown in the lesions associated with the rheumatic diathesis. It is essentially during the periods of rapid growth that we most frequently meet with evidence of cardiac mischief of the kind which accompanies or follows rheumatic manifestations in any form. One of the difficulties of the subject arises from the fact that the growing heart is peculiarly liable to undergo dilatation under comparatively slight provocation and also that disturbances of cardiac innervation are liable to arise from reflex or other adventitious causes. Practitioners are familiar with phenomena of this class due to undue physical exertion during adolescence and other disturbing causes are the early use of tobacco and disturbances of the gastric functions. Then, too, the adolescent heart appears to be peculiarly susceptible to the influence of infective agents, and the influence of these agents may accentuate and make evident inherent weaknesses of structure. The comparative abundance of lymphoid tissue in the growing heart renders it especially amenable to toxic influences of this kind. Considering the large number, not only of infectious diseases but of infective states, to which a child is exposed, it is evident that the heart must be frequently attacked. Apart from rheumatism, measles, and other common febrile complaints of infancy and adolescence, the growing child is subject to influenza, acute dyspepsia, febrile attacks with swelling of the lymphatic and febrile attacks not possessing any definite characteristics. All these affections are determined by, or at any rate associated with, toxic or infective phenomena, capable, under particular conditions, of exerting an injurious effect on the heart. Many of these disturbances being ephemeral, often escape recognition and when discovered may excite surprise by their sudden disappearance. The disappearance of the clinical signs, however, by no means implies that the heart has resumed an absolutely normal state, though the process of growth, as all clinical observers know, favours recovery. Nevertheless, these disturbances may not improbably pave the way to subsequent disease of that organ. This, as Dr. Springer aptly observes in a recent article in *La Semaine Médicale*, is not merely a hypothesis, for, as he points out, the occurrence of an attack of endocarditis after an infectious disease renders the heart more prone to subsequent infection. All children contract infectious diseases but all do not develop heart disease. This is due to the fact that the lesion becomes localised in an organ predisposed to it by hereditary influence. Under these circumstances there is a tendency to fibroid degeneration which, rarely

observed in new-born infants, becomes more frequent and more marked as the period of growth is approached and it is especially towards the close of the period of growth that they supervene, for, in proportion as the strain of growth loses its preponderance, heredity resumes its sway.

DR. ARMSTRONG AND THE TYNE PORT SANITARY AUTHORITY.

At the end of last January the Tyne Port Sanitary Authority received its annual report under circumstances that demand something more than mere passing comment. The document in question was drawn up by Dr. Armstrong, although his resignation of the post of the medical officership had been previously accepted by the authority. It contains a summary of the circumstances that led up to his withdrawal, and is probably unique in the history of official sanitary reports, as it contains a serious indictment of those responsible for the local government of the Tyne Port. Opinions will doubtless differ as to the entire wisdom of the course adopted by its author in availing himself of the accident that placed so powerful a Parthian weapon in his hands. He may be reminded, perhaps, that his report may not only fall short of an ultimate position, but may even turn out to be many times removed from the penultimate. In disputes of this kind the exact advent of the "last word" very much depends on the strength and temper of the opponents. However, in this particular case Dr. Armstrong appears to have been badly treated, and as the whole affair involves principles of importance in the future of public health administration it may be well to review briefly the leading features and bearings of this Northern *casus belli*. For many years past Dr. Armstrong has done extremely good and progressive sanitary work as Medical Officer of the town of Newcastle-on-Tyne. To that post he united, naturally enough, as it will seem to most people, the Medical Officership of the neighbouring authority of the River Tyne Port. The latter includes Gateshead, Tyne-mouth, South Shields, Jarrow, and an area that may be broadly defined as comprising the seaboard, river, and river banks, at and about the mouth of the Tyne. It will thus be seen that the Tyne Port Authority holds the key to the shipping traffic as it passes on its way to the great commercial centre of Newcastle. Some idea of the extent and responsible nature of the duties discharged by the down-river Board may be gathered from the Report for the year 1895. During the twelve months in question, no less than 11,757 vessels were inspected, and of these 1,381 were found defective. The total number on board the 11,757 inspected vessels, including crews, passengers, and emigrants, amounted to 173,782 persons. 520 vessels were boarded on account of their coming either directly or indirectly from foreign ports infected with cholera or small-pox; while a further 239 came from places suspected of similar infection. Turning next to diseases reported on shipboard during voyage, on arrival, or whilst in the River Tyne Port, during the year 1895, we find 9 cases of small-pox, 21 of

cholera (all of them on the voyage); 143 of diarrhoea, choleraic diarrhoea, and suspicious cases; 12 of enteric fever; 17 of malaria; 38 of yellow fever (all on voyage); and 27 of fever and ague. It is from these returns that the importance of the preventive work done at the mouth of the Tyne will be mainly apparent. The arrest of cases of cholera at the seaports, whereby they are prevented from going inland to act as centres of infection, is now recognised to be a preventive step of nothing less than national importance. Indeed, it may be asserted without fear of serious contradiction that had no other function than that of cholera prevention been performed by the Port Authority since its foundation, that work alone would have fully justified its existence. Now, the whole of the excellent system of inspection and control of the port shipping has been organised and administered by Dr. Armstrong, who some years since, when cholera raged on the Continent, rendered important service to the nation by the rigid and admirable sanitary *cordon* which he established at the entrance of the Newcastle waterway. It is, therefore, to be regretted that anything should have arisen to disturb the hitherto harmonious relations between so efficient an officer and his board. The circumstances that gave rise to the misunderstanding may be thus summarised from the report presented by Dr. Armstrong. In May last, during his temporary absence from home, a ship arrived with several small-pox cases on board. After inspection the patients were removed to hospital, and the ship disinfected. Some infected bedclothes, however, concealed in another part of the ship, were afterwards taken on shore by a healthy sailor, and were alleged to have caused three cases of small-pox in Jarrow. In the absence of their Medical Officer, the authority met and passed a vote of censure both upon him and his assistant; and although eventually they decided to let the matter drop they nevertheless did not rescind the adverse vote. Later on it was proposed that the Port Medical Officer should reside at the mouth of the river, a motion which would, if carried, practically dismiss Dr. Armstrong from the post. At that point the gentleman in question decided that the most dignified course would be to send in his resignation, which was accepted. There the matter stands. The incident furnishes strong proof of the necessity of some continuity and security of tenure on the part of Medical Officers of Health. A public board notoriously has no conscience, but it may be doubted whether a more signal instance of treachery and ingratitude has ever been laid before the public. In most cases of the kind the injured medical officer has not enjoyed the opportunity which chance has afforded Dr. Armstrong of making his wrongs known to the outside world. One other point to which attention may be drawn is the feeble attitude of the Local Government Board in the matter. As usual, the local officer has been left to fight his own battles alone and unaided. The traditions of the Department seem to insist that no active support shall be given to any medical officer, however just his cause, in the endeavour to defend his position against a hostile board.

Until the Public Sanitary Service can reckon upon the help of the Local Government Board in all just and progressive protests there can be little prospect of any solid advances in the local sanitary administration of this country.

THE ELECTION OF DIRECT REPRESENTATIVE FOR IRELAND.

THE counting of the votes by the Branch Council was completed on Saturday last, when it was ascertained that Mr. Thomson had been elected Direct Representative by a considerable majority. In him the profession in Dublin, the Conjoint Colleges, the Royal University, and the Queen's Colleges have secured a representative to whom the most captious critic could not offer objection. As the Vice-President of the College of Surgeons and a Senator of the Royal University, Mr. Thomson brings to his new office the dignity appropriate to so honourable a position. Intellectually, and by his long experience of teaching and examining, and public professional work in general, he ought to take his position as one of the most useful and capable members of the Medical Council in educational matters. Mr. Thomson is, also, a man of decided individuality, and unmistakably vertebrate; he is a lucid and deliberate speaker and a skilled writer, and, on the whole, it must be said that the Irish colleges and schools could not have sent forward a better representative.

The contest has been a most interesting one, and the upshot of it teaches many useful lessons. The first is taught by the record of the number of voting papers issued—2,768—and the relative number of papers returned—2,078. It thus appears that 690 voters did not take sufficient interest in the matter to induce them to attach their names to the voting paper and put it into the post (for the stamp was already attached). Considering that five candidates have, for the last three months, exhausted their energies in canvassing the constituency with addresses, circulars, post-cards, telegrams, and personal letters of importunity, the existence of such a cataleptic condition in one-fourth of the voters is amazing. If the rank and file of the profession in Ireland slumber in this condition of lethargy about their other public affairs, it will be readily understood why they occupy the humiliating public position which they do. At the election of 1886 the same phenomenon was seen, out of 2,671 voters only 2,040 returned their papers. The number of missing votes would have been much greater at the present election, but for an agreement formally entered into by the candidates that they would not raise any questions as to the validity of papers upon which irregularities (such as the inaccurate statement of qualifications) might appear. Such irregularities invalidated, at the 1886 election, 160 votes; at this election only three.

The final result of the poll was declared as follows:—

Thomson	866
Cuming	757
Jacob	455

Total 2,078

In analysing these figures it should be recollected that, in addition to the candidates named, there were originally two others, Drs. MacDonnell and Greene, who declared themselves the champions of the provincial practitioners and the antagonists of metropolitanism. Dr. Cuming, though strictly a metropolitan, posed also as the representative of provincialism because he happened to live in Belfast. After a time it became manifest that, with three so-called provincialists in the field all must inevitably lose, and some gentleman in the South of Ireland undertook to reduce the number by eliminating two of the three, for which purpose they proposed a preliminary vote as between them. Their enterprise did not succeed very well, for out of the 2,700 voters in Ireland they elicited answers from only 685, but the reply sufficed to show that Dr. Cuming, with his Queen's College backing, had the best chance of success. Wherefore, Drs. MacDonnell and Greene retired, and their voters, to the number probably of about 500, were ostensibly set free, and for them a general scramble ensued amongst the three remaining candidates. It was assumed that the great majority of these, being freed from their original promises, would exercise an unpledged vote, but it would appear from the result that the large majority of them felt themselves bound to vote for Dr. Cuming, as a sort of provincialist, and they did so with the result of running his probable poll up from 500 to 727, and proportionately running down to 455 the poll of Dr. Jacob, whose chief dependence was on the Poor-law vote. Mr. Thomson being sustained by his large metropolitan vote, and gaining some accession of strength from this unpledged contingent, beat all candidates out of the field.

The final lesson to be learned from the contest is that the provincial practitioners of Ireland are incapable of returning a Direct Representative, or, indeed, effecting any other substantial change in their own position, not because they are not strong enough, but because they are absolutely indifferent, and refuse to exercise their strength. We confess that we fail to see any force in the cry for a provincial Direct Representative, and it seems reasonable to suppose that association with the leaders of thought in a metropolis will be likely to produce a more experienced and competent representative than residence in the obscurity of a country town. Nevertheless, it seems that there is a substantial feeling in favour of the subject on the part of Irish provincials and we do not see why they should not gratify that sentiment if they have the power. But, if they have, and will not take the trouble to avail themselves of it they may, without pity, remain out in the cold. On this occasion, they have acted with complete want of sense. They were warned, and everyone knew, that without a unanimity, which never previously was experienced, they could not place their man and that the only effect of their running a provincialist would be to secure the coveted position for some one with a strong metropolitan and School-College backing, a consummation which they most dreaded.

One more aspect of this contest we must briefly allude to, and that is the wholesale abandonment of Dr. Jacob by the Poor-law men for whom he has spent a quarter of a century of his life. Mr. Thomson, Dr. Cuming, and every other person who aspires to medico-political life have, by this, learned, if they like to avail themselves of the instruction, that the less time, labour, and self-interest they expend upon the Poor-law Medical Officers of Ireland the better for themselves. Should they try to deserve the approval of this class in a public contest they will find, as Dr. Jacob has found, opponents started to keep them out of all positions of honour, and they will see many who ought to recollect past services quite willing to throw them over because they are asked to do so by some casual acquaintance.

Notes on Current Topics.

The Malarial Parasite.

MALARIAL affections are not comprised among the diseases with which the British practitioner has to deal in daily practice, but we have a sufficient number of colonies and dependencies in which they are rampant, to make the subject worthy of our serious attention. This was doubtless the reason why the subject was selected as one of the set discussions at the Royal Medical and Chirurgical Society, and the interest taken therein was testified to by the fact that this discussion extended over two full evenings, the second, indeed, of unprecedented length. We are fain to confess, however, that the moot points appear as far from settlement as before this prolix discussion. One's confidence in Laveran's parasite is somewhat disturbed by the telegram announcing Dr. Lawrie's disclaimer, and until the validity of its existence has been cleared up, it seems a trifle superfluous to go into details. Before it can safely be affirmed that particular varieties of the parasite are associated with particular forms of the disease, it would be well to make sure that any one such parasite has really been differentiated. As might be expected, a large number of the retired Indian Medical Officers inhabiting the Metropolis had something to say on the diagnosis and treatment of malarial disease, but they were, for the most part, unnecessarily reticent on the biological questions under consideration. What we want, in order to decide the questions at issue, is direct evidence, the outcome of personal observation and research. Instead of this, we were treated to copious quotations from the works of others, some of whom affirm one thing and some the other. Each speaker chose his supporters from among those whose views he had espoused, and we are left in a state of confusion not unusual when expert evidence is pitted against itself. It may be conceded that the problems are of exceeding and peculiar complexity, but this dialectic method of dealing with matters which are essentially of observation only tends to stultify original research and to confuse the points at issue. On the whole, assuming that there is a parasite of malaria, and that it has

been sufficiently identified, the balance of evidence seems to be in favour of all varieties of malaria being modifications of one and the same disease, the virulence of the affection in particular individuals and places being attributable to personal susceptibility or exceptionally favourable conditions for the development of the parasite.

Intra-Uterine Injections of Glycerine.

It is now upwards of three years since Dr. Pelzer, of Cologne, first called the attention of the medical profession to the intra-uterine injection of glycerine for the induction of labour and to stimulate uterine contractions. The publication of his paper on this subject with five illustrative cases in the *Centralblatt für Gynecologie*, was followed by the adoption of this alternative means of inducing labour by practitioners of an experimental turn of mind all over the world. The last number of the *St. Louis Medical Mirror* contains a critical review of the recorded cases in which this method has been tried, and the conclusions arrived at are sufficiently clear to merit notice. It seems that glycerine injections sometimes produce very violent uterine contractions, with the result of causing a high percentage of foetal mortality. This of itself is an obvious drawback to a method which was at the start hailed as a "simple, safe, and efficient means for the induction of labour and the stimulation of uterine contractions." Of 33 cases subsequently reported by Pelzer, 13 children were born dead or survived but a short time, and Pelzer himself admits that the injection of quantities varying from 50 to 100 cubic centimetres is likely to determine the death of the foetus. On the other hand, injections of less than 50 cc. are often ineffectual, and injections of glycerine, like other intra-uterine injections, are liable to be followed by shock, air-embolism, thrombosis, nephritis, and sepsis. Moreover, they sometimes give rise to glycerine poisoning, manifested by decomposition of the blood corpuscles, resulting in diseases of various organs, more especially nephritis, with hæmoglobinuria. Our contemporary concludes that the use of intra-uterine glycerine injections should be abandoned, or at any rate, that the doses should be reduced, special caution being indicated in the subjects of chronic kidney affections.

Bacteria in Agriculture.

In times gone by, as everyone knows, science has afforded a vast deal of help to the farmer. It may be questioned, however, whether the fields of scientific agriculture have been even yet fairly entered by scientific investigation. For many years past, the pressing problem has been how to obtain the nitrogen from the air (or elsewhere), and to convey it to the soil in such a way as to be available for the growth of plants. Bacteriologists have been at work lately, from this standpoint, in the investigation of the nitrifying organisms of the soil, and there now appears to be a good prospect of an immediate practical result from their labours. It has been announced in Berlin, before the German Agricultural Society, that Herr Notbe has succeeded in cultivating the special bacteria mentioned on a

large scale. He is convinced that the sowing of these cultures will make soils which need them more productive in a cheaper and more convenient way than the method of inoculating suitable earth invented some time ago. The expense of treating a Prussian *morgen*, about half an English acre, by the bacterial method, will be half-a-crown. If this plan prove to be of practical value, it will offer an undoubted boon to agriculturists. It is not a little interesting to note the extraordinary crop of discoveries and developments that are being daily opened up to the various arts of mankind by the comparatively youthful science of bacteriology.

Anti-Foreign Medical Movement in Paris.

SOME months since the strong anti-foreign feeling which has of late years grown up in Paris against foreign medical students and doctors was commented upon in these columns. That there has been no abatement in the crusade was shown by a recent resolution of the Montpellier students to the effect that the invasion of foreigners constituted an obstacle to their studies, and a threat for the future. Dr. Brouardel, Senior Member of the Medical Faculty, has lately made a public statement of his views upon the subject of the agitation. The chief cause he at once traced to the want of room in the schools and hospitals. The accommodation of the Paris medical schools he estimated as sufficient for 3,000, but, as a matter of fact, there were no less than 6,000 students, of whom 1,000 were foreigners. In order to lessen the pressure, the Minister of Public Instruction, last November, issued a decree prohibiting the further admission of strangers to the Paris Medical Faculty. That edict had the effect of driving the overflow of new-comers to the provincial medical faculties. At present, one doctor out of every five practising in France was an alien by birth. Dr. Brouardel suggested that the Minister of Public Instruction should create a new and special medical diploma, which would not confer the right to practise in France. To most Englishmen, this attempt to establish protection in intellectual matters will seem an extremely short-sighted policy. The coming London University could not fail to benefit greatly from the jealous exclusion of so many enterprising students.

A Milkman's Oversight.

THE intermittent or rather the remittent prosecution of fraudulent milk vendors forms a staple feature of police-court proceedings in most of our large towns. In no class of cases, probably, is there a greater assumption of injured innocence and a more copious fertility of excuse than among these humble but necessary tradesmen. A good example of both phases was produced last week before a metropolitan magistrate. The evidence showed that a Knightsbridge cowkeeper purveyed milk from which no less than three-fifths of the cream had been abstracted. In defence, the ingenuous milkman stated that he sold the milk as it was taken from his own cows. He was of opinion, however, that he had not stirred it up properly, so that some of the customers got the top layer, which con-

tained the cream, and unfortunately the inspector had been supplied with thin milk from the bottom of the can. This explanation did not satisfy the bench as to the three-fifths deficiency of cream, and defendant was fined 43s. There is a large field for local authorities in preserving the purity of this important article of popular consumption. To look after the milk is a simple, straightforward, and serviceable duty, more to be desired than prosecutions for the copping of peas and such-like debateable and transcendental proceedings.

The Notification of Diseases Act and its Adoption.

MR. CHAPLIN, in the House of Commons last week, quoted some interesting figures in regard to the adoption of the Notification of Diseases Act. The Act it appears is now in force, in districts containing an aggregate population of 27,220,000, out of a total population of 29,000,000. The question of making the Act of 1889 compulsory has been under the consideration of the Local Government Board, but the conclusion arrived at by the Board is that the Act is more likely to be enforced when it is voluntarily adopted by the local authority than if it were made applicable to a district without the concurrence of the local authority. Inquiry shows that at the end of last year there were 202 urban and 94 rural districts in which the Act is not yet in operation. The Board therefore intends to communicate with the local authorities in these districts with a view to bringing pressure to bear in order that the adoption of the Act should be carried out. Probably few of our readers could have had any knowledge of the remarkable progress which the Act has made throughout the country as a voluntary measure.

The Unpopularity of the Army Medical Service.

IF further evidence were wanted to show the unpopularity of the Army Medical Service, it is to be obtained from the results of the last competitive examination to fill the vacancies for the same; and in passing, we may remark that the War Office would do well to read, mark, and seriously reflect upon these results. Sixteen vacancies were declared, for which only seventeen candidates competed. But out of these seventeen, no more than nine were reported by the examiners to have obtained the requisite number of qualifying marks. The inference to be drawn from these facts is self-evident. Clearly, the Service has ceased to have any attraction for the bulk of the higher class of young practitioners who might otherwise be induced to compete. What the ending of this dearth of candidates will be can be easily foreseen. The War Office will ere long find themselves in a difficulty which, unless some steps be taken to remedy it, will only increase with time. As we have, however, repeatedly pointed out, the matter is one which does not rest alone with the War Office officials. It is one in which the British taxpayer is intimately concerned. The country pays for the Army, and has a right to demand that that Army for which it makes provision

shall be as efficient as possible. Included in that Army is the Medical Department; but if those in military authority, by petty jealousies, or puerile regulations, render the Medical Service unpopular to those who would otherwise join it, it is for the public to insist that all such internecine absurdities shall cease, and steps be taken to attract medical men to the Service whose competency would be a guarantee that the efficiency of the Department was being maintained. The dearth of officers and the number of unfilled vacancies is becoming a serious matter. We wonder that no member of the House of Commons has not already drawn attention to it. We should like to see the following suggestions incorporated into a question put to the Secretary of State for War:—"Having regard to the clear evidence which exists of the unpopularity of the Army Medical Service among young medical men, it is imperative that some public inquiry be made respecting the causes of that unpopularity, and that steps be taken immediately to remedy the existing unsatisfactory state of things."

Multiple Tumours of the Cerebrum.

A SPECIMEN of considerable interest was recently shown at a meeting of the New York Pathological Society. It was that of the brain of a little girl who had previously to her death suffered from some obscure nerve lesion. The history was that after a protracted attack of diarrhoea the child passed into a condition of dull consciousness, and finally became cataleptic. The only symptom present of cranial paralysis was the absence of pupillary reaction to light and accommodation, and the diagnosis arrived at was that of a tumour probably of the basal ganglia. There was no enlargement of the head, no optic neuritis, nor any sign to indicate distension of the ventricles. Finally the child died, apparently from inanition. At the post-mortem examination, on the basal surface of the left cerebellar lobe a small, whitish tumour was found, apparently connected only with the pia mater. It was also found that the head of the caudate nucleus on the right side was the seat of a similar new growth. A third new growth, and the one which had produced the symptoms, was found to involve the anterior and posterior quadrigeminal bodies. No mention is made in the report of the microscopical appearances of the growths, consequently their exact nature is a matter of speculation. A point worthy of special note is the absence of any marked clinical features indicative of the serious nature of the lesions which were present.

Syphilis from an Insurance Point of View.

THE question of syphilis in relation to life insurance is an important one, and it is doubtless the case that not a little divergence of opinion prevails upon the subject. The remarks, therefore, of Dr. MacLaren, in the March number of the *Edinburgh Medical Journal*, in this connection are opportune. The author classifies, for insurance purposes, all syphilitics under the three following groups:—1. If a man has been properly treated, the probabilities are, that provided he is of good constitution and habits, that no complications will arise, and

the expectation would be that he will go through life with scarcely more appreciable risk than one who has never had the disease. 2. If the proposer has not undergone a sufficient course of treatment, and applies for insurance before the expiration of six years, and yet is not suffering from any tertiary manifestations, and is otherwise satisfactory, the chances are that he may escape the malignant form, but a 10 per cent. extra should be charged until the expiration of the six years, and then his case should be reconsidered. 3. When tertiary symptoms have developed, the proposal should be absolutely declined, because, while treatment may temporarily remove these, it cannot eradicate the tendency to recurrence; and clinical observation has shown that those so affected rarely live beyond a term of ten years, and often much less when palliative treatment is wanting. In view of these pronounced statements, we should be glad to hear the opinions of other medical officers attached to insurance companies, and to learn to what extent their practice coincides with that which Dr. MacLaren adopts.

The Latest Experimental Researches with Electricity on Diphtheritic Bacilli.

HARDLY has the wonderful discovery of Professor Röntgen been made known and commenced to give satisfactory results, than another and perhaps still more important discovery is announced to the scientific world. Our French Correspondent informs us that M. S. Arsonval, Professor at the College de France, has just presented to the Académie des Sciences the results of his experiments on the action of electricity on microbes. Passing an electric current producing two-hundred and twenty-five thousand oscillations per second, through a glass tube containing the microbe of diphtheria, he found that, at the end of a very short time, the secretion of the microbes, which before the operation had been mortal, had completely lost their virulence. On the other hand, and this is the important point, the current had not completely destroyed the toxins, but had transformed them into vaccine. In this way, M. S. Arsonval was able to render immune from diphtheria about thirty guinea pigs, inoculating them with the liquid. According to the Professor, these electric currents contravert the organism without producing any morbid effect, that is to say, while currents producing only one-hundred and fifty thousand oscillations per second kill instantly, those of the velocity employed by M. S. Arsonval are absolutely harmless. Consequently it is possible to treat directly certain bacterial affections by this method, and experiments are being made in this direction on guinea pigs which are yielding very satisfactory results.

A DEPUTATION of the Medical Faculty of Würzburg University, of which Dr. Röntgen, the discoverer of the new photography, is a Professor, presented him last week with a diploma conferring on him the title of Doctor of Medicine, an honour granted unanimously by the Faculty.

Bicycle-Riding and Urethral Troubles.

"BICYCLE-RIDING," says an American surgeon, "with the common saddle, such as is sold with most machines, causes disease of the prostate and urethra, the severity of which is in proportion to the amount ridden and the relation of the buttocks and perineum of the rider to the saddle." The subject is one, the author states, to which he has paid a large amount of attention, having been led to do so by the number of patients presenting themselves with prostatic and urethral irritability, who denied a venereal history. The chief symptoms were frequency of micturition, with some dysuria, and endoscopic examination of the prostatic urethra showed a swollen, velvety, and a sensitive-to-pressure condition of the mucous membrane. In short there was present a parenchymatous prostatitis together with granular urethritis. The cause of these conditions was traced by the author to faulty-made saddles by which the whole weight of the patients' bodies were made to rest upon the perineum, instead of upon their buttocks. Hence, when the bicycle-riding was indulged in to excess the trouble resulting therefrom was not long in developing. In all cases the author interdicted the use of the bicycle, and then the symptoms quickly began to subside. Inasmuch as prostatitis is of very uncommon occurrence, save when caused by gonorrhoea, the point raised by the author is of some interest. There are reasons, however, for doubting whether, at all events in this country, medical men have been called upon to treat cases of prostatitis the origin of which could be distinctly traced to riding a bicycle. Manufacturers have paid so much detailed attention to perfecting the saddles of the machines that an ill-fitting saddle must now be almost a thing of the past. Nevertheless, it is well to bear in mind that harm of the kind to which the author draws attention has been observed.

How to Sterilise Cotton.

A RATHER ingenious plan for sterilising cotton is referred to in a French contemporary. A piece of cotton is taken, twisted on a stick or a piece of wood, and dipped into a saturated alcoholic solution of boracic acid for a moment or so. It is then withdrawn from the solution, and a light is applied to it, as the result of which the alcohol burns out, while the boracic acid prevents the cotton from burning. Five seconds are enough; as soon as the flame turns green it is extinguished. The cotton remains white, dry, warm, but absolutely sterilised.

A New Material for Skin-Grafting.

THE difficulty which is sometimes experienced in obtaining skin grafts to unite is apt to interfere to a considerable extent with the ultimate success of a case, and this despite every care and the method which may be adopted. It is, however, worthy of mention that an American surgeon, Dr. Z. J. Lusk, has suggested a new and original method of obtaining material for skin-grafting. Having recently to treat a man with an unusually extensive burn, the result of a fall into a vat of boiling brine, the plan suggested

itself of using some of the exfoliated epidermis from the vesicles. A piece one inch square was softened and sterilised in warm boric acid solution, and divided into twelve grafts. Seven of these grew rapidly. The process was continued, and at the end of six weeks the very large surface had become completely covered with soft, firm skin. The same process was successfully applied to the treatment of an old varicose ulcer, the skin being obtained by raising a blister on the patient. This method seems simple enough, and evidently promises to be useful in practice.

The Nauheim Treatment at Bath.

ANY enterprise which is destined to improve and add to the attractions of the English spas, so that English invalids may be prevailed upon to patronise them instead of going abroad, is worthy of commendation. We notice in this connection that the Nauheim treatment has been introduced into the Queen's Bath at Bath, and despite the fact that the appliances have only been in use for a few months, already a thousand baths have been administered. It may be mentioned that the Nauheim treatment, or "Thermalscoolbad," consists mainly in the use of a highly carbonised hot brine bath, by which sufferers from cardiac affections are greatly benefited. It is only just to say that for this new development in the application of the Bath waters the town is indebted to Mr. Alderman H. W. Freeman, Surgeon to the Royal United Hospital at Bath.

The Cardiff Quack Prosecution.

WE learn that the excellent "Stipendiary" who adjudicated in the case of "Dr." Bridgwater, M.D., U.S.A., has refused to grant a case for a higher court, on the ground that the questions involved were those of fact, and not of law. As a corollary to this remarkable judgment, it is stated that "Dr." Bridgwater, M.D., U.S.A., has threatened to take proceedings against the medical man who laid the information in the case, with a view to recovering damages in respect of the prosecution. What has the Medical Defence Union to say to this new development?

An Action for Libel against the British Medical Journal.

A CASE of unusual interest to medical men generally was tried at the Manchester Assizes on Saturday last. A medical practitioner residing in Blackpool is connected, but without payment on either side, with two hydropathic establishments in that town. His name appears on large plates at the entrances and on the tariff bills. These facts were submitted to the editor of our contemporary, the *British Medical Journal*, for comment and an expression of opinion with respect to the ethical aspect of the case. The view given was that the exhibition of the plates was wholly incompatible with the honour and dignity of the profession. This was the libel complained of. For the plaintiff, Drs. Renaud, Collins, and David Little gave evidence to the effect that no ethical rule had been broken. While for the defendant, Sir Dyce Duckworth—whose testimony was wholly discounted by his

admission that his name, the hospital with which he was connected, and his private address appeared in an Insurance prospectus widely circulated, and placed in numbers upon public counters—Dr. Ward Cousins and Dr. Bateman stated that Dr. Kinsbury had broken an unwritten law of the profession. The judge, in summing up, apparently regarded the statement of which complaint was made as one of fair comment. But the jury were asked to consider whether there had been misstatement and comment which was unfair. They arrived at the latter conclusion, and awarded the plaintiff £150 damages. In reviewing the evidence and the facts of the case, it appears to us that the matter resolved itself into one of whether complaint had or had not been made by the local practitioners against their *confrère*. The *British Medical Journal* said that the practitioners had complained, and this is borne out by the fact that the editor was asked to express his opinion on the case. But at the trial it was apparently impossible to obtain any evidence in support of this statement from the other practitioners in Blackpool, from which we are led to the conclusion that at the last moment they left the editor of our contemporary in the lurch.

A Sensational Case in Vienna.

SOME of our lay contemporaries have been exercising their minds with respect to a supposed wonderful operation performed in one of the Vienna hospitals. The report is to the effect that a young man, aged 19, suffered from some abdominal enlargement, for which it was deemed necessary to perform laparotomy. When the abdomen was opened, "the professor found between the spine and the intestines the undeveloped form of a child without a head." Such is the announcement of which so much has been made. The tumour was removed but the patient succumbed. It is, we suppose, scarcely necessary to observe further than to say that there is nothing remarkable about this case. The tumour, was so far as can be gathered from the reports, simply a dermoid cyst, the contents of which are always various.

RESIDENTS in Johannesburg are suffering from an epidemic of typhoid and dysentery of a most serious character. Dr. Vissor, the health officer, states that never in his experience has there been so much typhoid in the town as at the present moment. The hospital is overcrowded with zymotic cases, and 150 extra beds are wanted. The outbreak, it is alleged, is due to impure water, owing to the prolonged drought, and also to bad milk.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

DEATH OF A LUNACY COMMISSIONER.—The death of Dr. Robert Lawson, one of the Deputy-Commissioners in Lunacy, took place in Edinburgh last week. Dr. Lawson, about a year ago, obtained leave of absence from the Board on account of ill health, and his decease was caused by an

affection of the heart. A native of Kirriemuir, Dr. Lawson went to Edinburgh to study medicine, taking his degree of M.B., C.M., in 1871, and M.D., in 1888. In 1874, he was an assistant in West Riding Asylum, Yorkshire, and before his appointment as a Commissioner in 1878, he was superintendent of Wonford House, a registered asylum in Devonshire. During his long term of service with the Lunacy Board, Dr. Lawson had wide literary tastes, and was the author of numerous contributions to medical journals. He was a warm supporter of the system of boarding suitable patients in private dwellings.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—An address entitled "Historical Sketch of Gynæcology during the last 50 years" was delivered by the Hon. President, Sir John Williams, Bart., London, on Wednesday, to the Society, in the Faculty Hall, St. Vincent Street, Glasgow. A large number of the Fellows and Medical Practitioners of Glasgow and surrounding neighbourhood were present. The address was an admirable one, and was thoroughly appreciated by the audience, after which a complimentary dinner was given to the Hon. President, and during the toasts, old reminiscences were revived which made "the old men" feel young again. The chairman reminded the members that the guest (Sir John) had once been a student in the "old College" in the High Street, and on the banks of the classic Molenduiar, "*sic transit gloria mundi*."

THE FIFTH YEAR OF STUDY.—At a meeting of the Students' Representative Council held last week a considerable amount of important business was got through, amongst which the report of the delegates who represented Glasgow in the Inter-University Conference was considered. Thereat it was unanimously adopted that the Students' Representative Council should petition the General Medical Council so as to arrange that the fifth year of medical study should be exclusively devoted to clinical work. It is well known that the University Commissioner, in increasing the number of years of medical study, intended the additional year to be devoted to practical work. It appears, however, that their object is likely to be defeated in practice, unless effect is given to the reforms which the new ordinances were designed to accomplish.

EDINBURGH UNIVERSITY RECTORSHIP.—We understand that Lord Balfour of Burleigh, the Secretary of State for Scotland, will be the Unionist nominee for the Rectorship in the University of Edinburgh, and Mr. Haldane, M.P. for East Lothian, the Liberal candidate.

THE MORISON LECTURES, EDINBURGH.—Dr. Alexander Bruce has delivered the course of six lectures for which provision was made by the Morison bequest, taking as his subject the minute anatomy of the central nervous system. The lectures were lavishly illustrated by lime-light views, and proved a source of instruction and enjoyment to the large audiences attracted by the lecturer's well-known acquaintance with this difficult subject.

EDINBURGH ROYAL INFIRMARY.—At a meeting of the Medical and Surgical Staff of the Edinburgh Royal Infirmary, held last week, it was unanimously agreed to hold two statutory meetings during the year to discuss any point arising which might affect the staff of the hospital. The meetings are to be held early in May and November.

THE LATE DR. ANDERSON, OF DUNDEE.—We are sorry to have to report the death of Dr. A. M. Anderson, who held the post of Medical Officer of Health for Dundee from 1882 until last year, when he resigned owing to failing health. Dr. Anderson graduated in Glasgow in 1864, and became a Licentiate of the Royal College of Surgeons, Edinburgh, in the same year. During the course of a busy life he filled the posts, in addition to the one noted above, of Superintendent of the Fever House in the Town's Hospital, Glasgow, and Superintendent of the Royal Infirmary and King's Cross Fever Hospital, Dundee. A few years ago he published some remarkably successful results obtained in the treatment of typhoid fever by means of large doses of salol.

It is understood that the Government of New Zealand will introduce a measure for the exclusion of consumptive persons on the same lines as that dealing with small-pox, making masters of ships liable.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

THE DEPOSITION OF PHARMACOLOGY BY THE LONDON CONJOINT BOARD.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is difficult to understand the object of the Conjoint Board in removing pharmacology from their schedule. The subject has for many years occupied a definite position in the medical curriculum, and has served a purpose which no other department can fulfil. It has shown the student of chemistry and physiology how he may utilise the scientific knowledge he has already obtained in the treatment of disease, and has laid a firm foundation on which his subsequent study of therapeutics may rest. Without it treatment can only develop into empiricism, and the science of medicine again degrade to an art.

But it is easy to find reasons why pharmacology should be retained, the difficulty lies in finding reasons why it should be removed. If the promoters of the abolition scheme wish to benefit medical students (as they would have us believe) why do they not turn their attention to the subject of pharmacy, which contains much that is useless to the practitioner, and is sadly in need of reform? Why, for example, should a medical student be expected to distinguish between the different kinds of aloes or senna leaves, or between the ordinary and granulated sulphate of iron? Would it not be sufficient if he were able to distinguish the active poisons of the *matéria medica* without having to struggle through the differential characteristics of comparatively innocuous roots and woods?

There are many ways in which the burdens of students might be lightened, but one is not by the abolition of a subject which helps to a rational understanding of the methods of healing and helps to diminish all future study in the field of medicine. If the Board persist in this folly it must sooner or later bring its own reward. The Universities, recognising the value of pharmacology, are raising the standard of requirements in this subject, and it is very improbable that they will follow the lead of the Conjoint Board in abolishing it. The result will be a further widening of the gap between graduates and diplomates, which will assuredly not be to the credit of the latter.

I am, Sir, yours, &c.,
C. R. MARSHALL.

Pharmacological Laboratory,
Downing College, Cambridge.

CONTRIBUTING CAUSES TO THE RECENT ARMY MEDICAL EXAMINATION FAILURES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The recently published Results of the Army Medical Examination certainly call for some inquiry. To what cause is the failure to fill the vacancies to be attributed? Different persons will assign different reasons. But if the candidates may be consulted on the subject, the real state of affairs should become more apparent. The fact is, that the candidates and younger members of the medical profession, rightly or wrongly, still consider the Army, with its many acknowledged drawbacks, to be a fair opening with which to commence their medical career, and would gladly enter it, if they only got a fair chance at the examination.

No candidate can now enter the Army Medical Department unless he fulfil the following regulations, viz., "that no candidate shall be considered eligible for the Medical Staff who shall not have obtained at least 'one-third' of the marks obtainable in each of the compulsory subjects, and at least 'one-half' of the aggregate marks for all the compulsory subjects." This regulation came into force only for the first time during the last two examinations, and resulted on both occasions in the vacancies being unfilled. If the first part of the regulation were only put in force, there would be now remaining no vacancies as well as no grievances. Several of the men disqualified by the second and newer part of the rule

would be eligible in accordance with the first and older part, and in many cases would have from four to six hundred marks to spare. It may seem an easy and rational condition of the regulation that the successful candidate be required to obtain half the aggregate of marks, but the candidate who has tried finds it very different. He is in a position to know by comparison that the Army Medical Examiners, as a combination, are the worst set of markers to be probably found. He also considers each Examiner marks you according, or in proportion to, his own knowledge of that one subject, of which alone he himself has made a special study of for perhaps more than a quarter of a century, entirely forgetting that the candidate has to reserve some of his already overtaxed memory for every subject and its different branches required by the Medical Council since the first day he became a student, and now, again, required *en masse* for the Army Medical Examination. The second part of the regulation is simply unique in its application. Take the case of a candidate who has fulfilled the first condition of the regulation quoted above, that is, he has obtained 30 per cent. or considerably more, as happened in the recent examination in each subject. It will, however, be found that unless his excess of the required 30 per cent. standard reaches 50 per cent. he will fall short of half the aggregate or two thousand marks, if he cannot save himself by an extraordinary knowledge of some one particular subject, e.g., if a candidate at any time of his life made a special study of chemistry, so much that, by his knowledge he secured full marks at the Army Examination, he could owing to these marks afford only to get 30 per cent. in two such important subjects as surgery and medicine, as the extra marks in chemistry would bring him up in the other subjects to the two thousand marks and thereby secure a place for him. Now contrast this case with the candidate who has not made a special study of chemistry or any one particular subject; but who obtains from 40 to 45 per cent. in each subject, but as this percentage in the aggregate will fall short of the two thousand marks he will miss a place, though he may have actually, in each of the three out of the four compulsory groups, beaten by 10 or 15 per cent. the candidate with the extra knowledge of chemistry. Still he will remain unplaced, notwithstanding that he is as much as 15 per cent. in excess of the standard required in each of all the subjects; but it is here the injustice of the second part of the regulation makes itself felt again. This is the exact position of many of the candidates who were in for the recent examination, having got 10 or 15 per cent. more than the standard required in each subject, failed to get a place from the insufficiency of the aggregate of their marks, in most part due to the customary low marking of several of the examiners. Again, if at the present day a candidate is considered not eligible for the Army Medical Department unless he obtains 2,000 marks, it may accordingly be inferred that at least nine-tenths of the present Army Medical Staff are not eligible for the same reason that they never obtained anything like 2,000 marks when appointed. Quite previously to the enforcement of the present regulation, men received commissions with 1,200 marks, or thereabouts, and there are to-day men considered not eligible with 1,500 to 1,800 marks, and in this way, vacancies remain unfilled. It is to be hoped that it is not yet too late to abandon such an absurd regulation, which, in the hands of low-marking examiners, will eventually render the Army Medical Department needless. There is a strong feeling amongst the candidates that they will yet be called in, and there are instances in the past where men were called to fill extra places which were not even advertised at the time of the examination. The candidates also expect the medical press will accord its support in redressing their grievances. To many of the candidates, as in the case of the subscribed, it means their last chance.

Thanking you in anticipation,

I am, Sir, yours truly,

TWICE REJECTED.

PSEUDO-COXALGIA.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I was very much interested in the report of Prof. Duplay's lecture on Pseudo-coxalgia, MEDICAL PRESS & CIRCULAR, January 15th, as I had two cases under

my care which slightly resemble the case of the woman, *st.* 43, which he quotes. If you would kindly give me space, I will very briefly give the principal points of the cases.

Both were males, *st.* 36 and 28 respectively. Their history up to a certain point is similar, and is as follows:—They noticed a hard, pointed swelling, about the size of a bean, in the inguinal region, just below Poupart's ligament and to the inside of the inguinal vessels, much resembling an enlarged gland. It was not painful, but gave a certain degree of stiffness when walking. No gonorrhoea existed at the time, but some years previously both suffered from that disease. The swelling increased in size slowly, and became more painful, with increased lameness. At its height the swelling was about the size of a large egg, half of it being above Poupart's ligament and half being below. At this time deep-seated fluctuation appeared—both were opened, drained, and syringed out with a solution of carbolic acid. The swelling almost disappeared, but when the cavity was allowed to close the symptoms returned. So far both were similar—a slight difference in their history takes place now.

The man, *st.* 36, suddenly and without cause got a most severe attack of sciatica extending to and most severe at knee. He lay in bed with thigh flexed on abdomen and leg on thigh, the thigh being rotated inwards. After ordinary counter-irritant treatment he was relieved of the pain, so that he could be removed to hospital. In hospital he was kept at rest in bed without any splint or support, and was put on iodide of potash and mercury internally for four weeks. Then he got about on crutches for some weeks, when he ultimately recovered with a slight halt and a turning in of his toes.

My other patient developed symptoms of sciatica more slowly. When I discovered the least symptom of it I got him to bed at once. He complained of great pain and tenderness at back of hip over sciatic nerve, but was never troubled with pain in his knee. I put him up in a weight and pulley extension apparatus, beginning with one and a half pounds, and gradually increasing it in ten days to nine pounds. He was a month in bed altogether. Then I got him up with a patten on sound leg and crutches, sent him to the seaside, where he recovered perfect use of the leg without any lameness or pointing in of toes. Twelve months afterwards the swelling and abscess returned, in this case in the same spot. It was opened under chloroform, and found to be at least three inches deep. He got better quickly.

The reason I give this very brief sketch of the cases is, that they are so rarely seen in country practice.

I am, Sir, yours, &c.,
M. L.

P.S.—I enclose my card, but not for publication.

MEDICAL TITLES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dr. Campbell Black deserves thanks for bringing this question to the front and keeping it there. No one who has studied the case of the medical profession and recognised the causes which retard its progress can dissent from Dr. Black's implied proposition that it is of far greater importance to put an end to false pretence and quackery within, than to overthrow quackery outside our ranks. Outside quackery, including the sale of quack medicines, does no harm to the legitimate practitioner; on the contrary, it manufactures invalids and aggravates disease; and as the vast majority of cases thus created or made worse gravitate in the end into the hands of qualified men, quackery from a sordid point of view, is an advantage to the whole profession. The only way effectually to hamper the unqualified quack would be by forbidding the practice of medicine in any department for gain to all save the legally qualified. That such a measure would put a stop to the infliction of a vast amount of misery needs no proof—proof is to be found in the frequent published reports, in which are exposed the cynical villainy with which the army of medical impostors, including cancer, rupture and consumption curers, pursue their aims. A measure hampering the sham-medical harpy would save from maltreatment and plunder a class of the community

—the weak and suffering—whose claim to the protection of the State is surely paramount; but he would be a very sanguine individual who imagined such a measure were within the scope of present day practical politics.

Meanwhile, the Medical Acts need amending to render them operative even to the meagre extent which their sense expresses. Dr. Bateman evidently was far too confident in his belief in the efficiency of the Acts, as the recent magisterial decision in the Cardiff case sufficiently shows. If that case be argued in the High Court it is probable the magistrate's judgment will be upheld. In the case of Ferdinand an appeal after magisterial conviction was heard by a bench of magistrates and the conviction was confirmed. Had the magistrates refused to convict, and had the case been sent for argument before the bench of judges, a very different result might have been looked for. Meanwhile, in the uncertainty of the law and in the absence of any public functionary charged with its enforcement, the unqualified quack flourishes apace and is enabled to amass wealth in proportion as he possesses capital to puff himself. This varies, and in proportion as he is pervaded by an anti-human indifference to the suffering and misery which he deliberately inflicts upon his victims.

I am, Sir, yours, &c.,

S.

Feb. 28th, 1896.

Medical News.

Royal Free Hospital, London.

At the sixty-eighth annual Court of Governors, held on Wednesday last, under the presidency of the Hon. Mr. Justice Bruce, chairman of the committee, the report of the past year which was read by the secretary, Mr. Conrad W. Thies, showed that the total cost of the new buildings which were opened by the Prince and Princess of Wales in July last, and other necessary alterations and improvements, had been about £29,300, towards which, the sum of £27,600 had been raised, leaving a deficit of about £1,700. The Chairman appealed to the public to help the Committee by providing the sum needed to pay off the remaining liabilities. The Medical Report showed that the number of patients treated during the past year was 35,714, as compared with 30,337 in the preceding year. Lord Rowton and Sir James Stansfeld were elected vice-presidents of the Hospital. At the conclusion of the meeting, Mr. Justice Bruce unveiled a marble memorial of the late Mr. George Moore, in the Moore Ward. He mentioned that Mr. Moore had been chairman of the Committee of the Hospital, and for many years devoted much time and energy to the welfare of the institution. He raised a large sum of money to purchase the freehold, and owing to his efforts the financial position of the Charity had been permanently improved. They, therefore, felt greatly indebted to him, and desired that his name should be remembered. The memorial was a replica of a similar tablet executed by Mr. John Adams Acton for Carlisle Cathedral. The cost had been defrayed by Mr. W. Parkin-Moore, of Whitehall, Cumberland. The following is the inscription on the memorial:—"George Moore, whose valuable services to the Royal Free Hospital are gratefully remembered, died November 21st, 1876."

The Cancer Hospital, Brompton.

At the forty-fifth annual meeting of the Governors of this charity, held on Wednesday last, Sir George Samuel Meason, J.P., in the chair, Mr. W. H. Hughes, the Secretary, read the report of the Committee, from which it appears that during the past year 2,233 new patients were received, 805 as in-patients, and 1,428 as out-patients, being in excess of any previous year since the hospital was founded in 1851. Considerable expense has recently been incurred in connection with the operating-room by fitting it up in accordance with the aseptic requirements of the present day, and providing anæsthetic and sterilising rooms, &c. The hospital has also been fitted throughout with the electric light, and the Committee make an appeal for continued support to enable them to pay for these necessary outlays, and to carry on the important work of alleviating, and, as far as possible, arresting the growth of this terrible disease.

Notices to Correspondents, Short Letters, &c.

✂ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

SEQUAH'S NEW ROLE.

THE representative and proprietor of the once prosperous quack nostrum "Prætie Flower" can now be seen, we are told, at the valety Music Hall, Birmingham, extracting molars "with his ac-ac-tomed dexterity." Having now got to tooth-drawing as a music hall attraction, perhaps some "M.D., U.S.A." will treat the public to the sight of a few surgical operations as a further progressive development of stage attraction.

MR. R. B. ANDERSON.—It is quite beyond our province, and would be beyond our space, to attempt to publish communications addressed to the branches of the British Medical Association.

MR. H. VAYASSEUR will receive a private note when a decision has been arrived at.

PROF LIECH's communication is unavoidably crowded out at press. It shall appear in our next.

DR. F. W. KIDD.—Your paper is held over for the production of the necessary illustration.

A NEW VERSION.

LITTLE BOY: "Please, want the doctor to come and see mother." Doctor's Servant: "The doctor's out; where do you come from?" Little Boy: "What! don't you know me? Why, we deal with you. We had a baby from here last week."

M.R.C.S., L.R.C.P. (Wolverhampton).—One method which has proved very effectual in the resuscitation of the new born is to dilate the infant's rectum with the finger. Coincident with the passage of the finger through the sphincter respiration will be started.

M.B.CANTAB. (Cheltenham).—There is no evidence at present to show that the serum treatment of cancer is of any use.

Meetings of the Societies

WEDNESDAY, MARCH 4TH.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (Limmer's Hotel, Conduit Street, W.).—8 p.m., Dr. H. McClure (Cromer): Some Factors in our Atmospheric Environment and their Relation to Health.—Dr. D. Kerr (Bath): Modern Improvements in British Balneological Practice.

OBSTETRICAL SOCIETY OF LONDON.—8 p.m. Specimens by Dr. Amund Routh, Dr. Galabin, and others. Adjourned Discussion of Mr. Harrison Cripp's paper on Abdominal Hysterectomy with Intra-peritoneal Treatment of the Stump, with Notes of Eight Cases.—Mr. Alban Doran: Cases of Fibroma of the Ovary and Ovarian Ligament removed by Operation, with a Series of After-histories of Cases reported in the "Transactions" since 1879.

SOCIETY OF ARTS.—8 p.m. Mr. A. A. C. Swinton: Roentgen's Photography of the Invisible.

THURSDAY, MARCH 5TH.

HARVEIAN SOCIETY (Stafford Rooms, Tithebourn Street, Edgware Road, W.).—8.30 p.m. Clinical Evening.

FRIDAY, MARCH 6TH.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—8.15 p.m. At Royal Kent Dispensary, Greenwich. Clinical Evening. Cases, specimens, &c., by the President (Mr. Ernest Clarke), Drs. Collic, Henry, Jocelyne, and others.

WEST-LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, W.).—8.30 p.m. Clinical Evening. Cases will be shown by Drs. Harrison, A. L. Scott, C. Chapman, and Sutherland, Messrs. Keasley, Edwards, and Bidwell.

SATURDAY, MARCH 7TH.

MEDICAL SOCIETY OF LONDON.—7 p.m.—Anniversary Dinner at the Whitehall Rooms, Hôtel Metropole.

WEDNESDAY, MARCH 11TH.

LARYNGOLOGICAL SOCIETY OF LONDON (20 Hanover Square, W.).—5 p.m.—Adjourned Discussion of "Foreign Bodies in the Upper Air and Food Passages," introduced by Mr. Charters Symonds at the February meeting. Members who intend taking part in the Discussion are requested to communicate at once with the Honorary Secretaries. The following cases and specimens will be shown:—Dr. Clifford Beale:—Cyst between Tongue and Epiglottis; Case of (?) Cancer or Tubercle. Dr. Bond: Maggots in the Nose (case and specimen); Myxoma of Vocal Cord (case and specimen). Mr. E. C. Stabb: Lupus of Palate and Larynx; Tumour of Soft Palate. Dr. St. Clair Thomson: Myxoma of Vocal Cord (case and microscopic section).

THURSDAY, MARCH 12TH.

BRITISH GYNÆCOLOGICAL SOCIETY (20 Hanover Square, W.).—Specimens.—Dr. Purcell: Three Uteri removed per vaginam for Malignant Disease. Dr. Schaacht: Uninterrupted Tubal Gestation containing Fœtus. A Discussion on "Ventriculo-fixation, ventro-suspension, and Allied Operations with their Results" will be introduced by Mr. Mayo Robson.

Vacancies.

Birmingham and Midland Eye Hospital.—Assistant House Surgeon. Salary £50 per annum, with apartments and board. Testimonials to the Chairman on or before March 12th.

Boscombe Hospital.—House Surgeon (unmarried). Salary £60 with board, lodging, and washing. Applications and testimonials to the Hon. Sec. on or before March 9th.

Bristol General Hospital.—House Surgeon.—Salary £120 per annum, with board, residence, &c. Applications to the secretary on or before March 18th.

Burton-on-Trent Infirmary.—House Surgeon. Salary £130 per annum, with a prospect of rooms in the Infirmary free; also coals and gas. Applications and testimonials to the Hon. Sec., Mr. J. Jones C. (Printing, The Infirmary, Burton-on-Trent, on or before March 12th.

Chelsea Hospital for Women, Fulham Road, S.W.—Resident Medical Officer. Salary £20 per annum, with board, lodging, and washing. Applications and testimonials to the Secretary on or before March 14th.

Cornwall County Lunatic Asylum, Bodmin.—Junior Assistant Medical Officer. Salary £100 a year, increasing £10 yearly to £120, with board, lodging, &c. Applications to the Medical Superintendent at the Asylum, on or before March 19th.

Greenwich Union Infirmary.—Second Assistant Medical Officer (unmarried). Salary £80 per annum, with board, lodging, washing &c. Applications and testimonials to the Clerk of the Guardians before March 18th.

Metropolitan Asylums Board.—Assistant Medical Officer (unmarried) for the North-Western Fever Hospital, Haverstock Hill, N.W. Salary £180 first year, £180 second year, and £200 subsequent years. (See advert.)

National Hospital for Consumption for Ireland.—Physician as Resident Medical Officer and Registrar. Salary £100 per annum, with apartments, &c. Applications and testimonials to the Hon. Sec. not later than March 14th. (See advert.)

Sunderland and North Durham Eye Infirmary.—House Surgeon. Salary £50 a year, rising to £90 after six months. Applications and testimonials to the Chairman of Committee, care of J. F. Potts, Secretary, 18 Derby Street, Sunderland

West Sussex Asylum.—Medical Superintendent. Salary £450 a year, with unfurnished house, light, washing, coals, &c. Applications and testimonials to the Clerk to the Committee on or before March 25th.

Appointments

GRIFFITHS, P. E., M.B., B.S. Lond., M.R.C.S., Honorary Surgeon to the Cardiff Infirmary.

HALL, J., M.B., Ch.B. Vict., M.R.C.S., L.R.C.P., Junior House Surgeon to the Salford Royal Hospital.

PAGE, F., M.D. Edin., M.R.C.S., an Examiner in Clinical Surgery in the University of Edinburgh.

RAY, J. H., M.B., Ch.B. Vict., M.R.C.S., L.R.C.P., House Surgeon to the Salford Royal Hospital.

RENSHAW, J. A. K., M.B., C.M., M.A. Cantab., L.S.A. Lond., House Surgeon to the Manchester Royal Infirmary.

STONHAM, C., F.R.C.S. &c., Surgeon to the Westminster Hospital.

TAYLOR, A. K., M.B., C.M. Edin., L.R.C.P., L.R.C.S. Ed., Honorary Assistant Physician to the Cardiff Infirmary.

TAYLOR, J., F.R.C.S. E., Honorary Consulting Surgeon to the Wrexham Hospital.

TAYLOR, W., M.D. Edin., L.R.C.P. Edin., M.R.C.S., Honorary Consulting Physician to the Cardiff Infirmary.

TURNER, W., M.B., F.R.C.S., L.R.C.P., one of the Visiting Surgeons to the Seamen's Hospital Royal Victoria and Albert Docks, (a Branch of the Seamen's Hospital) at Greenwich.

WATKINS, B. V., M.B., Ch.B. Vict., M.R.C.S., L.R.C.P. Lond., House Surgeon to the Manchester Royal Infirmary.

Births.

BOND.—Feb. 26th, at Leyton, Essex, the wife of Mayston Bond, M.R.C.S., L.R.C.P., of a daughter.

REVELL.—Feb. 27th, at 11 Granville Road, Southfields, Wandsworth, S.W., the wife of Hugh Stanley Revell, of a daughter.

ROES.—Feb. 28th, at 9 Pavilion Parade, Brighton, the wife of Douglas M. Ross, M.D., of a son.

SMYTH.—Feb. 24th, at Adelaide Road, Brockley, S.E., the wife of F. Sydney Smyth, F.R.C.S. Edin., of a daughter.

TAYLOR.—Feb. 25th, at Thrupton, near Andover, the wife of James Taylor, M.D., of a daughter.

Marriages.

WILLEY-PERRY.—Feb. 27th, at Christ Church, Sneyd Park, near Bristol, Frederick J. Ingor Willey, M.B., B.S., M.R.C.S., Crouch End, London, N., to Florence Elizabeth Perry, B.Sc. Lond., second daughter of Benj. Perry, Esq., Avonleigh, Stoke Bishop, near Bristol.

Deaths.

BUDD.—Feb. 26th, at Barnstable, Richard Budd, M.D., in his 87th year.

BYRNE.—Jan. 14th, at Hay, New South Wales, Dr. Edward H. Byrne, of heat apoplexy.

HALL.—Feb. 28th, at Ballisborough, William Hall, L.R.C.S.I., and L.R.C.P.L., son of John Hall, aged 28, deeply lamented.

ILOTT.—Feb. 21st, at Bechtfield, Bromley, Kent, James William Ilott, M.R.C.S., L.S.A., aged 80.

LAWSON.—Feb. 22nd, at Mayfield Terrace, Edinburgh, Robert Lawson, M.D. Edin., F.R.S.E., Deputy-Commissioner in Lunacy.

LYNCH.—Feb. 19th, at Sudbury, Suffolk, John Cox Lynch, surgeon, aged 60.

MOORE.—Feb. 28th, at Rockcorry, co. Monaghan, Robert Wm. Moore, B.A., M.B., T.C.D., only and dearly-beloved son of Dr. Robert E. Moore, Rockcorry.

NOTES ON A CASE OF SO-CALLED ELEPHAN- TIASIS. (a)

By FREDERIC WM. KIDD, B.A., M.D.,
Master of the Coombe Lying-in-Hospital, Dublin.

THE patient, æt. 33, sent to me by Dr. Blake, of Ravensdale—has never been abroad, nor is there any suspicion of a syphilitic origin—states that about thirteen years ago she got a fall, to which she attributed the growth of the tumour. The tumour commenced in and involved all the tissues of the right labium, and hung down more than half way to her knees. It did not grow quickly at first, but increased more rapidly for the last eighteen months. Patient had never sought advice, and only now came because the growth had assumed such proportions that it was impossible for her to sit down with any comfort. There were no disorders of menstruation or micturition. The operation for the removal of this growth was done on December 7th, 1895. Before operation an attempt was made to pass the catheter. This at first was unsuccessful, as the catheter went up its whole length into a kind of sinus or space, and the point of it could be felt anterior to the symphysis pubis and nearly on a level with its upper border. An elliptical incision having been made, the diseased tissues were dissected out from the anterior surface of the symphysis, where they were very adherent; bleeding points were ligatured or twisted, the site of the clitoris giving most trouble. A drainage-tube having been inserted the length of the wound, it was closed with numerous silkworm-gut sutures. One small nodule of this fibrous-like tissue was left immediately anterior to and above the meatus urinarius—owing to the patient becoming rather collapsed, with the intention of removing it by a subsequent operation if the growth showed any tendency to recur. The wound did not heal by first intention—a result probably due to the low vitality of the part and its œdematous condition. The tissues became very œdematous, and at one time had an erysipelatosus-looking blush. Some suppuration took place, and it was only by the most absolute care that septic trouble was avoided. There must have been many lymphatics in a condition likely to absorb septic matter. The temperature never went above 101.2°. She made a good recovery, though somewhat slow. The condition of the patient two months after the operation was not quite satisfactory; several small sinuses existed about the middle of the wound and when laid open and joined together it was found that the cavity into which they opened was just similar to the description given by Dr. McWeeney, where a smooth mucous membrane lined the so-called cavities of sinuses in the original tumour. The skin above the symphysis is hard and hypertrophied and could be easily removed, but the patient will not hear of another operation at present.

When removed, and in the recent condition, the

tumour weighed 5½ lbs. The following was the report made by Dr. McWeeney:—"The tumour is whitish in colour, covered close to the pedicle with rather dark-coloured skin, from which grew a few long hairs, whilst elsewhere it is covered with epithelium which has the character of mucous membrane. It is lobulated and very irregular in shape, with numerous papilla-like excrescences, so as to resemble a gigantic wart; the consistency is rather soft. Between the larger lobes are curious sinuous cavities, some of which are actual passages or canals running right through the mass from near the pedicle at one end to the free convexity on the other. Part of the skin covering the base of the tumour is covered with innumerable small pedunculated protuberances like fungiform papillæ. Microscopically, the tumour consists of a somewhat œdematous fibrous tissue of loose texture containing so many lymph clefts that in places one might almost term it a lymphangioma. There are also very numerous newly-formed blood-vessels. Around the lymph clefts are many collections of lymphoid and epithelioid cells. Sections of the papilla-like protuberances show essentially the same appearances. The surface is covered with stratified epithelium, which, from its slightly-developed horny layer and absence of hair follicles, may be said to constitute a mucous membrane. I should be inclined to class this specimen provisionally as *molluscum fibrosum*."

The points of interest in the case are the comparative rarity of this form of growth; the presence of these cavities or sinuses permeating it; the size it had attained before relief was sought; the absence of serious trouble, both from hæmorrhage during the operation and from septic absorption when portion of the wound suppurred; the question as to whether the growth would be one likely to recur if any portion of it were left behind.

It was usual to refer cases of this nature to repeated attacks of an erysipelatosus character, or to obstruction of the lymphatic channels, from the presence of the

(a) Read at the Obstetrical Section of the Royal Academy of Medicine, 31st January, 1896.

"*filaria sanguinis hominis*," but in this case there was no history of previous inflammatory attacks nor had the patient ever been abroad, which alone could account for the presence of "*filariæ*." In the accompanying illustration (from a photograph taken by Dr. Alfred J. Scott), the patient is on a gynecological chair, the thighs abducted and the knees supported on the crutches of the chair.

ON SOME CASES OF HERNIA.

A Post-Graduate Demonstration given at the West London Hospital, on November 6, 1895.

By W. McADAM ECCLES, M.S., Lond., F.R.C.S.,
Eng.,

Assistant-Surgeon, City of London Truss Society, and West London Hospital, &c.

I SHALL, first of all, show you a series of cases illustrating some points in connection with femoral hernia. This form of rupture is always one which has especial interest, but more particularly so when occurring in male subjects. Femoral hernia is rare before the age of puberty; and before 12 years of age, it occurs nearly as frequently in boys as in girls. After this age, however, the proportion becomes vastly greater in the female sex than in the male.

About eighteen months ago, a boy, æt. 9, was brought by his father to the Truss Society, with the complaint that he had had a swelling in the right groin for about a year. On examination, a well-marked, rounded protrusion, presenting all the typical characteristics of a femoral hernia was found. It was completely reducible, and seemed to give the little fellow but a small amount of trouble. There was no family history of rupture, though it is by no means uncommon to find in these cases of femoral protrusion that some near female relative is, or has been, also the subject of it.

The boy was fitted with an ordinary femoral truss. Great care is to be taken in dealing with these cases that the measurement taken for the truss is accurate, in order that it may be very nicely adjusted. If too short, the instrument will be so uncomfortable that the patient, especially if a child, will refuse to wear it; if too long, it is certain to press on the spine of the os pubis, and thus cause intolerable pain.

This boy then was sent away wearing a well-fitting truss, with instructions that it should be kept applied day and night.

I have not examined him since until now. The patient is undressed before you, and I would have you notice that the truss is by no means worn out, and still lies comfortably in position. We will remove it, and it is obvious to all that there is no visible protrusion in the right groin, not even when the boy stands up and coughs. The truss, therefore, has not only been sufficient in keeping the hernia reduced, but it has done more; it has considerably lessened the tendency to protrusion; it has, in other words, brought about a partial cure. If one were to cut down on the parts now, the sac, owing to the continuous pressure and the condensation of tissues around, would probably be found partly, if not wholly, obliterated.

May we then allow this patient to discard his truss after his wearing it for eighteen months? No, I am certain it would, to say the least, be unwise to do so, for I am sure that seeing a strong, healthy, young subject has developed a hernia, he has still a tendency to such, and if no support be given the protrusion is very likely to reappear, and this particularly so in the femoral variety.

This patient presents the condition so often found after the so-called "radical cure" of hernia, and I venture to assert that the truss pressure has wrought in

his case practically exactly what an operation would have done, namely, the nearly complete absence of any impulse on cough. Nevertheless, in either case he should be still wearing a truss for some time yet to come.

The next case I bring before you is also a boy (kindly shown to me by my colleague Mr. L. A. Bidwell) who has a double femoral hernia, but with this important distinction, that the protrusion on the left side is irreducible.

It is open to us to treat this boy in one of two ways; firstly, to provide him with a double femoral truss, having the pad concave or hollow on the left side, or secondly, to perform herniotomy and attempt a radical cure, subsequently ordering him to wear an ordinary light double femoral truss.

The hollow-pad truss will probably bring about reduction before very long, and that with a minimum of risk, whereas an operation would certainly also effect the return of the contents at once, but with a certain amount of risk. The patient remains in danger so long as neither of these plans are carried out.

The third case, which is now before you, is a male adult who demonstrates a very interesting disease in addition to his hernia. He is the subject of diffuse molluscum fibrosum which he has had as long as he can remember. His femoral protrusion is very distinct. As he stands before you and coughs you will observe the pronounced manner in which the abdominal contents descend into the hernial sac. If we place him in the horizontal position the swelling is not altogether spontaneously reducible, but very slight taxis causes it to disappear with the characteristic gurgle of gut. A resonant note on percussion, with the usual intestinal sounds on auscultation, conclusively prove the presence of bowel in the sac. The hernia is of such a size, that of a tangerine orange, and the force with which it is protruded is so strong that at first I was doubtful whether an ordinary femoral truss would retain it, but when we adjust this 33-inch one it holds it up most satisfactorily.

It is interesting to note that although nearly the whole surface of his body is studded with molluscum swellings, many of which are of quite recent development, he has not a single nodule over the area with which the spring and pad of the truss come in contact. Can the use of the truss for several years have prevented the occurrence of the molluscum formation?

We now pass on to our fourth and last case of femoral protrusion. He is an older man, being sixty-three years of age. He has had hernia in the right femoral region for no less than thirty-seven years, but it was sadly neglected when it first appeared, consequently he had now a large protrusion, which is, however, wholly reducible. If we observe this rupture closely as it protrudes it will be seen that it has a tendency to pass upwards in front of Poupart's ligament as femoral herniæ so commonly do, as well as passing somewhat downwards.

In order to efficiently keep the contents of the sac within the abdomen this patient must have a specially made truss.

Firstly, a femoral pad is necessary in order that the ring be covered, but this will not be sufficient to retain the hernia.

Observe what happens when we put an ordinary femoral truss on and get the patient to cough—the rupture slips down and protrudes above and below the pad chiefly passing out above it.

In order to overcome this upward passage, what is called an inguinal fulness is to be superadded to the femoral pad.

It will be observed that this addition has a strap which is to be fastened to a buckle placed just within the anterior superior spine of the left ilium. To further satisfactorily deal with the lower portion of

the protrusion the femoral pad itself is prolonged somewhat downwards, and attached to its inner border is a shaped piece of jean which passes round the thigh and is fixed on the outer side by means of straps and buckles. This is called a thigh belt, and serves to prevent the truss being displaced upwards, and with the inguinal fulness and the ordinary femoral pad will effectually control the rupture.

Our first case showed well the effect of a truss in causing considerable improvement of a femoral protrusion in a young subject. I should now like to show you a case in which a scrotal hernia has been in like manner practically cured by the adjustment of a properly constructed truss.

This young man of nineteen, came to the Truss Society two years ago with a fully developed, but completely reducible scrotal rupture, and he was fitted with a rat-tailed truss. The prolongation of the pad in these trusses should be made quite soft and flexible without any part of the metal of the pad projecting into them. He wore this steadily day and night till he came up again a week or so ago, and now if you examine him carefully I think you will agree with me that there is little or no impulse on cough.

This result occurs in hundreds of cases, and I claim that it is quite as good as many a case of radical cure by operation. He is, however, still in danger of a recurrence of the hernia, and therefore he now wears an ordinary inguinal truss.

I am convinced after some close observation that a large proportion of "radical cures" are in precisely similar condition to this patient, and ought to be treated like him with a light truss for at least two years or so after the operation.

The sixth case is a man who presents the double affection of a hydrocele with a complete inguinal hernia, both on the same side. These cases are common enough, but the diagnosis of them is not always a perfectly straightforward matter. This one shows very clearly some of the points to be relied on in coming to a decision as to the condition. There is a slight constriction between the hydrocele below and the hernia above. The impulse on cough in the upper part is expansile in nature, that in the lower half is merely one of a forward character. The hernia is reducible with the peculiar gurgle of intestine and the feeling of a solid body slipping away from the fingers. The hydrocele is irreducible. Fluctuation may be obtained over the hydrocele, and this fluid-containing sac is translucent. There is a resonant note over the hernial portion, there is dulness over the fluid part. Auscultation gives evidence of bowel above, but reveals nothing below.

The treatment of such a case is to carefully tap the hydrocele, and apply a truss to the hernia.

We have now in our seventh case a very interesting one. Here is a man who is the subject of a partially descended right testis, which lies in fact in the inguinal canal just within the external abdominal ring. You will observe that the right half of his scrotum is practically entirely undeveloped. Very frequently retention of the testicle is associated with escape of contents of the abdomen, and in some of these cases a curious variety of inguinal hernia is induced. I refer to what is termed the interstitial hernia.

As the man stands before you, you will see he has some fulness in the right inguinal region due in part no doubt to the retained testis. On asking him to cough you will observe the descent of the hernia, and the typical direction which it pursues. Instead of passing from the canal into the scrotum, it turns upwards on to the abdomen, mounting up, as it were, by dissecting the layers of the abdominal parietes.

In this ascension the sac and its contents lie in one of three positions:—

1. Between the partial peritoneum and the fascia transversalis.

2. Between the internal and external oblique muscles.

3. Between the aponeurosis of the external oblique muscle and the skin.

As to the cause of this peculiar variety of hernia, it has been thought that the extension of the sac upon the abdominal wall is due to repeated attempts at reduction, especially in funicular hernia, where the opening of the internal ring is small. A similar condition may, of course, be found in one of the varieties of reduction *en masse*. Again, if a truss is worn over the external ring alone, in other words, a truss which is manifestly too long, it has been considered likely that the sac within the canal may pass upwards, being prevented by the pressure on the external ring from descending into the scrotum. Against this theory it may be urged that interstitial herniæ are very rare, but a truss worn in the above-mentioned wrong position is unfortunately very common.

Lastly, it has been held that a partially descended testis blocks the external ring when it lies just within it, and so retards the formation of a complete hernia, and in some cases, prohibits its production altogether. But, on the other hand, many patients with a testis in the canal are not the subjects of interstitial hernia.

It is true, however, that the majority of cases of interstitial hernia in males have a but partially undescended testis. When the condition occurs in women, their smaller and tighter external ring may account in some measure for the abnormal course of the protrusion. It may in all these cases then be said that the sac enlarges in the direction of least resistance.

The treatment falls under two heads, either operative or mechanical. I think such cases of the not far advanced types of interstitial ruptures may be greatly benefited by operation, and I strongly advise, if there be an offending testicle, that it be either replaced within the abdomen, or, if ill-developed, removed at the same time as the sac is dealt with. If, on the other hand, a truss be applied, one with an interstitial plate will be necessary. This testis, if present in the canal, need not be thought of, as it will take care of itself.

Our last case of inguinal hernia is a very rare one, in fact so uncommon is it that this is the only typical case I have seen. He presents the condition known as a cruro-scrotal hernia. By this term is meant a rupture which, instead of having a sac passing into the scrotum, has, as it were, developed a sac which pushes down in front of it the tissues at the upper part of the fold between the thigh and the scrotum.

These cases are usually, if not always, associated with malposition of the testis on the same side. It would seem that this organ having escaped from the external abdominal ring, misses the way into the scrotum, and turns or is dragged by a process of the gubernaculum toward the perineum, but stops short on its way.

This arrest may afterwards have developed in connection with it a hernia such as we have here before us.

If you will notice, in this man the right half of his scrotum is undistended by either a testis or the hernia, but presents very clearly the corrugated condition of the skin of a normal scrotum. The hernial protrusion lies altogether external to the scrotum itself. The treatment of such cases is that of an ordinary scrotal hernia.

There are now remaining two cases of ventral hernia to be seen. One is a man who has a typical protrusion through the linea alba some two inches above the umbilicus. This is the common position, namely, between the navel and the ensiform appendix, for such herniæ.

They are frequently in their earlier stages merely a prolapse of subperitoneal fat through an opening in the fibrous tissue of the linea alba. The opening in this is commonly wider transversely than vertically.

Such small ruptures may be retained, especially

when the patient is thin, by a Salmon and Ody's umbilical truss. If they cause much pain, as they not infrequently do, I usually operate on them by a vertical incision on to the tumour, freeing the sac if there be one, or the tag of fat if this is all that is protruded, and then transfixing either and cutting the part away. The edges of the opening are now refreshed and sutured transversely with silk.

The last case I have to bring before you is a man with a well-marked non-traumatic protrusion through the linea semilunaris.

These are nearly always on the left side and below the umbilicus, this possibly being due to the fold of Douglas.

They occur usually after middle life, as in our patient, and by no means infrequently become strangulated when they contain bowel.

A small umbilical pattern truss answers well in the majority of these cases. Operative treatment is not very satisfactory in producing a radical cure.

CLINICAL NOTES OF GYNÆCOLOGICAL CASES FROM A PROVINCIAL HOSPITAL. (a)

By E. F. ELIOT, F.F.P. & S. Glags.,
Surgeon to the Women's Hospital, Southampton.

HAVING been to some extent instrumental in initiating the establishment of a hospital for the treatment of the special diseases of women in Southampton, I think a short account of its foundation and work may be of some little interest. I feel acutely how very difficult it is to introduce any new idea or any information of any real interest or importance, and my apology must be that, in bringing before your notice this evening some details of the early work of a small hospital, and recording a few notes of my earliest cases, I may be able to justify my own practice, and encourage renewed zeal and energy in some members of the profession, who, perchance, may be at the present time experiencing difficulties similar to my own, and also show the leaders and teachers of gynecology that their seed is not cast in vain, but that it is finding root in remote corners of the land.

After I had been in practice for some years in Southampton, a great many cases requiring special treatment came under my observation, cases which appeared to me to be outside the pale of ordinary medical and surgical treatment, and as there was no institution where such cases were treated, or treated in any special manner or department, a small committee was formed which, after consultation with Mr. Lawson Tait, decided it would endeavour to establish an institution where cases of a special nature could be dealt with. I need not refer to the uphill nature of the work, except to say we have had a hard struggle, but now, I am thankful to say, we are established, and I hope doing some useful work. I am quite satisfied that this work should be done at a special institution, as really there is no branch of surgery which requires more special knowledge, more special care and tact, and more special forethought and judgment in weighing the importance of the history of each case.

The female pelvis is, at any rate to a beginner, a most gloomy and dark region, wherein one must always be prepared for the unexpected; as it often happens that the surgeon launches on a voyage of discovery, and does not know what he may have to do or deal with until the patient is on the operating table, and the operation is commenced. Even my short experience has taught me that cases which before operation have promised to be of a simple and straightfor-

ward character are often cases of extreme difficulty, and tax the resources and skill of anyway the young operator, to the utmost.

There are such a large number of cases of women who eventually find their way to special hospitals and to the consulting-rooms of abdominal surgeons, who tell the same tale of woe, and who have been going from doctor to doctor to find relief, cases in which examination reveals nothing, or at the most, very little, and cases in which the greatest care and judgment are necessary in deciding on the right course to pursue. Advanced cases of pyosalpinx or myomata, or ovarian cyst are easy enough to recognise, but it is the chronic cases, the cases on the border-land, that require the knowledge gained only by experience and practice.

In hospital practice, when it comes to a question of operation, I always put the case to the patient and her friends under certain heads:—(1) the probable result of leaving the case alone; (2) the certain results of medical treatment; (3) the probable result of surgical interference and the exact methods proposed; (4) the risks of surgical operations. The choice must be made by the patient after considering these points. By this means no operation is forced on any patient, and each thoroughly understands, or has the chance of understanding, what is going to be done, and what object is hoped to be achieved. This is more important in a provincial town, as one has to live, perhaps, very near one's patient. In all these cases, a carefully recorded case, a carefully given opinion, and a carefully noted result place one in a position to answer any criticisms which may be passed in a decisive and unanswerable manner; and it is for this reason that we have been able to treat many attacks which have been made on our work with absolute contempt (and to leave them unanswered), knowing that our work rested on a sound basis.

All difficulties can be overcome by knowing they exist; being forewarned is being forearmed. By keeping a high standard of honour always before one, by building up a stock of experience, by having a sound reason for every measure one adopts, and by adopting a system of method in dealing with one's cases, all difficulties will soon disappear, or can be easily combated, and as a compensation for all the troubles and worries there is the greatest consolation in every difficulty that is overcome, and there is, so my experience teaches me, the hand of friendship and encouragement, and the word of counsel and advice, always waiting for the beginner amongst the veterans and leaders of our great profession.

Apart from the major cases and major operations, there is such a vast amount to be done in connection with uterine therapeutics, and to collect these cases together must build up an experience which must be of use to anyway the poorer inhabitants of a town, and, take it, this society welcomes an account of work done in the provinces, and that the leaders in London of this great branch of surgery are always glad to lay the little fragments of work done in a provincial town by a provincial man as a proof that their own work is not in vain, and that the doctrines they are teaching are finding root throughout the country.

In conclusion, I would draw your attention to the following cases, and thank you for the honour you have done me in listening to my paper to-night.

CASE No. 102.—Mrs. T—, *et.* 25, healthy till marriage four years ago; twins two years ago, and a year later a boy at the seventh month; regular, no dysmenorrhœa or discharge. Swelling first noticed six weeks ago, has increased rapidly since. Patient looks very ill and is losing flesh fast. When first seen tumour was up to umbilicus, slightly to the left side, and was diagnosed as a parovarian cyst (while the possibility of its being a cystic sarcoma or a collection of encysted fluid was entertained). No large glands or veins. Seen by Mr. Lawson Tait, of Birmingham, and he wrote: "A plain

(a) Read before the British Gynecological Society, Feb. 15th, 1896.

straightforward case of parovarian cyst, unless the pedicle be sessile, on which point you cannot be certain until you are there."

Operation, April 20th, 1895.—Median incision, tumour adherent in front and carefully peeled off; wall in places very thick; growth mostly omental, but it has spread over the whole peritoneal cavity; wall of gut very thin in places and riddled with miliary tubercle. Part of the omentum which had been adherent in front was removed. Abdomen flushed out and a drainage tube inserted. Patient rallied fairly well, and continued to do better than was expected. On April 25th (48 hours after operation) the discharge became distinctly fecal. On April 29th albumen appeared in the urine, and continued to do so. The fecal discharge steadily increased until on May 14th a large slough from the intestinal wall came away. Patient gradually emaciated more and more, and died quietly on May 27th (a month and three days after operation). The temperature was hectic throughout. The difficulty of diagnosis was the chief point of interest. There was no history of phthisis, and prior to her marriage she was a strong, stout, healthy girl. The rapid growth of the disease and the fact of it showing no signs, except wasting, until six weeks before operation, were the chief points which made one think of something more than a simple parovarian cyst.

CASE 59.—Mrs. C—, *set.* 36. Patient was a married woman who had had eight children and three miscarriages at early dates. Her youngest child was born three years ago. About two years ago she got gradually run down and weak. In June, 1895, she first noticed a swelling of the abdomen, and first had pain in July, 1895, and three weeks ago (Oct 30) first detected a definite lump. Catamenia regular and inclined to menorrhagia, lasting six, eight, or ten days. She had had pressure symptoms on rectum about three months, and on bladder about two months. She was a pale woman with an anxious expression, in awful pain and symptoms of obstruction. There was a tumour nearly up to the umbilicus, slightly to the left side, hard, irregular, and tender, and very slightly movable in all directions. No fluctuation or fluid thrill.

Per Vaginam, cervix looks upward and to the right. Uterus appears quite fixed and embedded in the mass felt from the abdomen. There is a large mass of a similar character to be felt in Douglas's pouch continuous with the rest. Myoma uteri diagnosed.

Operation, October 30th, 1895.—Median incision; a large mass of breaking down malignant tissue found adherent to abdominal wall. This was peeled off and found to be part of the omentum, which was extensively diseased, and which formed part of the tumour felt from about. After its removal the uterus, with one or two fibroids, was removed by the extra-peritoneal method, the whole of the broad ligaments being covered by the growth. After this the pelvis appeared quite clear, and was douched out, and then the remainder of the omentum tied off in sections; the subsequent mass weighed 4 lbs. Patient had no pain after the operation, nor subsequently, whereas it was previously described as unbearable. Her pulse kept steadily up to a hundred and over, but her temperature never exceeded 100°. A recurrence of the growth was felt on Nov. 9th in the epigastrium, and other nodules appeared later. Persistent diarrhoea, which could not be controlled, was her one bad symptom, except for gradually increasing weakness, from which she died at her home, on December 18th.

Microscopic Section.—The chief point of interest is the association of the two diseases—namely, cancer of omentum (the primary source being possibly the right ovary or tube, both of which were extremely diseased) and myoma of uterus.

CASE No. 36.—Mrs. W—, *set.* 31. Catamenia always regular and painless until six months after marriage, which took place five years ago. She then began to have abdominal and pelvic pain, which was intensified at the menstrual periods and was steadily on the increase. She had pains in the groins, thighs, and back, and was scarcely able to get about. Appendages enlarged and very tender.

Diagnosis.—Probably double pyosalpinx. After consultation with Mr. Tait, operation advised.

Operation.—The case turned out to be one of double hydrosalpinx. The left tube was removed whole, the right piecemeal. Case did well.

The chief interest is the fact of the hydrosalpinx being double. There was a history of gonorrhoea on the part of the husband.

CASE No. 19.—Mrs. M—, *set.* 36. This case was one of great interest, as it was not until after sections of the ovary had been cut that the true disease was discovered. The chief complaints were general ill-health, loss of flesh, and intolerable dysmenorrhoea. The appendages were enlarged and tender. Palliative treatment was tried for some months with eminently unsatisfactory results. She was seen by Mr. Lawson Tait, who regarded the case as one of chronic ovarian disease, and viewing the failure of medical treatment and the gradually increasing ill-health and weakness, suggested the removal of the appendages. This was decided on after explaining matters to the patient; and the operation was accordingly performed. Both tubes were irregularly knotty, and impervious to the finest bristle. The left ovary showed sarcomatous changes when examined by the microscope, though to naked eye appearance the ovary looked fairly normal, and it was very difficult to remove.

CASE No. 10.—Mrs. T—, *set.* 40. Patient had always had dysmenorrhoea and saw very little. Otherwise well till marriage in '73. Gonorrhoea soon after marriage. Has had one child. For the last seven or eight years has had several sharp attacks of pelvic pain, mostly on the right side, but of late, on both.

Per Vaginam.—Extensive pelvic peritonitis on both sides and a large tumour to right and back of uterus. During the last six weeks before operation several more sharp attacks of pain occurred.

Diagnosis.—Probably double pyosalpinx. The case turned out to be one of double pyosalpinx, associated with a suppurating ovarian cyst on right side. There was nothing to suggest that the cyst was a dermoid, but it is of interest that the cyst was bilocular, one cyst being full of serum and the other full of pus. Patient did excellently well, and wrote on Jan. 7th "I am going on splendidly." (There was nothing definite to show that the locule containing pus was in direct contact with the pyosalpinx, though this was probably the case.)

CASE H.—Mrs. R—, *set.* 45. History very obscure, "pain in womb," dysmenorrhoea, no definite menorrhagia, no pregnancy. Pain chiefly on left, shooting down leg, some pain also on right.

Per Vaginam.—Small fibroid in front wall of uterus. Great thickening and matting around appendages. It was decided to remove the appendages.

Operation.—Tubes very densely adherent, greatly thickened, and of almost cartilaginous hardness. Lumen quite impervious, no attempt made at radical operation on myoma.

This woman was told her operation was incomplete, as her tumour was left!! Tait present at operation. Patient seen a few days ago, quite well.

CASE K.—Mrs. W—, *set.* 39. Menorrhagia over five years, loss at times alarming and might almost be classified as flooding. Lasts eight to ten days, during which time she has to keep her bed, and is in very great pain. She had been under several doctors and had had a great deal of treatment. Myoma of the uterus was diagnosed and operation was advised, as this seemed the only proper way of treating the large myoma which was the cause of trouble in May, 1895. After consultation with Mr. Lawson Tait, patient refused operation unless I would undertake only to remove the appendages, which course of treatment some one had told her, was only necessary. This I naturally declined to do as I felt sure it was impossible to do so. She continued to waste and become more and more anæmic, till she was in a very critical state, the lips and conjunctivæ being almost colourless. Patient at last consented to submit to whatever operation I thought best to perform, and the operation of extra-peritoneal hysterectomy was performed on Sept. 7th, 1895.

Risks of hæmorrhage were specially guarded against and an ounce of blood would probably cover the amount lost.

Patient did excellently. The clamp did not come away for three weeks, but the wound kept clean and healed well. Temperature once reached 101 (on second day) but afterwards was never beyond normal limits. Pulse was never over 100.

The patient went away from hospital regretting the

operation, and maintained that she only consented to the removal of the appendages.

CASE J.—Mrs. B—, *æt.* 26. When I first saw the patient she had just returned from London, where she had been attending for two years at one of the leading hospitals, and had been treated for retroflexion. Came suffering agonies, largely relieved by removing a Hodge pessary. Examined shortly after: Uterus enlarged somewhat and retroflexed, some endometritis to judge by the eversion of the lips of the os, and by the discharge coming from it. Large and exceedingly tender swelling to left of and behind uterus. Similar but less pronounced tumour to right.

Operation explained and consented to. Large double pyosalpinx, the larger about the size of a good-sized orange. Both were firmly fixed in the pelvis by adhesions. Patient made an excellent recovery.

CASE No 4.—Mrs. O'K—, *æt.* 21. A miserable, spare little woman, was suffering a great deal, and was emaciating. Had been under a lot of treatment, and came describing her life as a burden and misery. She had suffered much at the hands of treatment. Mr. Tait saw the case in consultation.

On examination of specimens, both ovaries were enlarged, and they were composed of a number of small, thinly-walled cysts. The fluid in all the small cysts was clear. The tubes were irregularly thickened and very adherent.

A typical case for operation; not treated except at a special hospital, and could not get relief in London because she was not told what was the matter.

CASE 32.—Miss C—, *æt.* 20, single. Very difficult to obtain any definite history, except the following:—Menstruated first at 18 years, regular at first. In January, 1892, began to see more, sometimes two or three times a month. Great pain and bearing down. Yellow intermenstrual discharge for a vague period. Pain much worse after she had the discharge. No bad pain prior to discharge.

Per Vaginam.—Large tumour, probably pyosalpinx on right side, enlarged tube on left, hymen ruptured.

Operation.—Removal of double pyosalpinx, both very large. No very great amount of adhesions considering the size of the two diseased tubes. Patient did very well, but has had rather marked climacteric symptoms of pain, bearing down, &c. Was seen towards the end of 1895 at St. Thomas's Hospital by Dr. Cullingworth, who explained to her that all her trouble was due to the climacteric.

She had been told she had still a lump left which had not been removed. She is now quite well.

Clinical Records.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA PARK.

Case of Dilated Heart with Mitral and Tricuspid Murmurs much relieved by Treatment.

Under the care of DR. THOROWGOOD.

Resident Medical Officer, DR. CHAPPEL.

Mrs. A. C., *æt.* 37, admitted into Victoria Park Hospital, under Dr. Thorowgood, Nov. 26th, 1895.

Ten years ago patient had rheumatic fever, and some years previously suffered from chorea. She has been much worse in her breathing since a fall downstairs twelve months ago. On admission, she is livid in face, her cough is incessant with no expectoration, voice almost nil, sweats much, and has considerable oedema of legs and arms, abdomen swelled and contains fluid. Liver dulness extends two inches below ribs. Spleen normal Pulse 112, small. Urine, *sp. g.* 1024, contains albumen in small quantity. Dyspnoea extreme. Temperature normal. Tongue furred. Bowels open. Heart dulness extends from third to sixth rib and laterally from mid-sternum to axillary line.

At apex, præ systolic and systolic murmurs. Marked murmur at ensiform cartilage. Pulsation appears over whole anterior chest, and jugular vein pulse is very evident.

Some dulness with subcrepitant râle at both lung bases. She was ordered tincture of digitalis (πv) with acetate of potash and spirit of nitrous ether, and this suited her. Whisky 3 oz. in 24 hours.

Nov. 30th.—There being but little improvement she was ordered every evening a pill of

Pil. Hydrarg.

Ext. conil., *aa gr. ij*

The pill was taken with great advantage, and by degrees the cardiac dulness became less extensive as if the right heart was less engorged.

Dec. 10th.—Dr. Chappel prescribed for her:—

Tr. digit. πv;

Tr. Hucis vomice, πxv;

Sp. chlorof. πviij;

Doct. Scoparii, ʒj. M. T. d.

This suited well: she was soon up and about, and early in February was able to leave the hospital much improved in every way, and able to go up and down stairs without any marked distress. She gained 13 lbs. in weight in the hospital. Pulse, 100. Very little oedema of feet only. The systolic murmur was very loud at apex, followed by a ringing second sound. At ensiform cartilage also the murmur continued. The præ systolic murmur vanished after a few weeks in the hospital.

Remarks by DR. THOROWGOOD.—This case seemed to take a very favourable turn after a week of the pil. hydrargyri. This pill acted freely on the bowels, and under its influence the oedema rapidly diminished, while the cough ceased, and breathing became easy. The right heart was relieved and then the nux vomica tonic came in to strengthen the action of the heart with good effect. The amount of alcohol used in the case was very small. To start off at once in a case of this nature with alcoholic stimulants in large doses, and cardiac tonics, is a plan that seldom answers until the engorged heart has been relieved by pil. hydrargyri and digitalis, and sometimes by a small venesection. A small amount of albumen in the urine is by no means a reason for withholding mercurial medicines, provided a free action of the bowels be maintained.

Transactions of Societies.

OBSTETRICAL SOCIETY OF LONDON.

MEETING HELD WEDNESDAY, MARCH 4TH.

The President, DR. CHAMPNEYS, in the Chair.

HYSTERECTOMY FOR CARCINOMA UTERI.

DR. A. ROUTH showed a specimen removed from a woman, *æt.* 56, who had ceased to menstruate six years previously. Although only the cervix uteri appeared to be diseased he decided to remove the uterus as a whole. He gouged away the cervical growth and then removed the uterus, and having done so he found on cutting it open that it too was diseased. This case showed that it was possible for disease of the body to escape recognition, and it showed moreover the danger to which patients were exposed if one adopted the practice advocated by Dr. Lewers and others of removing only the obvious cervical disease.

DERMOID CYST OF OVARY REMOVED DURING PREGNANCY.

DR. GALABIN showed a specimen removed at the fourth month of pregnancy which proved to be a dermoid cyst of the left ovary with the usual contents. The other ovary contained several cysts with similar contents. In the tumour of the left ovary was seen a well-marked *corpus luteum* of pregnancy. The patient made a good recovery without any threatenings of abortion or the metrotaxis which one usually gets after removal of both ovaries. He pointed out that the removal of an ovary containing a vesicle on the point of rupture produced apparently the same effect as if the vesicle had gone on to rupture, and on this assumption one could understand why, when there was no vesicle approaching rupture, there should be no metrotaxis.

CANCEROUS DEGENERATION OF URRINE FIBROID.

DR. GALABIN showed another specimen removed from a patient, *æt.* 42, who had had a large fibroid of the uterus

for many years, with menorrhagia, and, for three months, metrorrhagia. That was in October, 1894. He performed oöphorectomy, removing both ovaries and tubes. The tumour penetrated a good deal into the left broad ligament. For about six months she remained free from symptoms of any kind, and then the bleeding recommenced, but she did not apply for advice until a year had elapsed. By that time the hæmorrhage had become continuous, and the discharge was thought to be somewhat fetid. He dilated the cervix, but failed to detect any signs of cancer. Nevertheless, he thought it best to remove the mass, which was then seen to be undergoing malignant degeneration. This case, he said, was of interest as showing that it was possible to explore the uterus without finding that cancer was there although present.

CURIOUS CONGENITAL APPEARANCE IN A FŒTUS.

Dr. LEWERS showed a fetus delivered at term after craniotomy, the mother being a woman, æt. 36, with two living children, sent to him by Dr. Currie, of Finabury Park. It presented a large pendulous mass springing from the front of the neck which a colleague suggested was of the nature of a cystic hygroma.

The PRESIDENT pointed out that it was a very unusual appearance in the fetus, and on his suggestion it was referred to a committee for examination and report.

HYDRONEPHROSIS SIMULATING OVARIAN CYST.

Dr. TURNER showed a specimen from a case which appeared to him to be clearly one of unilocular ovarian cyst. By the vagina the tumour appeared somewhat high up, and this, he admitted, ought perhaps to have put him on his guard. He also made out the presence of a coil of intestine over the cyst which might also have inspired a doubt as to its nature. The patient had consulted him for a supposed injury to the hip, and it was, so to speak, quite accidentally that he discovered the tumour at all. There was nothing in her history to indicate the nature of the cyst, which had never given rise to pain or inconvenience. She was 53 years of age, and presented marked spinal curvature, with pulmonary lesions consequent on an attack of pneumonia many years ago. On opening the abdomen he at once saw that it was not an ovarian cyst, and on tracing its attachments upwards he discovered that it was a hydronephrosis. The distended colon stretched right across it in front, and the peritoneum covering the cyst was exceedingly vascular. He stripped this off and removed the cyst after ligature by enucleation. The operation was almost bloodless and the temperature at once fell to normal. The patient did well, and he was on the point of authorising her getting up when one day on attempting to pass water she suddenly became faint and expired in three or four minutes. He mentioned that the cyst contained four pints of clear urine of normal specific gravity and free from albumen. The ureter was not blocked, but was bifid up to the pelvis of the kidney. He suggested that the condition was probably consequent on floating kidney, and that the ureter had somehow got obstructed, though there was nothing in the history to point to such an occurrence. The appearances post-mortem were absolutely satisfactory as far as the operation was concerned, and he was still at a loss to explain the real cause of the syncope, there being nothing in the heart or brain to account for it. The right kidney was large, and its ureter was also bifid. After the operation the quantity of urine had increased from 15 ozs. within a few days to 44 ozs. in the 24 hours.

Dr. HEYWOOD SMITH mentioned the case of a married woman, who presented an abdominal tumour extending equally on both sides of the pelvis. There were no symptoms to enable one to say for certain whether it was ovarian or renal, so he aspirated and withdrew only six ounces of urine, though the cavity contained several pints. The patient died the same day. *Post-mortem*.—An enormous hydronephrosis was found with calculi impacted in the pelvis of both kidneys.

ADJOURNED DISCUSSION ON DR. CRIPP'S PAPER ON ABDOMINAL HYSTERECTOMY WITH INTRA-PERITONEAL TREATMENT OF THE STUMP.

Dr. CULLINGWORTH said the author's paper reflected the change at present taking place in the attitude of the profession in respect of operations for myoma of the uterus. These, he thought, are certainly becoming more frequent,

partly because of the diminished mortality resulting from improved technique. With the lessened risk, he urged, it was justifiable to recommend operative interference in cases in which formerly they would not have ventured. These tumours were now recognised to be a source of much later misery and of menace to health and even to life. Patients could not be promised a cessation of their troubles at the menopause, for experience had shown that they might lead to various troublesome and even fatal diseases. One, therefore, no longer awaited the advent of dangerous complications before advising operation. Among indications for operative interference not mentioned in the author's list, he suggested: (1) when it becomes evident that degenerative cystic or other changes are taking place; (2) when the rate of growth has suddenly begun to increase; and (3) when, after the menopause, the tumours continue to increase in size. He agreed that the so-called intra-peritoneal method was preferable to the extra-peritoneal, the latter being a clumsy and unscientific procedure. It was necessary, however, to discover a means of securing the patient against the risks of hæmorrhage from the stump, but until it was suggested to tie the uterine arteries as a preliminary step, the extra-peritoneal method could not be supplanted. That method had now practically been superseded. The rivalry at present was not between the intra- and extra-peritoneal methods, but between the method of leaving the cervix and that of removing the entire uterus. Recently the propriety of removing the tumour through the vagina, with *morcelement* if necessary, had come to the front. He had performed abdominal hysterectomy in 40 cases, in 9 by the extra-peritoneal, and in 31 by the intra-peritoneal method, the cervix being left in all the cases. Since he first resorted to the intra-peritoneal method, he had never once returned to the other plan, but he admitted that the mortality had been higher since the change, such increase, however, not being the fault of the operation, but due to exceptional complications. In the favourable cases there was a very striking contrast between the comfort of the convalescence after the one method and the discomfort after the other. He allowed that the question of mortality was of greater importance than that of comfort, but if, as was the case, the dangers attending the intra-peritoneal method were not greater than of the other, then the question of comfort deserved consideration. His plan of securing the vessels in the broad ligament was by tearing or otherwise forcing a hole in the ligament. At each extremity of the slit thus made he passed a silk ligature, tying the one over the free upper border of the broad ligament, and the other over the infundibulo-pelvic ligament, the latter securing the ovarian artery. The inner one prevented bleeding during the operation from the vessels on the uterine side of the broad ligament, and took the place of the inconvenient clamp forceps. The tissues between these two ligatures having been divided, the upper part of the tumour became free. The next step was to tie the uterine artery on each side. He felt for the pulsating vessel where it approached the side of the uterus, as near as possible to the level of the *os internum*, and secured it. He held, with Mr. Greig Smith, that it was preferable to include the surrounding tissues in the ligature to prevent slipping. With regard to the origin of the sepsis in the author's cases, he thought it was hardly justifiable to say absolutely that it was from the vagina, for this was, he urged, a less frequent cause of infection than was generally supposed. The conclusions he had arrived at from his experience of oöphorectomy were: (1) that it afforded an almost certain means of relieving all the more dangerous symptoms in cases in which active treatment was necessary, and in which removal of the tumour or tumours was either impracticable or likely to be attended with special difficulty or grave risk; (2) that it was unsuitable in cases where the tumours had attained a very large size, or had become œdematous, or had undergone cystic or other degenerative change; (3) that it was peculiarly applicable to cases in which the tumours were, for the most part, intra-pelvic, and in which operative interference was required for the relief or prevention of dangerous pressure symptoms; (4) that its field of usefulness was likely to become curtailed in proportion as the technique of abdominal hysterectomy improved, and the mortality of the latter operation diminished; (5) that, although in experienced hands its mortality was not high,

it should never be regarded or spoken of as a slight or minor operation; (6) that it was impossible to know beforehand whether it would be an easy or a difficult, or even a practicable, operation; (7) that the relief was not generally so prompt or convalescence so free from interruption as in an ordinary case of ovariectomy, or even of abdominal hysterectomy; (8) that before being submitted to the operation, a patient should be made fully aware of the uncertainties that specially attended it.

Dr. P. HORROCKS considered the extra-peritoneal method to be barbarous, and preferred the intra-peritoneal method on every ground. He had performed Baer's operation four times, with one death. He pointed out that all operations had been placed on a different footing now that they could almost guarantee asepsis by means of sterilisation of instruments. He questioned the correctness of the opinion that the cervical and vaginal secretions were the cause of fatal sepsis in the case mentioned, and he could see no advantage in putting a drainage-tube into the pelvis to draw off the small quantity of serum which might exude from the seat of the operation.

Mr. MERRIDITH said he was still in favour of the extra-peritoneal method of dealing with the stump which had given him very satisfactory results in the 100 cases in which he had used it. He usually removed the serrenceud and pin at the end of a week after paring away all the tissue external thereto, allowing it to drop back into the abdomen. He did not think there was any necessity to allow the external portion of the pedicle to become septic and in his own cases this certainly did not take place. It was extremely rare for its return to be followed by any rise of temperature. One objection to this plan was said to be the risk of causing abdominal obstruction, but he had never seen such a case nor had he ever tied the ureter by mistake, though he knew of a case in which this had happened. He admitted that there might be a small protrusion at the site of the stump but this could easily be controlled by an appropriate pad and need give rise to no inconvenience. He had only operated on one case by the intra-peritoneal method, but though it turned out all right he was not converted to the advantages claimed for this procedure. He said his mind was open to conviction but so far nothing had been advanced to lead him to consider the propriety of abandoning the extra-peritoneal method of dealing with the pedicle.

The PRESIDENT did not think they were yet within measurable distance of the time when the removal of a fibroid which was not giving rise to painful symptoms, nor was menacing life, could be considered a justifiable proceeding. The mortality of the operation would have to be infinitely smaller than it was at present to justify their advising removal, except in presence of urgent symptoms. No one was more strongly in favour of operative interference when necessary than he was, but in any case, he considered oophorectomy to be a very unsatisfactory operation. When an operation of some kind was necessary, he thought it was better for the patient to incur the slight additional risk and submit to total extirpation of the uterus. They did not know enough of intra-peritoneal methods at present to form a definite opinion. It certainly seemed that however careful, and however aseptic a surgeon might be, as evidenced by the absence of septic complications in other abdominal operations, there was always a possibility in these intra-peritoneal cases of septic mischief supervening. He did not believe that infection always took place from the vagina, the want of drainage having probably much more to do with it. One reason why vaginal hysterectomies did so well was because fluid could drain away. He suggested that the intra-peritoneal method would have to be greatly improved before it could be safely recommended for general adoption. It had been said that the extra-peritoneal operation was "barbarous," but most of them, he imagined, would prefer to preserve life by a barbarous operation than to lose it by a triumph of surgery. When the two operations were placed on an equal footing as regards mortality, then doubtless the extra-peritoneal method would die out.

Mr. HARRISON CRIPPS, in reply, agreed that they were still a long way from the time when they would be justified in recommending patients to submit to the removal of a fibroid which was giving rise to no pressure symptoms, or hæmorrhage. With fourteen or fifteen cases of his own, treated by the extra-peritoneal method, he had had one example of intestinal obstruction, and one of his

colleagues had met with a similar accident. In ordinary ovarian operations it was extremely rare. He believed that sepsis was very rare with the extra-peritoneal treatment of the stump, but he had had one such case among those dealt with by the internal method, and he had since seen another very unfortunate case of the kind. The question of where the sepsis originated was of great interest. He had not stated absolutely that it arose from the vagina, but he said he could not help regarding that canal with suspicion. When one had to do with a small tumour, say one weighing seven or eight pounds, it might be possible to pass a needle through the broad ligaments and apply a ligature before cutting through them, but with a large tumour, one weighing twenty-five pounds for example, the layers of the broad ligaments were much too widely separated for this to be practicable. The tension, indeed, was such that if one passed a ligature over the large veins it would probably cut through. He maintained, in conclusion, that the intra-peritoneal method had not yet been shown to be superior to the older method, and, under any circumstance, in future he proposed to leave in a drainage-tube for the first forty-eight hours.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

MEETING HELD FRIDAY, JANUARY 31ST, 1896.

The President, DR. LOMBE ATTHILL, in the Chair.

OVARIAN TUMOUR.

DR. ALFRED SMITH showed a unilocular ovarian tumour, the size of an adult head, which he removed from a child aged thirteen years. Recovery rapid.

DR. LANE wished to know if the patient had menstruated?

DR. SMITH replied that she had not.

EXHIBIT.

Sir THORNLEY STOKER exhibited the uterus with a number of attached tumours which he had removed from a patient, thirty-five years of age. The growths were fibromyomata, all apparently of interstitial origin, although five or six of them in the process of development had become sub-peritoneal and pedunculated. The substance of the uterine wall was the seat of a number of tumours, varying in size from a pea to an orange, and the pedunculated growths were from the size of a goose egg to one so large that it weighed 15 lbs. The entire weight of the parts removed, when drained of blood, was 19 lbs. 10 oz., and must, when full of blood, have been about 24 lbs. The circumference of the large pedunculated fibro-myoma was 34 in. in one direction, and 31½ the other. The growth had existed for six years, and had become so bulky as to render life intolerable. The operation performed was a supra-vaginal, intra-peritoneal, hysterectomy. The sutures securing the intra-ligamentous structures were, like the cervix, rendered sub-peritoneal by careful suturing of the peritoneum from the brim of the pelvis on one side to the other. The operation was an exceedingly protracted one, owing to the difficulty of securing the stump of the right broad ligament, which was invaded by a cyst in such a way as to necessitate its division close to the pelvic wall. The operation lasted 2½ hours, and the most remarkable fact elicited by it was that in spite of the age and enormous size of the tumours there were absolutely no adhesions. The condition of the patient from the time of operation to the date of meeting, ten days, was perfectly satisfactory. She had not even suffered inconvenience, and was practically out of danger.

The PRESIDENT said that the rapid growth in this case would be likely to lead him to think that the tumour was of a sarcomatous nature. While connected with the Rotunda, a case presenting some points in common with Sir T. Stoker's case had come under his notice. Sir Knowley Thornton at the time was over in Dublin, and, having seen the case, expressed the opinion that he would not care to touch it. He congratulated Sir T. Stoker on an operation calculated to uphold the reputation of Dublin as a school of surgery.

Dr. F. W. KIDD read notes of a case of so-called Elephantiasis, which will be found on page 255.

ECLAMPSIA.

Dr. HASTINGS TWEEDY read a paper on eclampsia, and contended that it, like uræmic convulsions, arose from retention products in the system, the normal resultants of tissue waste. This retention can be brought about in one of two ways, but both are concerned, as a rule, in its accomplishment. There may be either a diseased condition of the kidneys present, or else an increased formation of toxins. This latter factor is, during pregnancy, always present, and is in large part to be attributed to the growth of the fœtus. He stated that the proofs are convincing that convulsions do not owe their causation to the presence of toxins in the blood, but rather to the deposit of the poisonous substance in the nervous centres, and believed that it was quite possible to quickly remove this substance from the centres of danger by depleting the blood of its water, and so causing a current to flow in its direction from the nervous centres. Purging, sweating, or blood-letting would effect this; but the kidneys alone were to be relied on to directly get rid of the harmful substance. Of course the administration of fluids in any form would completely counteract any good effects which might follow the above line of treatment. Throughout the eclamptic seizure the patient on no account is to be allowed to lie on her back, for the so-called œdema of the lungs, constantly seen in cases which end fatally, has its origin in most instances in the drowning of these organs by fluids arriving to them from the mouth. The power to swallow is nearly always absent in eclampsia, and the process becomes absolutely impossible when a mouth gag is used. He contended that of all drugs, morphia given hypodermically in large doses (up to 2½ grs. in 24 hours), presented the greatest number of advantages with the fewest disadvantages in the treatment of eclampsia. All now knew that morphia had but slight if any effect on either the heart or kidneys. On the other hand, it limited the formation of toxins, controlled convulsions, dried up bronchial and salivary secretion, was a diaphoretic, and above all prevented the onset of labour. No greater danger could happen an eclamptic patient than that labour set in, and this is more particularly the case if it be induced artificially. Chloroform, chloral, and pilocarpine, all tended to kill in a manner similar to the eclamptic poison, and, therefore, ought not to be employed. Neither should any fluid, or even croton oil, be placed in the mouth, the patient being unconscious. In conclusion, he believed that it was attention to small details of treatment—perhaps on the lines indicated in the paper—that enabled some authorities to show results immeasurably superior to those of other, though both might be pursuing apparently a similar line of treatment.

Dr. HORNE said, notwithstanding Dr. Tweedy's contribution, he was still of the opinion that as regards the pathology of the disease they were as much in the dark as hitherto. In attributing the disease to toxins, they were, he believed, begging the question, for the presence of those toxins had not been demonstrated. As regards blood-letting, he could not understand how it was a treatment applicable to all cases—for instance, to one patient who was plethoric, and to another who was anæmic. He spoke favourably of the treatment of eclampsia by ½ gr. doses of morphia, or corresponding doses of opium. He also expressed himself in favour of croton oil—a drop being placed on the back of the tongue. He had experience of pilocarpine in one case, and, although, in that case he himself did not administer the drug, under its influence the woman rapidly developed œdema of the larynx. He did not assent to Dr. Tweedy's theory as to the elimination of ptomaines by blood-letting.

The PRESIDENT said that the danger of the convulsions is infinitely greater when they occur in the early stages than when they occur in the latter stages of labour. He had induced premature labour successfully in two or three cases. Under certain conditions he would be prepared to adopt the same line of treatment again. However, he regarded such a procedure as a very serious one.

Dr. ALFRED SMITH pointed out the fact that some German investigators were inclined to believe that acetones in the blood was the cause of eclampsia. The recognised treatment of eclampsia was by large doses of morphia.

Dr. SMYLY was of opinion that the difference of opinion on the question of the treatment of eclampsia arose chiefly from the habit of forming conclusions on the experience

gained of one or two or a dozen cases. No matter what the treatment they had recourse to, sometimes they would get a run of successful cases, and sometimes the reverse. To his mind the question of inducing premature labour or not, was, by no means, a practical one; for the induction of labour occupies considerable time, and causes great reflex action. He believed chloroform increased the tendency to death. If the patient's death was inevitable, he did not think it was a matter of great consequence whether she died in convulsions or not.

Dr. McWENEY did not think there was anything special about the eclamptic kidney or anything special about the toxæmic condition of the urine. He held with Bouchard that eclampsia was an auto-intoxication. He had not, when examining for Dr. Horne a specimen of eclamptic urine, the means of demonstrating toxins, otherwise than by experiments on animals. He said that in eclamptic urine albumen in a greater or lesser degree was always present. A microscopic examination of that fluid invariably revealed hyaline tube-casts. Bouchard proved that toxins could be eliminated by acting on the bowels; but the question of the administration of purgatives should be determined by the condition of the patient; and mentioned that small vessels had been found plugged with a tissue, structurally identical with the chorion.

Dr. LANE dwelt on the necessity for prophylactic treatment—dietetic treatment. He thought morphia inferior to pure opium. Dr. Lane made a passing reference to serum treatment.

Dr. PARSONS could not consider the treatment by chloroform a rational method, since it was well known that the drug depresses the higher cortical centres. By giving opium they were likewise introducing into the system a substance which exercises a depressing effect on the heart. Opium, however, was a less dangerous drug than chloroform. He failed to understand the advantage to be derived from sweating the patient, in face of the fact that Dr. Purser had assured him that there was more urea in one drop of urine than in as much sweat as would cover the body from head to foot. He regarded pilocarpine as simply a poison in this disease, since it paralyses the sensorium, already too depressed.

Dr. MACAN ridiculed the theory that attributed eclampsia to plugging of small cerebral vessels.

Dr. TWEEDY said that success in the treatment of eclampsia largely depended on attention to details. He mentioned many of those details—as, for instance, turning the patient on her side during administration of chloroform.

The Section then adjourned.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD WEDNESDAY, MARCH 4TH.

The President, Dr. ARGYLL ROBERTSON, in the Chair.

PATIENTS.

Dr. MICHAEL DEWAR showed a child who had been practically moribund from diphtheria, but who, after injection of antitoxin serum, had made a good recovery.

Dr. JAMES CARMICHAEL showed a boy, æt. 9, suffering from chronic peritonitis, who was recovering under treatment. On admission into the Sick Children's Hospital he had an extremely tubercular look, the abdomen was markedly distended, and he only weighed 43 lbs. In a short time his weight rose to 49½ lbs. The abdominal exudation was almost entirely solid. The question of surgical interference was discussed, but he was of opinion that it was unnecessary as the patient was progressing so favourably without it. Dr. Carmichael thought that surgical aid was only necessary if there was much tension in the abdomen or the patient was much debilitated.

Mr. JOSEPH BELL showed a boy, æt. 8, with double dislocation of the hip-joints of congenital origin.

Dr. CARMICHAEL showed for Dr. Burn Mu doch a child with patent ductus arteriosus, she had also acquired heart disease. There was no cyanosis.

SPECIMENS.

Mr. STILES exhibited specimens of Prof. Tavel's anti-diphtheritic serum, with Beck's syringe for injecting it.

The serum, it was alleged, kept sterile for any length of time.

Mr. CAIRD showed a specimen of perforation of the stomach. The patient had been suffering from symptoms which pointed to cancer of the pylorus, and one night perforation occurred. Although the patient seemed to be moribund with a temperature of 95°5', transfusion was tried. In three hours the pulse had become good and the temperature normal. Laparotomy was then performed, and a perforation of the stomach walls was found, close to the pylorus and in connection with a cancerous tumour. A tube was passed into the stomach and the contents removed. The peritoneal cavity was washed out. As the rent in the wall of the stomach could not be sewn up a Wertzels gastrostomy was performed, the stomach being also connected with the ilium by means of a Murphy's button. For twelve hours the patient did well, but was again seized with symptoms of perforation and died. After death it was found that a fresh extravasation of the stomach contents had occurred along the gastrostomy tube.

Dr. GIBSON showed three photographs of patients with ocular paralysis.

Dr. JAMES read a paper on

THE BLOOD IN DIABETES MELLITUS.

He said that the majority of observers had found that, although diabetes mellitus was a wasting disease, the blood of those suffering from it was richer both in corpuscles and hæmoglobin than normally was the case. For some years back he had made a series of observations on this point. Thus, out of thirteen cases, five presented over 6,000,000 red corpuscles, five over 5,000,000 two over 4,000,000, and in one case over 3,000,000. The hæmoglobin was 100 per cent. in three, 60 per cent. in eight, and over 50 per cent. in eight. If this increase in the corpuscular elements of the blood were due to diminution of its volume from the great loss of water the specific gravity to the blood would be altered. By Roy's method, however, no increase in the density of the blood could be determined. He thought that the increase must be attributed to the *vis medicatrix naturee*. As the organism lost so much of its oxidising material efforts were made by it to supply part of this loss by increasing the oxidising power of the blood. A parallel might be adduced from the effects of starvation. The increased appetite was also corroborative evidence, and especially the greater powers of digestion. He thought that the more vigorous the case the richer was the blood.

Dr. GIBSON pointed out what appeared to him to be a similar compensatory effort in cases of congenital heart disease.

Dr. PATON thought that Dr. James' methods were not satisfactory. The facts, however, were so marked that they must be regarded as accurate. The specific gravity of the blood generally varied with the number of corpuscles contained in it. If the corpuscles were formed in larger numbers in diabetes he failed to see where the proteid necessary for their fashioning came from, as an extra drain of proteid material was one of the chief results of the disease.

Dr. LEITH also spoke, and Dr. JAMES replied.

Dr. W. G. SYM read a paper on

OPHTHALMIA NEONATORUM.

He paid especial attention to its prevention. After reviewing the treatment by astringents, he stated that the secret of success lay in leaving no pus in the conjunctival sac. An ordinary hairpin was a better instrument than many that had been specially devised. A large number of individuals were rendered blind by this disease, a form of blindness which was easily prevented by proper attention to cleansing the eyes of the newly-born. In England it seemed to be more common than in Scotland, probably because there more labours were conducted by midwives alone than in Scotland. In certain States in America it was a criminal offence if the midwife did not call in a doctor if the child's eyes became affected. In Glasgow a pamphlet was handed to each couple registering a birth, in which instructions were given as to what should be done if the eyes of the child should become inflamed. A similar measure might with advantage be adopted in Edinburgh.

Dr. ARGYLL ROBERTSON and Mr. BELL spoke, and Dr. SYM replied.

LIVERPOOL MEDICAL SOCIETY.

MEETING HELD THURSDAY, FEBRUARY 27TH, 1896.

The President, DR. CATON, in the Chair.

CASES.

DR. RAWDON read notes of a "Case of Stricture of the Oesophagus" in a woman, *æt.* 48. The peculiarity of the symptoms consisted in the recurrent character of her attacks of difficulty in swallowing, which, at times, from being comparatively slight, became almost complete. The first stage in the operation of gastrostomy was performed, but the patient only survived 35 hours. At the post-mortem examination a piece of orange pulp, shaped like a cigar, was found to be impacted in the oesophagus immediately above the stricture. This was the more remarkable, as its presence was not suspected, an oesophageal tube having been repeatedly passed beyond the stricture. The stricture was due to infiltration of "new growth" in the submucous and muscular tissue. The viscera did not contain any "new growth," but the peritoneum, the pleura, and the pericardium were studded with numbers of malignant new growths, averaging the size of a pea.

REMOVAL OF THE LAMINÆ AND SPINOUS PROCESS.

DR. CARTER showed a patient, *æt.* 59, a sailor, who nearly six years ago had had the laminæ and spinous process of the fifth cervical vertebra removed by Dr. McCosh at the Presbyterian Hospital, New York. About nine months previously, on Oct. 24th, 1889, he had been knocked senseless by a tremendous blow on the right side of his head from a heavy iron shackle at the end of a pennant 5 ft. long, which was driven violently round in a gale of wind. He has no clear recollection of anything till the following Christmas Day, when he found himself in a hospital at Boston, U.S.A. He says that then his arms were tightly flexed across his chest, requiring some force to draw them away, that his legs and thighs also were flexed with the heels pressing against the buttocks, and that the head was bent, the chin touching the sternum, much pain being caused when the nurses raised it in order to wash him. These facts seem to be fairly reliable. Those as to anaesthesia are more general. He says he felt nothing in left arm or leg, but could feel on the right side as low as the groin. He had no control over the bladder or rectum. The right underwent a certain measure of improvement, but he could not stand on the day of the operation, and had to be held up to enable him to be photographed. In a short memorandum from Dr. McCosh as to his condition immediately preceding the operation it is stated that he could not stand alone, that the lower extremities were considerably atrophied, that they could not bear the weight of the body, and that he possessed but little power in legs or thighs, that the left forearm was flexed upon the arm and in a state of spastic rigidity and utterly useless, that the right upper extremity was also useless; that he could not use hand or forearm, and could not feed himself; that the head had dropped forward, the chin resting on sternum, and that there was no power to raise it, that there was severe pain in the arms, legs, and chest." That is the only statement referring to sensation. The statement continues: "Operation nine months after injury. Fifth cervical vertebra found displaced to right side; its spine being one inch to right of median line. Posterior arch of this vertebra removed. Dura mater found in a condition of hemorrhagic pachymeningitis much thickened; had been adherent to bone, on removal of which the dura bled freely. Dura also adherent to spinal cord which itself did not appear diseased. Cause of paralysis was probably products of inflammation pressing on spinal nerve roots." If the patient's account of the position of his arms on Christmas day, which was two months after the accident, can be relied on, as I think it can, it proves that a dislocation of the fifth cervical vertebra can occur without paralyzing the adductors of the humerus. It also proves that a patient can live for nine months with such a dislocation unrelieved. The condition of general atrophy which now affects all the muscles of the left shoulder, arm, and forearm is probably simply the result of disease. At present anaesthesia is limited to a small narrow strip on the ulnar side of the left hand. During his short residence in hospital the skin of the atrophied limb became the subject of purpura which affected no other part of the body. The

chin still drops on the sternum necessitating the use of a cage with sling to support the head in the upright position. The patient came to hospital for bronchitis and remained but a short time under treatment.

Mr. R. W. MURRAY related a case of "Abscess of the Temporo-Sphenoidal Lobe," following left middle-ear disease. The patient was a girl, *æt.* 7, and the symptoms were typical of this particular intra-cranial complication. The abscess, which contained 1 oz. of pus, was opened and drained. A month later, when the child had apparently completely recovered, she had a sudden convulsive seizure affecting the right leg, right arm, and the right side of the face, with loss of consciousness. The left temporo-sphenoidal lobe was again explored, and deep in its substance pus was reached, about a drachm escaping. Next day she was conscious, and there were no convulsions, but the day following there were occasional convulsive movements of the right side of the body, including this side of the face, together with some retraction of the head. The head became more retracted, and the child died two days later. At the autopsy the left temporo-sphenoidal lobe was found to be intensely inflamed and softened; both lateral ventricles and the fourth ventricle contained pus.

EPILEPSY RESULTING FROM LEAD-POISONING.

Dr. ALEXANDER DAVIDSON read a paper entitled "Epilepsy and other Cerebral Symptoms resulting from Lead-poisoning; also a Reference to the New Act enjoining Notification to the Home Office of Lead-poisoning." After drawing attention to the Act of Parliament, he narrated in detail a very severe case of lead-poisoning occurring in a painter who had been painting the interior of a ship. The large amount of white lead used and the confined atmosphere of the cabin and passages of the ship being extremely conducive to severe poisoning. The man was admitted to hospital on a Monday; at that time he complained of headache and behaved in an imbecile manner. He shortly became worse, had delirium and epileptic fits, the convulsions extending over the whole body; he became unconscious, the fits increasing in frequency, and he died on the Friday, that is, four days after admission. There was no kidney disorder, so that the fits could be fairly considered to be due to the lead. A chemical examination of the brain showed the presence of lead; it was estimated that half a grain was the amount present in the entire brain. Lead was also present in the liver and intestines. Dr. Davidson made some general remarks on the frequency of the various symptoms and on the prognosis and treatment of the condition.

Dr. BRADSHAW suggested that seeing there was such a small amount of lead present in the brain might not the convulsions be due to *anæmia*?

Drs. Dickinson, Barr, Rawdon, Carter, Manby, Professor Bryce, and the President took part in the discussion.

Dr. DAVIDSON replied.

France.

[FROM OUR OWN CORRESPONDENT]

PARIS, March 7th, 1896.

TUBERCULIN.

At the Académie de Médecine M. Grasset read a paper on the early diagnosis of phthisis in man by means of injections of tuberculin. Everyone understood the utility of detecting the nature of this malady in its incipient stage, but all practitioners are well aware that the diagnosis is far from being easy and conclusive, for the bacilli do not appear in the expectoration until a relatively late period. The difficulties are still further increased where the tuberculosis is seated in the bones, the brain coverings, &c. Consequently, a new sign, if it be sure and without danger, is not to be despised. Tuberculin seems to furnish these two conditions, as testified by that great authority, M. Straus, who declared that "this substance constitutes an excellent diagnostic means in incipient phthisis."

The tuberculin was furnished M. Grasset for his experiments by the Pasteur Institute, and the dose employed was infinitesimal but sufficient, 150th of a grain. The mode of using is simple. The patient is kept in bed two or three days and his temperature taken morning and evening and marked. The hypodermic injection is then made once a day for two or three days more in the thigh, and the temperature carefully registered three times a day. No abscess follows or any local irritation. M. Grasset cited a series of cases in which he was able to arrive at an exact opinion on the nature of the affection. A man, *æt.* 43, entered the hospital presenting symptoms of rachidian meningitis, without any external sign of lesion of the vertebræ. For four months he had been suffering from inter-costal pains, coming on in paroxysms, the spine was painful to pressure, especially over the dorsal vertebræ. The left eye showed symptoms of exophthalmia, while the upper lid dropped. The body had evidently been wasting for some time. The temperature was normal, but after the injection of the tuberculin, it rose to 100°. M. Grasset pronounced the case to be one of tuberculous meningitis.

A patient, *æt.* 23, presented the symptoms of Addison's disease. He had had a costo-vertebral cold abscess, which got well after operation. The bronzed colouring had commenced five months before he entered the hospital, and for the previous month he had a slight cough. At the apex of the lung in front, expiration was found to be slightly prolonged, and behind, vesicular expansion was diminished; there were no bacilli in the sputa. The temperature, which had been oscillating between 97° and 98°, rose to 100° six hours after the injection of tuberculin, justifying the tuberculous nature of the disease of the renal capsules.

After giving the details of several other cases (14 in all), the report concluded by stating that the results obtained warranted the prosecution of further clinical experiments which would permit the Academy one day to draw up instructions for diagnosis of tuberculosis in man by tuberculin as it has been called upon to do in the case of the bovine species.

M. Weber read, in answer to a letter from the Minister of Agriculture, consulting the Academy on the value of tuberculin as a means of diagnosing tuberculous disease in the bovine species, a report, of which the following is an abstract.

Tuberculin at the dose of from six to ten grains provokes in tuberculous animals a rise of temperature attaining from two to five degrees, a reaction sufficient to affirm the existence of tuberculous lesions, in no matter how slight a degree, whereas the same dose has no appreciable effect on non-tuberculous animals, although they may be attacked by grave lesions of the lungs or of the other viscera. The febrile reaction appears between the twelfth and fifteenth hour after the injection, and lasts several hours. It was said that tuberculin produced no reaction in certain animals recognised tuberculous at the autopsy. The fact is true, but these animals are always in such an advanced stage of the malady that the diagnosis is easily made by the ordinary methods of examination without having recourse to tuberculin. The reproach was also made that tuberculin hastened the evolution of the disease. This objection has no foundation, for tuberculin presents no danger to the animal.

Nothing is so easy to day than the removal of tuberculous disease from a stable; it is sufficient to submit all the

animals to the tuberculin test, separate the healthy animals from all those which show a reaction after the injection, disinfect the stable, and allow no animal to enter it without careful examination.

In concluding, the speaker proposed the following resolution:—"Tuberculin is an excellent means of establishing the diagnostic of bovine tuberculosis, and its employment should be recommended." (Adopted).

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, March 6th.

MEDICAL EDUCATION—LUNACY REQUIREMENTS.

THE Minister of Education has lately surprised the medical world by an order bearing on the education and examination of *public medical officers*. The order is supposed to be an outcome of the unfortunate Alexianer lunacy scandal. For the future candidates for these offices will be required to attend a course of lectures on psychiatry at a German University and to attend the practice of a lunatic hospital for six months, or to hold office as interne of such a hospital for three months. A hospital in which such lunacy practice is taken out must not have fewer than 150 mental cases yearly. The order comes into force in October of the present year, and it will apply to all candidates who are not already in their last year of study. It is not understood to be the intention of the Minister to raise the salaries of its medical officers as a compensation for the increased cost of education in this way imposed upon them.

RESORPTION OF THE SALTS OF IRON.

In the *Zeitsch. f. Physiolog. Chemie*, Hr. Woltering has a paper giving the results of an inquiry into the resorbability of iron salts into the system. He first repeated Kunkel's experiments, and found that when iron was given to mice, rabbits, or dogs, by the mouth, it accumulated in the liver; that in fact the liver was possessed of the faculty of storing up iron. The question then arose as to the form in which it was thus stored up. The author found that one of the combinations was a nucleoprotein. In this form it was firmly associated and could not be discovered without destroying the substance. He found also by later experiment that the accumulation of iron resulted directly from resorption and not from any property of preventing waste.

A further question was whether the organism could make use of the accumulated iron in case it required it for the production of hæmoglobin, and the author's opinion is that it can. On withdrawing blood from animals fed with iron, and others as check animals, he found that the blood corpuscles did not fall so low in the former class as in the control animals. The blood returned to its normal state much more quickly and completely in the animals possessed of accumulated iron than in the others. It was very noticeable also that in the livers of the animals not fed with iron there was much less of it than in the others, and that in the iron animals the quantity was equal to, if not above, the normal amount. The author does not state how long a time is required for the organism to use up its surplus iron stored in this way.

FORMALINE GELATINE—A NEW MODE OF ANTISEPTIC TREATMENT.

In the *Therapeut. Monatsch.* (2-96), Dr. Schleich relates his experiences in the use of formaline gelatine in the

treatment of wounds. The formaline gelatine is prepared by drying gelatine dissolved in water over formaline vapour. A firm resistant stony hard transparent body is thus formed. The question first to be decided was whether the gelatine would gradually dissolve and give off its formaline, and in this way set up a continued state of asepsis in its neighbourhood. In the first experiment resection of intestine was performed on a rabbit, and before closing the abdominal wound a piece of formaline gelatine the size of an apple was introduced into the abdominal cavity. The animal was killed six and a half weeks later and only a minute remnant of the gelatine was found in the midst of newly-formed connective tissue. Further experiments were modified by the author to the extent that a quantity of virulent bacteria cultures was mixed with finely powdered formaline gelatine and introduced into the system, all of which were absorbed without any reaction. These results led the author to use the gelatine in the treatment of wounds in the human subject. It was used in the form of powder, and Hr. Schleich became satisfied that it was gradually decomposed with continuous freeing of formaline, and consequent steady asepticism of the wound. Up to the time of writing he had used it in 120 cases of acute suppuration, 93 aseptic healings of wounds, 4 compound fractures, and 2 deep scalp wounds, and he was in a position to state that by its means, all acute suppurations were cut short, and that in every wound an aseptic course could be guaranteed without the adoption of any further measures. Where necrotic tissue was present, however, it was powerless, as contact with sound tissue alone was able to set free the formaline. In order to render it serviceable in such cases a means must be discovered of setting the formaline free outside the body, and such a means has already been found by the author in a peptic acid solution (pepsin 5 parts, acid hydrochl. 0.3 parts, water to 100, distill). The powder with which the wound is powdered requires moistening with the above pepsin solution. The mode of preparation of the formaline gelatine is given by the author.

The fact that when the gelatine was enclosed within the system it became eventually completely replaced by connective tissue led the author to still further experiments. These led to the conclusion that formaline gelatine, being procurable in any shape, and on being heated capable of being moulded to any form, it might be employed for the plastic connective tissue closure of defects of all kinds. Impregnated with lime salts, it proved itself capable of replacing pieces of bone removed in the course of resection.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, Mar. 6th, 1896

OPERATIVE TREATMENT OF LUPUS VULGARIS.

RILLE showed at the Gesellschaft two cases from Neumann's clinic which had been treated for lupus vulgaris by total extirpation of the morbid surface and showing plastic repair induced by transplantation after Thiersch's method of grafting. The first patient was 48 years of age, and had been troubled with the disease for the last 15 years. The infiltrated lupous surface extended on the right side of the face from the ear to the nose and from the lower angle of the jaw to the lower margin of the eyelid. The case was a favourable one for operation, owing to the disease

not having involved the mucous membrane of the nose, mouth, or eye. There was no ectropium present as the result of a contracting cicatrix.

Under chloroform an incision was made around the circumference of the morbid area about three-quarters of a centimetre beyond the morbid structure into the healthy tissue. The whole lupous tissue was carefully dissected off with very little loss of blood, only three or four ligatures being applied, torsion having sufficed to check hæmorrhage throughout the operation. The whole surface denuded in this way was 11 centimetres by 6 centimetres which was immediately after strewn over with lamellæ of graftings taken from the upper part of the leg as directed by Thiersch, each lamella measuring 2 centimetres broad. Before the dressing [were, for the first time, removed the wound was almost closed, and by the end of the first month was completely healed leaving a dark pigmented surface which Rille accounted for by the deep removal of the tissue.

The second case was that of a young woman, æt. 18, affected in the same way as the preceding, and treated in the same manner with favourable results. This patient had several other patches of lupus on the extremities which had been treated by excision. Since Thiersch introduced this method of treatment in 1836 many remarkable cases of healing have been recorded by his admirers, among whom are Urban, Bergmann, Socin, and more recently, Steida. In Vienna, Prof. Lang has recorded many severe cases complicated with lupus, which have been completely restored. Grafting in this disease seems to proceed more speedily in the repair of ulcerated tissues than in other defects of the cuticular surface.

CONGENITAL HYDROPHTHALMUS AND IRIDECTOMY.

Bergmeister exhibited a patient on whom he had performed iridectomy thirteen years ago, on account of infantile glaucoma. The patient was born in 1882, and in March 1883, the mother observed that the cornea of the left eye was gradually becoming dull and white. On admission into hospital, the whole cornea was cloudy, the globe hard and resisting and greatly enlarged, particularly in the anterior section, while the cornea appeared to be bent, indicating the beginning of keratoglobus, was diagnosed as infantile glaucoma, and forthwith iridectomy was performed. This operation, when high tension is present in the bulbus, has often been commended and condemned in infantile glaucoma. The advocates of the latter maintain that serious consequences will ensue when iridectomy is performed by the extension of the vitreous humour which will in all probability occur owing to the great distension of the iris and zonule of Zinn which would easily allow the lens and contents of the globe to bulge forward under pressure with the eventual changes of panophthalmitis. It must be borne in mind, however, that these consequences only occur in cases where the degeneration of the eye has already far advanced. In this young patient the operation was undertaken at an early stage of the disease. After chloroform was administered the cornea was quite opaque, but on the following day after the operation it became quite clear and the wound healed speedily. The patient was lost sight of for eight years and when seen in 1890 the eye appeared quite normal, and now, thirteen years after the operation we may confidently declare it successfully cured.

Telaky thought that Bergmeister's operation was an encouragement; to perform [the operation. He related a

similar case which he had treated with eserine and apparently checked the progress of the disease, but subsequently left a buphthalmus eye which had finally to be enucleated.

The Operating Theatres.

ST. THOMAS'S HOSPITAL.

CÆSARIAN SECTION.—Dr. CULLINGWORTH performed this operation on a woman, æt. 36, who, he said, might be described as a rickety dwarf. As a child she had been put out to nurse, and only walked when 7 or 8 years old. She married when 26; her first pregnancy terminated at seven months in a miscarriage; at the second, in 1887, craniotomy was performed at the full term; for the third, in 1888, craniotomy was also done, as the patient failed to come up at the end of the seventh month as advised for the induction of premature labour; at the fourth, in 1889, premature labour was induced at the end of the seventh month; induction of premature labour at the seventh month and craniotomy was resorted to for the fifth in 1892. The present operation was performed at the end of the thirty-ninth week from the date of the cessation of the last menstruation. The estimated true conjugate diameter was 3 inches $\frac{3}{4}$, the diagonal conjugate being 3 inches $\frac{1}{2}$. The operation was performed without waiting for labour to begin. The ordinary incision about five inches long was made. The uterus was found tilted over, so as to be with its anterior surface to the right, whilst the left uterine appendages were in the middle line in front; the position of the organ was first of all rectified, and then an assistant held it in position whilst the uterine incision was made, the abdominal wall being thus held closely in contact with the uterus, prevented any fluid from obtaining access to the peritoneal cavity. The uterus was laid open *in situ* by an incision of about four inches, the attitude of the child and the position of the placenta having been previously diagnosed; the bulging membranes were ruptured, the hand passed rapidly into the organ, and the child's head grasped and brought to the opening, which was just large enough to allow the head to pass; the remainder of the child was easily extracted. The cord was clamped in two places and divided between them. The child was handed to an assistant and cried almost immediately; it was a female, 5 lbs. 14 oz. in weight, and 20 inches in length. The placenta and membranes were now removed by grasping them in the hand and allowing the uterus to contract upon the hand. The finger was then passed into the cervical canal to make sure it was sufficiently patulous to give exit to the lochia. No douching or swabbing of the uterus was employed. The uterus was next brought out of the abdominal cavity and protected with hot sponges while the sutures were being introduced. The sutures used were of silk, and the plan of introduction the one advocated by Dr. Howard Kelly, of Baltimore, namely, by a row of deep sutures passing through the whole of the uterine wall excepting the decidua, and then, instead of the usual row of superficial sutures, a series of half-deep sutures one between each two of the deep ones. The uterus was now well contracted and was returned within the abdomen. There was very little bleeding during the operation; once it was necessary for the assistant to compress the cervix between his two hands for a minute or two, which had the effect of controlling the hæmorrhage at once. No toilet of the peritoneum was necessary. The abdominal wound was

closed with silkworm gut sutures in the usual way, the omentum having been drawn down so as to be between the uterus and the abdominal wound. The operation, including the suturing, occupied fifty minutes, and the patient bore it exceedingly well. Dr. Cullingworth remarked on the obliquity of the uterus and the necessity of holding it so that the incision was made in the middle line of the anterior wall, as the side walls were very much thicker and contained many large vessels.

ST. GEORGE'S HOSPITAL.

OVARIOTOMY.—EXTENSIVE ADHESIONS.—Mr. HERBERT ALLINGHAM operated on a woman, *æt.* about 35, whose previous history was that about ten years ago she had been tapped several times for supposed ascites. Since then the abdomen had gradually enlarged, until at the time of the present operation, when it was enormous; it was dull on percussion right up to the ensiform cartilage, but slightly resonant in both loins. The belly was opened in the middle line below the umbilicus, and it was found impossible to differentiate the parietal peritoneum from the cyst, which was found adherent to it. The cyst was therefore opened and the incision carried up to the ensiform cartilage, in the hope that by so doing the surgeon would be able to find the upper limit of the cyst, and thus it would be possible to separate it from the abdominal parietes. It was found, however, that the cyst was firmly adherent to the under-surface of the liver and to the intestines, so that it was impossible to separate the adhesions without tearing into these parts. In a like manner the cyst was adherent to all the structures at the back part of the abdomen. Mr. Allingham therefore considered it would not only be very dangerous, but also absolutely impossible to remove the cyst. Accordingly the upper and lower parts of the abdominal incision were closed, the centre part of about three inches being left open so as to ensure sufficient drainage. Mr. Allingham hoped that by keeping the interior of the cyst aseptic, in time the walls might adhere together, and so the enormous cavity become obliterated. He considered that the repeated tapping which had been done many years ago had been the cause of extensive peritonitis, which had glued the cyst everywhere to the interior of the abdomen, and so rendered simply impossible the removal, which ought to have been an ordinary procedure, as the cyst was unilocular. He commented on the necessity of very free drainage in such a case as the only chance for the patient.

GREAT NORTHERN HOSPITAL.

OPERATION FOR EPITHELIOMA INVOLVING THE FLOOR OF THE MOUTH.—Mr. HERBERT ALLINGHAM operated on a man, *æt.* 53, who suffered from a growth situated about the sublingual gland and encroached slightly on to the tongue. In the submaxillary region there was a mass of enlarged glands. He commenced by making a long incision from the angle of the jaw to the apex of the chin, and then thoroughly cleared out the enlarged glands in the submaxillary triangle. After this another incision was carried up to the angle of the mouth and the cheek reflected; the jaw was then sawn through about the position of the first bicuspid tooth, which proceeding gave free access to the floor of the mouth; the growth was freely excised, and a considerable amount of the base of the tongue also removed. The jaw was drilled and wired together, and the soft parts replaced and kept in *situ* by stitches. Mr. Allingham remarked on the importance of first removing all the diseased glands in the neck, and also pointed out the great advantage of dividing the jaw so that the growth about the floor of the mouth was freely exposed to view and could easily and freely be dealt with.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 11, 1896.

THE ETIQUETTE OF PROFESSIONAL ADVERTISING.

THE case to which we briefly alluded last week, in which a medical man sued the Editor of the *British Medical Journal* for libel and obtained damages for £180, was the means of bringing under the notice of the public several important matters, with which it is now our intention to deal. In the first place, it may be observed that, so far as the "libel" itself is concerned, we have nothing special to say. It was decided against our contemporary, but our conviction is that the Editor was deceived as to the extent of local feeling which existed against the plaintiff, and thus, perhaps, was led into expressing himself in somewhat stronger terms than he otherwise would have done. It must, also, be admitted that the case for the defence was scarcely as well managed as it might have been. The defence was decidedly weak in the witnesses, and the mention of this matter brings us to the consideration of one of the most important features, the exposure of which has excited so much comment in the public press. The feature to which we allude is the evidence of no less a personage than the Treasurer of the Royal College of Physicians of London, Sir Dyce Duckworth. From the pedestal of his exalted position he came to bless the defendant, but in the end it was a curse

which fell upon the luckless head of the latter. The jury could not be hoodwinked in a matter of common-sense, even by so mighty an official as the Treasurer of the Royal College of Physicians. The opinion of Sir Dyce Duckworth on the case, as given in his evidence, was that "it was objectionable to advertise a medical man's name in connection with an hotel, and it was undesirable, even in the case of a hydropathic establishment." So far, so good. But what did his cross-examination elicit? It was pointed out to him that his own name, together with the hospital with which he is connected, and his private address appeared in an insurance prospectus, which was widely circulated, and placed in large numbers on office counters, and even hung in picture frames upon the walls of hotels and other public places. In reply, however, Sir Dyce Duckworth denied that such a practice amounted to advertising. "His private address," he added, "was given for the convenience of those who had to see him." Here is a case of Tweedledum and Tweedledee. How was it to be supposed that the jury could have heard this evidence without smiling. Could anything have displayed more clearly the readiness with which medical men in high places elaborate an excuse when a charge of advertising is brought against themselves, and how keen they are to condemn an unfortunate general practitioner who has overstepped the line of ethical conduct in, perhaps, a less offensive kind of way. Truly, it would seem that there is one law for the rich and another for the poor, so far as the question of advertising by members of the medical profession is concerned. In view, however, of the deliberate pronouncement of its Treasurer, in this matter, we should like to know what the Royal College of Physicians considers is, and what is not, advertising. The profession is always led by the officials of the Institution to believe that its Fellows are an immaculate community of commercially pure-minded persons, whose last thought in the world would be that of parading themselves before the public. We sadly fear, however, that whatever the ideal may be in this respect, few attain to it. Indeed, the Fellows of the College must admit that many of their best known colleagues are, in this respect, Pharisees. The case of "Kingsbury v. Hart" has done good in one sense, it has shown the public that whenever a practitioner holding the position of Sir Dyce Duckworth allows himself to be advertised in a shameless manner, nothing is said of it by his compeers, but when a hapless medical man in a small country town adopts any species of self-advertisement, the hands of the powers that be are held up in horror at the iniquity of the offence, and he is condemned accordingly. The truth of these facts became so apparent at the trial during the cross-examination of Sir Dyce Duckworth that a lay contemporary waxed merry over the inconsistency which was displayed. But the trial has virtually decided another point. Practitioners who were fearful of incurring the wrath of the Royal Colleges may now, on the authority of Sir Dyce Duckworth, indulge in a good deal of advertising. They have his authority for it that if they can secure the good offices of a friend to send their names,

addresses, and qualifications broadcast over the land, they cannot be held guilty of offence, for has not the Treasurer of the Royal College of Physicians, London, denied on oath that this practice amounted to advertising? He did not add in his evidence, "Go, and do thou likewise," to the members of his profession, but that was to have been expected. That is precisely where the Royal College of Physicians, London, draws the line in this matter.

THE ARMY MEDICAL COMPETITIVES.

WE understand that the Royal College of Surgeons of Ireland and the University of Dublin, possibly with the co-operation of the Royal University, have taken steps to open up the whole subject of these examinations by a discussion upon the Army Estimates, which appear on the Notice Paper of the House of Commons for to-morrow (Thursday). The salient fact is that these examinations are no longer competitive, inasmuch as the demand for admission to the Army Medical Service has come to be so small that there are more vacancies than candidates, and, in fact, the breaches in the ranks of the Service cannot be filled. This, in a general way, is the natural outcome of the policy of the depreciation of the Medical Department of the Service which the Duke of Cambridge pursued, and which, we regret to observe, his successor, Lord Wolseley, and his assistant, Sir Redvers Buller, have perpetuated. It has been, for years, the policy of the heads of the combatant Departments to snub and depreciate "those d—d doctors," and, naturally, the combatant officers, who are dependent on the goodwill of these chiefs, have willingly followed the cue and done likewise. It is as recently as the last distribution of prizes at Netley that Sir Redvers Buller, quite gratuitously, took occasion to remind the assembled probationers that an Army Medical Officer is only a doctor after all, and that he had better stick to his duty, like an Army cook, and not seek to raise himself to the social or service level of the combatant, whose rank he is supposed to hold.

This policy of depreciation, however, strikes all Army doctors of all nationalities equally, and it is not the special reason for the intervention of the Irish Licensing Bodies. They complain, though they will not put the complaint upon the face of their official communications, that Irish candidates are subjected to an organised "boycott." What they cannot say diplomatically, we take liberty to say for them. It will be recollected that, in the year 1893, a scandalous job was perpetrated by the War Department, for the purpose of giving the London teachers predominance, at this examination, over all others. It was then decreed that the competitive examiners should be selected, exclusively, from the London Conjoint Board, the obvious effect of which arrangement was to ensure that the candidate, if he desired to find favour, must frequent the London hospitals, especially those to which the Army examiners happened to be attached. So unfair an arrangement called at that time into action the College of Surgeons of Ireland, which presented strong remonstrances to the War Office but these representa-

tions produced no effect save a promise which never was fulfilled, because neither the Irish Universities nor the Scotch Colleges lent any useful aid. The grievance has still existed, and has increased. The Army Service papers have avowed that the competitive examiners are bound to weed out, and do weed out, Irish candidates, for the simple reason that they present Irish qualifications, and the facts and figures support the assertion. The examiners are supplied upon the marking papers with the names and qualifications of the candidates, and they know that if they give a "sticking" mark upon the answering, the objectionable candidate will be excluded. That they have been in the habit of giving such "sticking" marks to the Irish candidates is shown by the returns made to the General Medical Council by the Army Medical Department. For the two examinations of 1895, forty candidates presented themselves who held thirty-seven English qualifications, and only twelve Irish and fifteen Scotch. It will thus be observed how the boycott has operated to secure a monopoly of these examinations for the London School. It is, however, more manifest upon scrutiny of the relative numbers of each nationality who passed for commissions. It appears that twenty-four out of the thirty-one London qualifications secured 77 per cent. of the prizes, while only four out of eleven Irish qualifications (*i.e.*, 36 per cent.) were equally successful, and twelve out of eighteen (66 per cent.) for Scotch qualifications. Taking the two examinations together it is observable that the rejection percentage was for Irish-English candidates 25 per cent., for Irish 58 per cent. We cannot, of course, be certain that the Irishmen were as well educated as the Englishmen at these examinations, but suspicion of the *bona fides* of the examination is aroused by the observation that the candidates holding qualifications from the highest Irish qualifying bodies, the University of Dublin, for instance, have habitually suffered rejection at the same examinations at which those from the London Apothecaries' Company passed and obtained commissions. We trust that the communications which the Irish colleges now make to the War Office on the subject will be something more than the interchange of diplomatic courtesies which in the past have failed to produce any satisfactory result. Either the Irish candidates are fit for Army service or they are not. If they are, the Irish Colleges should ensure that their men have every chance of obtaining admission to the Service which is enjoyed by those of English and Scotch Colleges; if they are not, it certainly behoves the Colleges to free themselves and their schools from the stigma attaching to the frequent rejection of their diplomates.

 We learn that, for the purpose of making representations on this subject, deputations have proceeded from Dublin to London. For the Irish College of Surgeons, Sir Thornley Stoker, President, Mr. Thomson, Vice-President, and Mr. William Stoker, Councillor and for the University of Dublin, Mr. Ball, Regius Professor of Surgery, and Dr. Cunningham, Professor of Anatomy.

POOR-LAW MEDICAL SUPERANNUATION.

THE Bill introduced by the English Union Medical Officers' Association stands for second reading on the 18th of March, and it is hoped that it will pass this stage without serious opposition. A request will be then made for the extension of the Bill to Ireland, and it is expected that the promoters of the Bill, who long since expressed their willingness that it should be so extended, will accede to the proposition, unless they see that it is threatened with serious opposition. It is also anticipated that both the English and Irish Local Government Boards and the Chief Secretary will also approve of the Bill, subject, of course, to slight amendments when it gets into Committee. To promote these arrangements the Irish Medical Association has been taking active steps in order to obtain the concurrence of the Boards of Guardians, and the Irish Union Officers' Association is co-operating with it. An epitome of the Bill has been sent to every Board of Guardians in Ireland with a letter to the Clerk of Union asking him to submit it to his Board and to secure, if possible, the passing of a resolution in favour of the Bill. At the same time a copy of these communications has been sent to every Poor-law Medical Officer with the request that he will bring pressure to bear upon his guardians for the same purpose. The effect of these efforts by the Irish Medical Association has been, so far, quite encouraging. The time has been too short to allow of answers being received in most cases, but up to last Saturday about twenty Boards had signified their approval, and only one (Trim) refused it, on what grounds no one knows. The next step in the movement is to bring the influence of the guardians and others to bear on the Irish Members, and this will be done the moment the answers of a sufficient number of Boards have been received. If the second reading of the Bill should pass for England, as is confidently expected, it will become necessary to move, when it is passing through Committee, the insertion of a clause to extend it to Ireland, and to make it suitable to the special conditions of Irish Poor-law, and such clause is now in preparation by Parliamentary counsel on behalf of the Irish Association, and if the Bill passes with the addition of this clause, the weary superannuation question will have been settled on a somewhat satisfactory basis.
